HPX Documentation

2.0.0

The STE||AR Group

September 11, 2026

USER DOCUMENTATION

Welcome to the *HPX* documentation!

If you're new to *HPX* you can get started with the *Quick start* guide. Don't forget to read the *Terminology* section to learn about the most important concepts in *HPX*. The *Examples* give you a feel for how it is to write real *HPX* applications and the *Manual* contains detailed information about everything from building *HPX* to debugging it. There are links to blog posts and videos about *HPX* in *Additional material*.

You can find a comprehensive list of contact options on Support for deploying and using HPX[1]. Do not hesitate to contact us if you can't find what you are looking for in the documentation!

See *Citing HPX* for details on how to cite *HPX* in publications. See *HPX users* for a list of institutions and projects using *HPX*.

There are also available a PDF version of this documentation as well as a Single HTML Page.

CHAPTER ONE

WHAT IS *HPX*?

HPX is a C++ Standard Library for Concurrency and Parallelism. It implements all of the corresponding facilities as defined by the C++ Standard. Additionally, in *HPX* we implement functionalities proposed as part of the ongoing C++ standardization process. We also extend the C++ Standard APIs to the distributed case. *HPX* is developed by the STE||AR group (see *People*).

The goal of *HPX* is to create a high quality, freely available, open source implementation of a new programming model for conventional systems, such as classic Linux based Beowulf clusters or multi-socket highly parallel SMP nodes. At the same time, we want to have a very modular and well designed runtime system architecture which would allow us to port our implementation onto new computer system architectures. We want to use real-world applications to drive the development of the runtime system, coining out required functionalities and converging onto a stable API which will provide a smooth migration path for developers.

The API exposed by *HPX* is not only modeled after the interfaces defined by the C++11/14/17/20 ISO standard. It also adheres to the programming guidelines used by the Boost collection of C++ libraries. We aim to improve the scalability of today's applications and to expose new levels of parallelism which are necessary to take advantage of the exascale systems of the future.

HPX is a member of the High-Performance Software Foundation (HPSF[2]) network, which signals its commitment to the open-source, high-performance computing (HPC) community. By joining HPSF[3] - and, concurrently, the Linux Foundation - HPX gains access to a broader collaborative ecosystem that promotes shared standards, interoperable tools, and joint research initiatives, all of which accelerates the development of scalable parallel applications. This dual affiliation enhances HPX's credibility, attracting contributors and industry partners who value the rigorous governance and transparent development practices upheld by both organizations. Consequently, HPX can more effectively influence the direction of future HPC frameworks while benefiting from the collective expertise, resources, and industry backing provided by HPSF[4] and the Linux Foundation.

CHAPTER

TWO

WHAT'S SO SPECIAL ABOUT *HPX*?

- HPX exposes a uniform, standards-oriented API for ease of programming parallel and distributed applications.
- It enables programmers to write fully asynchronous code using hundreds of millions of threads.
- HPX provides unified syntax and semantics for local and remote operations.
- HPX makes concurrency manageable with dataflow and future based synchronization.
- It implements a rich set of runtime services supporting a broad range of use cases.
- HPX exposes a uniform, flexible, and extendable performance counter framework which can enable runtime adaptivity
- It is designed to solve problems conventionally considered to be scaling-impaired.
- HPX has been designed and developed for systems of any scale, from hand-held devices to very large scale systems.
- It is the first fully functional implementation of the ParalleX execution model.
- HPX is published under a liberal open-source license and has an open, active, and thriving developer community.

2.1 Quick start

The following steps will help you get started with *HPX*. Before getting started, make sure you have all the necessary prerequisites, which are listed in _prerequisites. After *Installing HPX*, you can check how to run a simple example *Hello, World!*. *Writing task-based applications* explains how you can get started with *HPX*. You can refer to our *Migration guide* if you use other APIs for parallelism (like OpenMP, MPI or Intel Threading Building Blocks (TBB)) and you would like to convert your code to *HPX* code.

2.1.1 Installing *HPX*

The easiest way to install *HPX* on your system is by choosing one of the steps below:

1. **vcpkg**

   You can download and install *HPX* using the vcpkg[5] dependency manager:

   ```
   $ vcpkg install hpx
   ```

2. **Spack**

   Another way to install *HPX* is using Spack[6]:

[5] https://github.com/Microsoft/vcpkg
[6] https://spack.readthedocs.io/en/latest/

```
$ spack install hpx
```

3. **Conan**

   You can also use the Conan[7] package manager to build and use *HPX* in your projects. First, export the *HPX* recipe from the *HPX* repository to your local Conan cache:

```
$ git clone https://github.com/TheHPXProject/hpx.git
$ cd hpx
$ conan create . --build=missing
```

   This builds *HPX* and makes it available in your local Conan cache. You can then use it in your Conan-based projects by adding it to your `conanfile.txt`:

```
[requires]
hpx/2.0.0

[generators]
CMakeDeps
CMakeToolchain
```

   Then use `find_package(HPX REQUIRED)` in your `CMakeLists.txt` as usual. Conan will automatically handle building *HPX* with your chosen configuration options and provide the necessary CMake integration files.

4. **Fedora**

   Installation can be done with Fedora[8] as well:

```
$ dnf install hpx*
```

5. **Arch Linux**

   HPX is available in the Arch User Repository (AUR)[9] as `hpx` too.

More information or alternatives regarding the installation can be found in the *Building HPX*, a detailed guide with thorough explanation of ways to build and use *HPX*.

2.1.2 Hello, World!

To get started with this minimal example you need to create a new project directory and a file `CMakeLists.txt` with the contents below in order to build an executable using CMake[10] and *HPX*:

```
cmake_minimum_required(VERSION 3.19)
project(my_hpx_project CXX)
find_package(HPX REQUIRED)
add_executable(my_hpx_program main.cpp)
target_link_libraries(my_hpx_program HPX::hpx HPX::wrap_main hpx::iostreams_component)
```

The next step is to create a `main.cpp` with the contents below:

[7] https://conan.io/
[8] https://fedoraproject.org/wiki/DNF
[9] https://wiki.archlinux.org/title/Arch_User_Repository
[10] https://www.cmake.org

```cpp
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Then, in your project directory run the following:

```
$ mkdir build && cd build
$ cmake -DHPX_DIR=</path/to/hpx/installation> ..
$ make all
$ ./my_hpx_program
```

```
$ ./my_hpx_program
Hello World!
```

The program looks almost like a regular C++ hello world with the exception of the two includes and `hpx::cout`.

- When you include `hpx_main.hpp` *HPX* makes sure that `main` actually gets launched on the *HPX* runtime. So while it looks almost the same you can now use futures, `async`, parallel algorithms and more which make use of the *HPX* runtime with lightweight threads.
- `hpx::cout` is a replacement for `std::cout` to make sure printing never blocks a lightweight thread. You can read more about `hpx::cout` in *The HPX I/O-streams component*.

Note

- You will most likely have more than one `main.cpp` file in your project. See the section on *Using HPX with CMake-based projects* for more details on how to use `add_hpx_executable`.
- `HPX::wrap_main` is required if you are implicitly using `main()` as the runtime entry point. See *Re-use the main() function as the main HPX entry point* for more information.
- `hpx::iostreams_component` is optional for a minimal project but lets us use the *HPX* equivalent of `std::cout`, i.e., the *HPX The HPX I/O-streams component* functionality in our application.
- You do not have to let *HPX* take over your main function like in the example. See *Starting the HPX runtime* for more details on how to initialize and run the *HPX* runtime.

Caution

Ensure that *HPX* is installed with `HPX_WITH_DISTRIBUTED_RUNTIME=ON` to prevent encountering an error indicating that the `HPX::iostreams_component` target is not found.

When including `hpx_main.hpp` the user-defined `main` gets renamed and the real `main` function is defined by *HPX*. This means that the user-defined `main` must include a return statement, unlike the real `main`. If you do not include the return statement, you may end up with confusing compile time errors mentioning `user_main` or even runtime errors.

2.1.3 Writing task-based applications

So far we haven't done anything that can't be done using the C++ standard library. In this section we will give a short overview of what you can do with *HPX* on a single node. The essence is to avoid global synchronization and break up your application into small, composable tasks whose dependencies control the flow of your application. Remember, however, that *HPX* allows you to write distributed applications similarly to how you would write applications for a single node (see *Why HPX?* and *Writing distributed applications*).

If you are already familiar with `async` and `future` from the C++ standard library, the same functionality is available in *HPX*.

The following terminology is essential when talking about task-based C++ programs:

- lightweight thread: Essential for good performance with task-based programs. Lightweight refers to smaller stacks and faster context switching compared to OS threads. Smaller overheads allow the program to be broken up into smaller tasks, which in turns helps the runtime fully utilize all processing units.
- `async`: The most basic way of launching tasks asynchronously. Returns a `future<T>`.
- `future<T>`: Represents a value of type `T` that will be ready in the future. The value can be retrieved with `get` (blocking) and one can check if the value is ready with `is_ready` (non-blocking).
- `shared_future<T>`: Same as `future<T>` but can be copied (similar to `std::unique_ptr` vs `std::shared_ptr`).
- continuation: A function that is to be run after a previous task has run (represented by a future). `then` is a method of `future<T>` that takes a function to run next. Used to build up dataflow DAGs (directed acyclic graphs). `shared_future`s help you split up nodes in the DAG and functions like `when_all` help you join nodes in the DAG.

The following example is a collection of the most commonly used functionality in *HPX*:

```
#include <hpx/algorithm.hpp>
#include <hpx/future.hpp>
#include <hpx/init.hpp>

#include <iostream>
#include <random>
#include <vector>

void final_task(hpx::future<hpx::tuple<hpx::future<double>, hpx::future<void>>>)
{
    std::cout << "in final_task" << std::endl;
}

int hpx_main()
{
    // A function can be launched asynchronously. The program will not block
    // here until the result is available.
    hpx::future<int> f = hpx::async([]() { return 42; });
    std::cout << "Just launched a task!" << std::endl;

    // Use get to retrieve the value from the future. This will block this task
    // until the future is ready, but the HPX runtime will schedule other tasks
    // if there are tasks available.
    std::cout << "f contains " << f.get() << std::endl;
```

(continues on next page)

(continued from previous page)

```
    // Let's launch another task.
    hpx::future<double> g = hpx::async([]() { return 3.14; });

    // Tasks can be chained using the then method. The continuation takes the
    // future as an argument.
    hpx::future<double> result = g.then([](hpx::future<double>&& gg) {
        // This function will be called once g is ready. gg is g moved
        // into the continuation.
        return gg.get() * 42.0 * 42.0;
    });

    // You can check if a future is ready with the is_ready method.
    std::cout << "Result is ready? " << result.is_ready() << std::endl;

    // You can launch other work in the meantime. Let's sort a vector.
    std::vector<int> v(1000000);

    // We fill the vector synchronously and sequentially.
    hpx::generate(hpx::execution::seq, std::begin(v), std::end(v), &std::rand);

    // We can launch the sort in parallel and asynchronously.
    hpx::future<void> done_sorting =
        hpx::sort(hpx::execution::par(          // In parallel.
                      hpx::execution::task),    // Asynchronously.
            std::begin(v), std::end(v));

    // We launch the final task when the vector has been sorted and result is
    // ready using when_all.
    auto all = hpx::when_all(result, done_sorting).then(&final_task);

    // We can wait for all to be ready.
    all.wait();

    // all must be ready at this point because we waited for it to be ready.
    std::cout << (all.is_ready() ? "all is ready!" : "all is not ready...")
              << std::endl;

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

Try copying the contents to your `main.cpp` file and look at the output. It can be a good idea to go through the program step by step with a debugger. You can also try changing the types or adding new arguments to functions to make sure you can get the types to match. The type of the `then` method can be especially tricky to get right (the continuation needs to take the future as an argument).

> **Note**
>
> *HPX* programs accept command line arguments. The most important one is `--hpx:threads=N` to set the number of OS threads used by *HPX*. *HPX* uses one thread per core by default. Play around with the example above and see what difference the number of threads makes on the `sort` function. See *Launching and configuring HPX applications* for more details on how and what options you can pass to *HPX*.

> **Tip**
>
> The example above used the construction `hpx::when_all(...).then(...)`. For convenience and performance it is a good idea to replace uses of `hpx::when_all(...).then(...)` with `dataflow`. See *Dataflow* for more details on `dataflow`.

> **Tip**
>
> If possible, try to use the provided parallel algorithms instead of writing your own implementation. This can save you time and the resulting program is often faster.

2.1.4 Next steps

If you haven't done so already, reading the *Terminology* section will help you get familiar with the terms used in *HPX*.

The *Examples* section contains small, self-contained walkthroughs of example *HPX* programs. The *Local to remote* example is a thorough, realistic example starting from a single node implementation and going stepwise to a distributed implementation.

The *Manual* contains detailed information on writing, building and running *HPX* applications.

2.2 Tutorials

This section provides structured, video-based learning resources for *HPX*. The tutorials complement the reference documentation with guided, example-driven explanations of core concepts and advanced features.

Each tutorial introduces the relevant concepts and then applies them step by step through practical code examples. The focus is on demonstrating how to design, implement, and reason about parallel and distributed applications using *HPX*. While the main documentation emphasizes API descriptions and detailed reference material, the tutorial series adopts a practical, code-oriented approach.

The tutorials are intended for a broad audience: from beginners setting up HPX for the first time to advanced users exploring performance tuning, custom executors, and SIMD vectorization. Together, they form a structured learning path that lowers the entry barrier while progressively introducing more advanced features.

The complete video series is available on YouTube:

HPX Tutorial Playlist[11]

The code is available on Github:

HPX Tutorial Code <https://github.com/STEllAR-GROUP/HPX_Tutorials_Code>

[11] https://www.youtube.com/watch?v=OZWTmrlWUF0&list=PL7vEgTL3FalZkvNqssEP9-tXQ5rEwZy2l&index=1

2.2.1 Available Modules

- **Introduction to |hpx|**
  Foundational overview of *HPX*, including its architecture, design principles, and key capabilities in the context of high-performance computing.
- **Building |hpx| on Windows/Unix**
  Step-by-step guidance on installing *HPX* and setting up the environment based on your operating system.
- **Running |hpx| applications**
  Demonstation on how to build and run a simple Hello World example using *HPX*.
- **Algorithms in |hpx|**
  Overview of the parallel algorithms provided by *HPX* and explanation on how execution policies unlock high-performance C++ computing.
- **Vectorization and SIMD in |hpx|**
  Introduction to data-parallel programming, SIMD execution policies, and vectorization techniques relevant to modern C++ and HPC workloads.
- **Futures and Asynchronous Programming**
  Explanation of the asynchronous programming model in *HPX*, including futures, *async*, and dataflow-based execution patterns.
- **Performance Analysis and Optimization**
  Guidance on profiling *HPX* applications, analyzing performance counters, identifying bottlenecks, and applying optimization strategies.
- **Task Scheduling and Custom Executors**
  Detailed discussion of the execution model in *HPX*, built-in executors, and mechanisms for defining custom execution strategies.
- **Migration Guides**
  Best practices and recommendations for transitioning from other HPC frameworks to *HPX*.
- **HPX in Practice**
  Examples of open-source libraries and applications using *HPX*, illustrating real-world usage patterns and ecosystem integration.

2.3 Examples

The following sections analyze some examples to help you get familiar with the *HPX* style of programming. We start off with simple examples that utilize basic *HPX* elements and then begin to expose the reader to the more complex and powerful *HPX* concepts. Section *Building tests and examples* shows how you can build the examples.

2.3.1 Asynchronous execution

The Fibonacci sequence is a sequence of numbers starting with 0 and 1 where every subsequent number is the sum of the previous two numbers. In this example, we will use *HPX* to calculate the value of the n-th element of the Fibonacci sequence. In order to compute this problem in parallel, we will use a facility known as a future.

As shown in the Fig. **??** below, a future encapsulates a delayed computation. It acts as a proxy for a result initially not known, most of the time because the computation of the result has not completed yet. The future synchronizes the access of this value by optionally suspending any *HPX*-threads requesting the result until the value is available. When a future is created, it spawns a new *HPX*-thread (either remotely with a *parcel* or locally by placing it into the thread queue) which, when run, will execute the function associated with the future. The arguments of the function are bound when the future is created.

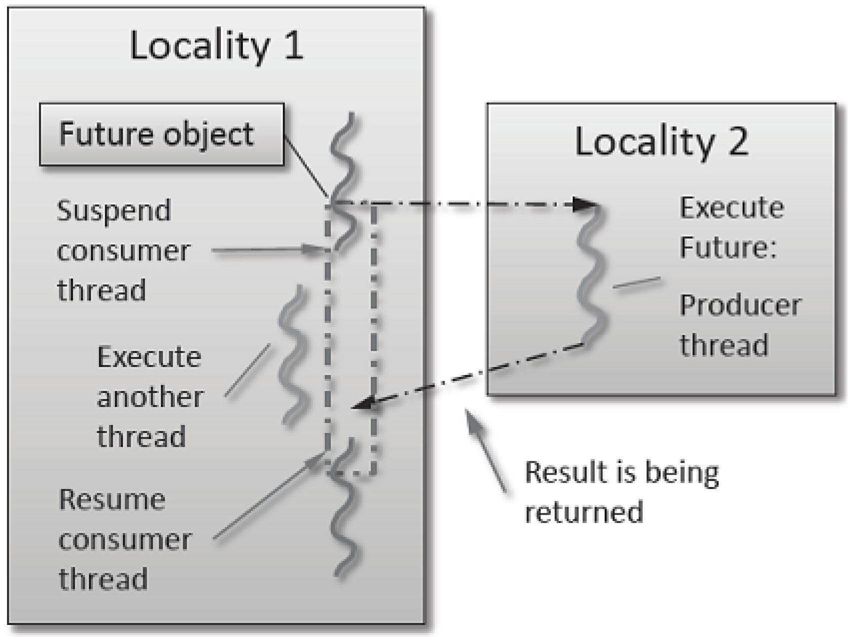

Fig. 2.1: Schematic of a future execution.

Once the function has finished executing, a write operation is performed on the future. The write operation marks the future as completed, and optionally stores data returned by the function. When the result of the delayed computation is needed, a read operation is performed on the future. If the future's function hasn't completed when a read operation is performed on it, the reader *HPX*-thread is suspended until the future is ready. The future facility allows *HPX* to schedule work early in a program so that when the function value is needed it will already be calculated and available. We use this property in our Fibonacci example below to enable its parallel execution.

Setup

The source code for this example can be found here: `fibonacci_local.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.fibonacci_local
```

To run the program type:

```
$ ./bin/fibonacci_local
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.002430 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the `--n-value` option. Additionally you can use the `--hpx:threads` option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
$ ./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.062854 [s]
```

Walkthrough

Now that you have compiled and run the code, let's look at how the code works. Since this code is written in C++, we will begin with the `main()` function. Here you can see that in *HPX*, `main()` is only used to initialize the runtime system. It is important to note that application-specific command line options are defined here. *HPX* uses Boost.Program_options[12] for command line processing. You can see that our programs `--n-value` option is set by calling the `add_options()` method on an instance of `hpx::program_options::options_description`. The default value of the variable is set to 10. This is why when we ran the program for the first time without using the `--n-value` option the program returned the 10th value of the Fibonacci sequence. The constructor argument of the description is the text that appears when a user uses the `--hpx:help` option to see what command line options are available. `HPX_APPLICATION_STRING` is a macro that expands to a string constant containing the name of the *HPX* application currently being compiled.

In *HPX* `main()` is used to initialize the runtime system and pass the command line arguments to the program. If you wish to add command line options to your program you would add them here using the instance of the Boost class `options_description`, and invoking the public member function `.add_options()` (see Boost Documentation[13] for more details). *hpx::init* calls `hpx_main()` after setting up *HPX*, which is where the logic of our program is encoded.

```
int main(int argc, char* argv[])
{
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline(
        "Usage: " HPX_APPLICATION_STRING " [options]");

    // clang-format off
    desc_commandline.add_options()
        ("n-value",
            hpx::program_options::value<std::uint64_t>()->default_value(10),
            "n value for the Fibonacci function")
        ;
    // clang-format on

    // Initialize and run HPX
    hpx::local::init_params init_args;
    init_args.desc_cmdline = desc_commandline;

    return hpx::local::init(hpx_main, argc, argv, init_args);
}
```

The *hpx::init* function in `main()` starts the runtime system, and invokes `hpx_main()` as the first *HPX*-thread. Below we can see that the basic program is simple. The command line option `--n-value` is read in, a timer (*hpx::chrono::high_resolution_timer*) is set up to record the time it takes to do the computation, the `fibonacci` function is invoked synchronously, and the answer is printed out.

[12] https://www.boost.org/doc/html/program_options.html
[13] https://www.boost.org/doc/

```
int hpx_main(hpx::program_options::variables_map& vm)
{
    hpx::threads::add_scheduler_mode(
        hpx::threads::policies::scheduler_mode::fast_idle_mode);

    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    {
        // Keep track of the time required to execute.
        hpx::chrono::high_resolution_timer t;

        std::uint64_t r = fibonacci(n);

        char const* fmt = "fibonacci({1}) == {2}\nelapsed time: {3} [s]\n";
        hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
    }

    return hpx::local::finalize();    // Handles HPX shutdown
}
```

The `fibonacci` function itself is synchronous as the work done inside is asynchronous. To understand what is happening we have to look inside the `fibonacci` function:

```
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    hpx::future<std::uint64_t> n1 = hpx::async(fibonacci, n - 1);
    std::uint64_t n2 = fibonacci(n - 2);

    return n1.get() + n2;    // wait for the Future to return their values
}
```

This block of code looks similar to regular C++ code. First, `if (n < 2)`, meaning n is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If n is larger than 1 we spawn two new tasks whose results are contained in `n1` and `n2`. This is done using *hpx::async* which takes as arguments a function (function pointer, object or lambda) and the arguments to the function. Instead of returning a `std::uint64_t` like `fibonacci` does, `hpx::async` returns a future of a `std::uint64_t`, i.e. `hpx::future<std::uint64_t>`. Each of these futures represents an asynchronous, recursive call to `fibonacci`. After we've created the futures, we wait for both of them to finish computing, we add them together, and return that value as our result. We get the values from the futures using the `get` method. The recursive call tree will continue until n is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the n-th value of the Fibonacci sequence.

Note that calling `get` potentially blocks the calling *HPX*-thread, and lets other *HPX*-threads run in the meantime. There are, however, more efficient ways of doing this. `examples/quickstart/fibonacci_futures.cpp` contains many more variations of locally computing the Fibonacci numbers, where each method makes different tradeoffs in where asynchrony and parallelism is applied. To get started, however, the method above is sufficient and optimizations can be applied once you are more familiar with *HPX*. The example *Dataflow* presents dataflow, which is a way to more efficiently chain together multiple tasks.

2.3.2 Parallel algorithms

This program will perform a matrix multiplication in parallel. The output will look something like this:

```
Matrix A is :
4 9 6
1 9 8

Matrix B is :
4 9
6 1
9 8

Resultant Matrix is :
124 93
130 82
```

Setup

The source code for this example can be found here: `matrix_multiplication.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.matrix_multiplication
```

To run the program type:

```
$ ./bin/matrix_multiplication
```

or:

```
$ ./bin/matrix_multiplication --n 2 --m 3 --k 2 --s 100 --l 0 --u 10
```

where the first matrix is *n* x *m* and the second *m* x *k*, s is the seed for creating the random values of the matrices and the range of these values is [l,u]

This should print:

```
Matrix A is :
4 9 6
1 9 8

Matrix B is :
4 9
6 1
9 8

Resultant Matrix is :
124 93
130 82
```

Notice that the numbers may be different because of the random initialization of the matrices.

Walkthrough

Now that you have compiled and run the code, let's look at how the code works.

First, `main()` is used to initialize the runtime system and pass the command line arguments to the program. `hpx::init` calls `hpx_main()` after setting up HPX, which is where our program is implemented.

```
int main(int argc, char* argv[])
{
    using namespace hpx::program_options;
    options_description cmdline("usage: " HPX_APPLICATION_STRING " [options]");
    // clang-format off
    cmdline.add_options()
        ("n",
        hpx::program_options::value<std::size_t>()->default_value(2),
        "Number of rows of first matrix")
        ("m",
        hpx::program_options::value<std::size_t>()->default_value(3),
        "Number of columns of first matrix (equal to the number of rows of "
        "second matrix)")
        ("k",
        hpx::program_options::value<std::size_t>()->default_value(2),
        "Number of columns of second matrix")
        ("seed,s",
        hpx::program_options::value<unsigned int>(),
        "The random number generator seed to use for this run")
        ("l",
        hpx::program_options::value<int>()->default_value(0),
        "Lower limit of range of values")
        ("u",
        hpx::program_options::value<int>()->default_value(10),
        "Upper limit of range of values");
    // clang-format on
    hpx::local::init_params init_args;
    init_args.desc_cmdline = cmdline;

    return hpx::local::init(hpx_main, argc, argv, init_args);
}
```

Proceeding to the `hpx_main()` function, we can see that matrix multiplication can be done very easily.

```
int hpx_main(hpx::program_options::variables_map& vm)
{
    using element_type = int;

    // Define matrix sizes
    std::size_t const rowsA = vm["n"].as<std::size_t>();
    std::size_t const colsA = vm["m"].as<std::size_t>();
    std::size_t const rowsB = colsA;
    std::size_t const colsB = vm["k"].as<std::size_t>();
    std::size_t const rowsR = rowsA;
    std::size_t const colsR = colsB;

    // Initialize matrices A and B
```

(continues on next page)

(continued from previous page)

```
    std::vector<int> A(rowsA * colsA);
    std::vector<int> B(rowsB * colsB);
    std::vector<int> R(rowsR * colsR);

    // Define seed
    unsigned int seed = std::random_device{}();
    if (vm.count("seed"))
        seed = vm["seed"].as<unsigned int>();

    gen.seed(seed);
    std::cout << "using seed: " << seed << std::endl;

    // Define range of values
    int const lower = vm["l"].as<int>();
    int const upper = vm["u"].as<int>();

    // Matrices have random values in the range [lower, upper]
    std::uniform_int_distribution<element_type> dis(lower, upper);
    auto generator = std::bind(dis, gen);
    hpx::ranges::generate(A, generator);
    hpx::ranges::generate(B, generator);

    // Perform matrix multiplication
    hpx::experimental::for_loop(hpx::execution::par, 0, rowsA, [&](auto i) {
        hpx::experimental::for_loop(0, colsB, [&](auto j) {
            R[i * colsR + j] = 0;
            hpx::experimental::for_loop(0, rowsB, [&](auto k) {
                R[i * colsR + j] += A[i * colsA + k] * B[k * colsB + j];
            });
        });
    });

    // Print all 3 matrices
    print_matrix(A, rowsA, colsA, "A");
    print_matrix(B, rowsB, colsB, "B");
    print_matrix(R, rowsR, colsR, "R");

    return hpx::local::finalize();
}
```

First, the dimensions of the matrices are defined. If they were not given as command-line arguments, their default values are *2* x *3* for the first matrix and *3* x *2* for the second. We use standard vectors to define the matrices to be multiplied as well as the resultant matrix.

To give some random initial values to our matrices, we use std::uniform_int_distribution[14]. Then, `std::bind()` is used along with `hpx::ranges::generate()` to yield two matrices A and B, which contain values in the range of [0, 10] or in the range defined by the user at the command-line arguments. The seed to generate the values can also be defined by the user.

The next step is to perform the matrix multiplication in parallel. This can be done by just using an *hpx::experimental::for_loop* combined with a parallel execution policy `hpx::execution::par` as the outer loop of the multiplication. Note that the execution of *hpx::experimental::for_loop* without specifying an execution policy is

[14] https://en.cppreference.com/w/cpp/numeric/random/uniform_int_distribution

equivalent to specifying `hpx::execution::seq` as the execution policy.

Finally, the matrices A, B that are multiplied as well as the resultant matrix R are printed using the following function.

```
void print_matrix(std::vector<int> const& M, std::size_t rows, std::size_t cols,
    char const* message)
{
    std::cout << "\nMatrix " << message << " is:" << std::endl;
    for (std::size_t i = 0; i < rows; i++)
    {
        for (std::size_t j = 0; j < cols; j++)
            std::cout << M[i * cols + j] << " ";
        std::cout << "\n";
    }
}
```

2.3.3 Asynchronous execution with actions

This example extends the *previous example* by introducing *actions*: functions that can be run remotely. In this example, however, we will still only run the action locally. The mechanism to execute *actions* stays the same: *hpx::async*. Later examples will demonstrate running actions on remote *localities* (e.g. *Remote execution with actions*).

Setup

The source code for this example can be found here: `fibonacci.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.fibonacci
```

To run the program type:

```
$ ./bin/fibonacci
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.00186288 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the `--n-value` option. Additionally you can use the `--hpx:threads` option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
$ ./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.233827 [s]
```

Walkthrough

The code needed to initialize the *HPX* runtime is the same as in the *previous example*:

```
int main(int argc, char* argv[])
{
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline(
        "Usage: " HPX_APPLICATION_STRING " [options]");

    desc_commandline.add_options()("n-value",
        hpx::program_options::value<std::uint64_t>()->default_value(10),
        "n value for the Fibonacci function");

    // Initialize and run HPX
    hpx::init_params init_args;
    init_args.desc_cmdline = desc_commandline;

    return hpx::init(argc, argv, init_args);
}
```

The *hpx::init* function in `main()` starts the runtime system, and invokes `hpx_main()` as the first *HPX*-thread. The command line option `--n-value` is read in, a timer (*hpx::chrono::high_resolution_timer*) is set up to record the time it takes to do the computation, the `fibonacci` *action* is invoked synchronously, and the answer is printed out.

```
int hpx_main(hpx::program_options::variables_map& vm)
{
    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    {
        // Keep track of the time required to execute.
        hpx::chrono::high_resolution_timer t;

        // Wait for fib() to return the value
        fibonacci_action fib;
        std::uint64_t r = fib(hpx::find_here(), n);

        char const* fmt = "fibonacci({1}) == {2}\nelapsed time: {3} [s]\n";
        hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
    }

    return hpx::finalize();    // Handles HPX shutdown
}
```

Upon a closer look we see that we've created a `std::uint64_t` to store the result of invoking our `fibonacci_action fib`. This *action* will launch synchronously (as the work done inside of the *action* will be asynchronous itself) and return the result of the Fibonacci sequence. But wait, what is an *action*? And what is this `fibonacci_action`? For starters, an *action* is a wrapper for a function. By wrapping functions, *HPX* can send packets of work to different processing units. These vehicles allow users to calculate work now, later, or on certain nodes. The first argument to our *action* is the location where the *action* should be run. In this case, we just want to run the *action* on the machine that we are currently on, so we use *`hpx::find_here`*. To further understand this we turn to the code to find where `fibonacci_action` was defined:

```
// forward declaration of the Fibonacci function
std::uint64_t fibonacci(std::uint64_t n);

// This is to generate the required boilerplate we need for the remote
// invocation to work.
HPX_PLAIN_ACTION(fibonacci, fibonacci_action)
```

A plain *action* is the most basic form of *action*. Plain *action*s wrap simple global functions which are not associated with any particular object (we will discuss other types of *action*s in *Components and actions*). In this block of code the function `fibonacci()` is declared. After the declaration, the function is wrapped in an *action* in the declaration *HPX_PLAIN_ACTION*. This function takes two arguments: the name of the function that is to be wrapped and the name of the *action* that you are creating.

This picture should now start making sense. The function `fibonacci()` is wrapped in an *action* `fibonacci_action`, which was run synchronously but created asynchronous work, then returns a `std::uint64_t` representing the result of the function `fibonacci()`. Now, let's look at the function `fibonacci()`:

```
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // We restrict ourselves to execute the Fibonacci function locally.
    hpx::id_type const locality_id = hpx::find_here();

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.

    fibonacci_action fib;
    hpx::future<std::uint64_t> n1 = hpx::async(fib, locality_id, n - 1);
    hpx::future<std::uint64_t> n2 = hpx::async(fib, locality_id, n - 2);

    return n1.get() +
        n2.get();    // wait for the Futures to return their values
}
```

This block of code is much more straightforward and should look familiar from the *previous example*. First, `if (n < 2)`, meaning n is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If n is larger than 1 we spawn two tasks using *hpx::async*. Each of these futures represents an asynchronous, recursive call to `fibonacci`. As previously we wait for both futures to finish computing, get the results, add them together, and return that value as our result. The recursive call tree will continue until n is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the n-th value of the Fibonacci sequence.

2.3.4 Remote execution with actions

This program will print out a hello world message on every OS-thread on every *locality*. The output will look something like this:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 0 on locality 1
```

Setup

The source code for this example can be found here: `hello_world_distributed.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.hello_world_distributed
```

To run the program type:

```
$ ./bin/hello_world_distributed
```

This should print:

```
hello world from OS-thread 0 on locality 0
```

To use more OS-threads use the command line option `--hpx:threads` and type the number of threads that you wish to use. For example, typing:

```
$ ./bin/hello_world_distributed --hpx:threads 2
```

will yield:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
```

Notice how the ordering of the two print statements will change with subsequent runs. To run this program on multiple localities please see the section *How to use HPX applications with PBS*.

Walkthrough

Now that you have compiled and run the code, let's look at how the code works, beginning with `main()`:

```
// Here is the main entry point. By using the include 'hpx/hpx_main.hpp' HPX
// will invoke the plain old C-main() as its first HPX thread.
int main()
{
    // Get a list of all available localities.
    std::vector<hpx::id_type> localities = hpx::find_all_localities();

    // Reserve storage space for futures, one for each locality.
    std::vector<hpx::future<void>> futures;
```

(continues on next page)

(continued from previous page)

```
    futures.reserve(localities.size());

    for (hpx::id_type const& node : localities)
    {
        // Asynchronously start a new task. The task is encapsulated in a
        // future, which we can query to determine if the task has
        // completed.
        typedef hello_world_foreman_action action_type;
        futures.push_back(hpx::async<action_type>(node));
    }

    // The non-callback version of hpx::wait_all takes a single parameter,
    // a vector of futures to wait on. hpx::wait_all only returns when
    // all of the futures have finished.
    hpx::wait_all(futures);
    return 0;
}
```

In this excerpt of the code we again see the use of futures. This time the futures are stored in a vector so that they can easily be accessed. *hpx::wait_all* is a family of functions that wait on for an `std::vector<>` of futures to become ready. In this piece of code, we are using the synchronous version of *`hpx::wait_all`*, which takes one argument (the `std::vector<>` of futures to wait on). This function will not return until all the futures in the vector have been executed.

In *Asynchronous execution with actions* we used *`hpx::find_here`* to specify the target of our actions. Here, we instead use *`hpx::find_all_localities`*, which returns an `std::vector<>` containing the identifiers of all the machines in the system, including the one that we are on.

As in *Asynchronous execution with actions* our futures are set using *`hpx::async<>`*. The `hello_world_foreman_action` is declared here:

```
// Define the boilerplate code necessary for the function 'hello_world_foreman'
// to be invoked as an HPX action.
HPX_PLAIN_ACTION(hello_world_foreman, hello_world_foreman_action)
```

Another way of thinking about this wrapping technique is as follows: functions (the work to be done) are wrapped in actions, and actions can be executed locally or remotely (e.g. on another machine participating in the computation).

Now it is time to look at the `hello_world_foreman()` function which was wrapped in the action above:

```
void hello_world_foreman()
{
    // Get the number of worker OS-threads in use by this locality.
    std::size_t const os_threads = hpx::get_os_thread_count();

    // Populate a set with the OS-thread numbers of all OS-threads on this
    // locality. When the hello world message has been printed on a particular
    // OS-thread, we will remove it from the set.
    std::set<std::size_t> attendance;
    for (std::size_t os_thread = 0; os_thread < os_threads; ++os_thread)
        attendance.insert(os_thread);

    // As long as there are still elements in the set, we must keep scheduling
    // HPX-threads. Because HPX features work-stealing task schedulers, we have
```

(continues on next page)

(continued from previous page)

```
    // no way of enforcing which worker OS-thread will actually execute
    // each HPX-thread.
    while (!attendance.empty())
    {
        // Each iteration, we create a task for each element in the set of
        // OS-threads that have not said "Hello world". Each of these tasks
        // is encapsulated in a future.
        std::vector<hpx::future<std::size_t>> futures;
        futures.reserve(attendance.size());

        for (std::size_t worker : attendance)
        {
            // Asynchronously start a new task. The task is encapsulated in a
            // future that we can query to determine if the task has completed.
            //
            // We give the task a hint to run on a particular worker thread
            // (core) and suggest binding the scheduled thread to the given
            // core, but no guarantees are given by the scheduler that the task
            // will actually run on that worker thread. It will however try as
            // hard as possible to place the new task on the given worker
            // thread.
            hpx::execution::parallel_executor exec(
                hpx::threads::thread_priority::bound);

            hpx::threads::thread_schedule_hint hint(
                hpx::threads::thread_schedule_hint_mode::thread,
                static_cast<std::int16_t>(worker));

            // Annotate the created threads with the given thread name
            hpx::execution::experimental::annotating_executor annotating_exec(
                hpx::execution::experimental::with_hint(exec, hint),
                std::string("hello_world_worker#") + std::to_string(worker));

            futures.push_back(
                hpx::async(annotating_exec, hello_world_worker, worker));
        }

        // Wait for all of the futures to finish. The callback version of the
        // hpx::wait_each function takes two arguments: a vector of futures,
        // and a binary callback.  The callback takes two arguments; the first
        // is the index of the future in the vector, and the second is the
        // return value of the future. hpx::wait_each doesn't return until
        // all the futures in the vector have returned.
        hpx::spinlock mtx;
        hpx::wait_each(hpx::unwrapping([&](std::size_t t) {
            if (std::size_t(-1) != t)
            {
                std::lock_guard<hpx::spinlock> lk(mtx);
                attendance.erase(t);
            }
        }),
            futures);
```

(continues on next page)

(continued from previous page)

```
    }
}
```

Now, before we discuss `hello_world_foreman()`, let's talk about the *hpx::wait_each* function. The version of *hpx::wait_each* invokes a callback function provided by the user, supplying the callback function with the result of the future.

In `hello_world_foreman()`, an `std::set<>` called `attendance` keeps track of which OS-threads have printed out the hello world message. When the OS-thread prints out the statement, the future is marked as ready, and *hpx::wait_each* in `hello_world_foreman()`. If it is not executing on the correct OS-thread, it returns a value of -1, which causes `hello_world_foreman()` to leave the OS-thread id in `attendance`.

```
std::size_t hello_world_worker(std::size_t desired)
{
    // Returns the OS-thread number of the worker that is running this
    // HPX-thread.
    std::size_t current = hpx::get_worker_thread_num();
    if (current == desired)
    {
        // The HPX-thread has been run on the desired OS-thread.
        char const* msg = "hello world from OS-thread {1} on locality {2}\n";

        hpx::util::format_to(hpx::cout, msg, desired, hpx::get_locality_id())
            << std::flush;

        return desired;
    }

    // This HPX-thread has been run by the wrong OS-thread, make the foreman
    // try again by rescheduling it.
    return std::size_t(-1);
}
```

Because *HPX* features work stealing task schedulers, there is no way to guarantee that an action will be scheduled on a particular OS-thread. This is why we must use a guess-and-check approach.

2.3.5 Components and actions

The accumulator examples demonstrate the use of components. Components are C++ classes that expose methods as a type of *HPX* action. These actions are called component actions. There are three examples: - accumulator - template accumulator - template function accumulator

Components are globally named, meaning that a component action can be called remotely (e.g., from another machine). There are two accumulator examples in *HPX*.

In the *Asynchronous execution with actions* and the *Remote execution with actions*, we introduced plain actions, which wrapped global functions. The target of a plain action is an identifier which refers to a particular machine involved in the computation. For plain actions, the target is the machine where the action will be executed.

Component actions, however, do not target machines. Instead, they target component instances. The instance may live on the machine that we've invoked the component action from, or it may live on another machine.

The components in these examples expose three different functions:

- `reset()` - Resets the accumulator value to 0.

- `add(arg)` - Adds `arg` to the accumulators value.
- `query()` - Queries the value of the accumulator.

These examples create an instance of the (template or template function) accumulator, and then allow the user to enter commands at a prompt, which subsequently invoke actions on the accumulator instance.

Accumulator

Setup

The source code for this example can be found here: `accumulator_client.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.accumulators.accumulator
```

To run the program type:

```
$ ./bin/accumulator_client
```

Once the program starts running, it will print the following prompt and then wait for input. An example session is given below:

```
commands: reset, add [amount], query, help, quit
> add 5
> add 10
> query
15
> add 2
> query
17
> reset
> add 1
> query
1
> quit
```

Walkthrough

Now, let's take a look at the source code of the accumulator example. This example consists of two parts: an *HPX* component library (a library that exposes an *HPX* component) and a client application which uses the library. This walkthrough will cover the *HPX* component library. The code for the client application can be found here: `accumulator_client.cpp`.

An *HPX* component is represented by two C++ classes:

- **A server class** - The implementation of the component's functionality.
- **A client class** - A high-level interface that acts as a proxy for an instance of the component.

Typically, these two classes both have the same name, but the server class usually lives in different sub-namespaces (`server`). For example, the full names of the two classes in accumulator are:

- `examples::server::accumulator` (server class)

- `examples::accumulator` (client class)

The server class

The following code is from server/accumulator.hpp[15].

All *HPX* component server classes must inherit publicly from the *HPX* component base class: *hpx::components::component_base*

The accumulator component inherits from `hpx::components::locking_hook`. This allows the runtime system to ensure that all action invocations are serialized. That means that the system ensures that no two actions are invoked at the same time on a given component instance. This makes the component thread safe and no additional locking has to be implemented by the user. Moreover, an accumulator component is a component because it also inherits from *hpx::components::component_base* (the template argument passed to locking_hook is used as its base class). The following snippet shows the corresponding code:

```
    class accumulator
      : public hpx::components::locking_hook<
            hpx::components::component_base<accumulator>>
```

Our accumulator class will need a data member to store its value in, so let's declare a data member:

```
        argument_type value_;
```

The constructor for this class simply initializes `value_` to 0:

```
        accumulator()
          : value_(0)
        {
        }
```

Next, let's look at the three methods of this component that we will be exposing as component actions:

Here are the action types. These types wrap the methods we're exposing. The wrapping technique is very similar to the one used in the *Asynchronous execution with actions* and the *Remote execution with actions*:

```
        HPX_DEFINE_COMPONENT_ACTION(accumulator, reset)
        HPX_DEFINE_COMPONENT_ACTION(accumulator, add)
        HPX_DEFINE_COMPONENT_ACTION(accumulator, query)
```

The last piece of code in the server class header is the declaration of the action type registration code:

```
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::reset_action, accumulator_reset_action)

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::add_action, accumulator_add_action)

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::query_action, accumulator_query_action)
```

[15] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/server/accumulator.hpp

Note

The code above must be placed in the global namespace.

The rest of the registration code is in accumulator.cpp[16]

```
///////////////////////////////////////////////////////////////////////////////
// Add factory registration functionality.
HPX_REGISTER_COMPONENT_MODULE()

///////////////////////////////////////////////////////////////////////////////
typedef hpx::components::component<examples::server::accumulator>
    accumulator_type;

HPX_REGISTER_COMPONENT(accumulator_type, accumulator)

///////////////////////////////////////////////////////////////////////////////
// Serialization support for accumulator actions.
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::reset_action, accumulator_reset_action)
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::add_action, accumulator_add_action)
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::query_action, accumulator_query_action)
```

Note

The code above must be placed in the global namespace.

The client class

The following code is from accumulator.hpp[17]

The client class is the primary interface to a component instance. Client classes are used to create components:

```
// Create a component on this locality.
examples::accumulator c = hpx::new_<examples::accumulator>(hpx::find_here());
```

and to invoke component actions:

```
c.add(hpx::launch::apply, 4);
```

Clients, like servers, need to inherit from a base class, this time, *hpx::components::client_base*:

```
    class accumulator
      : public hpx::components::client_base<accumulator, server::accumulator>
```

For readability, we typedef the base class like so:

[16] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/accumulator.cpp
[17] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/accumulator.hpp

```
    typedef hpx::components::client_base<accumulator, server::accumulator>
        base_type;
```

Here are examples of how to expose actions through a client class:

There are a few different ways of invoking actions:

- **Non-blocking**: For actions that don't have return types, or when we do not care about the result of an action, we can invoke the action using fire-and-forget semantics. This means that once we have asked *HPX* to compute the action, we forget about it completely and continue with our computation. We use *hpx::post* to invoke an action in a non-blocking fashion.

```
    void reset(hpx::launch::apply_policy)
    {
        HPX_ASSERT(this->get_id());

        typedef server::accumulator::reset_action action_type;
        hpx::post(action_type(), this->get_id());
    }
```

- **Asynchronous**: Futures, as demonstrated in *Asynchronous execution*, *Asynchronous execution with actions*, and the *Remote execution with actions*, enable asynchronous action invocation. Here's an example from the accumulator client class:

```
    hpx::future<argument_type> query(hpx::launch::async_policy)
    {
        HPX_ASSERT(this->get_id());

        typedef server::accumulator::query_action action_type;
        return hpx::async(action_type(), this->get_id());
    }
```

- **Synchronous**: To invoke an action in a fully synchronous manner, we can simply call *hpx::sync* which is semantically equivalent to *hpx::async*`().get()` (i.e., create a future and immediately wait on it to be ready). Here's an example from the accumulator client class:

```
    void add(argument_type arg)
    {
        HPX_ASSERT(this->get_id());

        typedef server::accumulator::add_action action_type;
        action_type()(this->get_id(), arg);
    }
```

Note that `this->get_id()` references a data member of the *hpx::components::client_base* base class which identifies the server accumulator instance.

`hpx::id_type` is a type which represents a global identifier in *HPX*. This type specifies the target of an action. This is the type that is returned by *`hpx::find_here`* in which case it represents the *locality* the code is running on.

Template accumulator

Walkthrough

The server class

The following code is from server/template_accumulator.hpp[18].

Similarly to the accumulator example, the component server class inherits publicly from *hpx::components::component_base* and from `hpx::components::locking_hook` ensuring thread-safe method invocations.

```
template <typename T>
class template_accumulator
  : public hpx::components::locking_hook<
        hpx::components::component_base<template_accumulator<T>>>
```

The body of the template accumulator class remains mainly the same as the accumulator with the difference that it uses templates in the data types.

```
        typedef T argument_type;

        template_accumulator()
          : value_(0)
        {
        }

        ///////////////////////////////////////////////////////////////////////
        // Exposed functionality of this component.

        /// Reset the components value to 0.
        void reset()
        {
            //  set value_ to 0.
            value_ = 0;
        }

        /// Add the given number to the accumulator.
        void add(argument_type arg)
        {
            //  add value_ to arg, and store the result in value_.
            value_ += arg;
        }

        /// Return the current value to the caller.
        argument_type query() const
        {
            // Get the value of value_.
            return value_;
        }
```

(continues on next page)

18 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/server/template_accumulator.hpp

(continued from previous page)

```
    ///////////////////////////////////////////////////////////////////////
    // Each of the exposed functions needs to be encapsulated into an
    // action type, generating all required boilerplate code for threads,
    // serialization, etc.
    HPX_DEFINE_COMPONENT_ACTION(template_accumulator, reset)
    HPX_DEFINE_COMPONENT_ACTION(template_accumulator, add)
    HPX_DEFINE_COMPONENT_ACTION(template_accumulator, query)
```

The last piece of code in the server class header is the declaration of the action type registration code. *REGISTER_TEMPLATE_ACCUMULATOR_DECLARATION(type)* declares actions for the specified type, while *REGISTER_TEMPLATE_ACCUMULATOR(type)* registers the actions and the component for the specified type, using macros to handle boilerplate code.

```
#define REGISTER_TEMPLATE_ACCUMULATOR_DECLARATION(type)                      \
    HPX_REGISTER_ACTION_DECLARATION(                                         \
        examples::server::template_accumulator<type>::reset_action,          \
        HPX_PP_CAT(__template_accumulator_reset_action_, type))              \
                                                                             \
    HPX_REGISTER_ACTION_DECLARATION(                                         \
        examples::server::template_accumulator<type>::add_action,            \
        HPX_PP_CAT(__template_accumulator_add_action_, type))                \
                                                                             \
    HPX_REGISTER_ACTION_DECLARATION(                                         \
        examples::server::template_accumulator<type>::query_action,          \
        HPX_PP_CAT(__template_accumulator_query_action_, type))              \
    /**/

#define REGISTER_TEMPLATE_ACCUMULATOR(type)                                  \
    HPX_REGISTER_ACTION(                                                     \
        examples::server::template_accumulator<type>::reset_action,          \
        HPX_PP_CAT(__template_accumulator_reset_action_, type))              \
                                                                             \
    HPX_REGISTER_ACTION(                                                     \
        examples::server::template_accumulator<type>::add_action,            \
        HPX_PP_CAT(__template_accumulator_add_action_, type))                \
                                                                             \
    HPX_REGISTER_ACTION(                                                     \
        examples::server::template_accumulator<type>::query_action,          \
        HPX_PP_CAT(__template_accumulator_query_action_, type))              \
                                                                             \
    typedef ::hpx::components::component<                                    \
        examples::server::template_accumulator<type>>                        \
        HPX_PP_CAT(__template_accumulator_, type);                           \
    HPX_REGISTER_COMPONENT(HPX_PP_CAT(__template_accumulator_, type))        \
    /**/
```

Note

The code above must be placed in the global namespace.

Finally, *HPX_REGISTER_COMPONENT_MODULE()* in file server/template_accumulator.cpp[19] adds the factory registration functionality.

The client class

The client class of the template accumulator can be found in template_accumulator.hpp[20] and is very similar to the client class of the accumulator with the only difference that it uses templates and hence can work with different types.

Template function accumulator

Walkthrough

The server class

The following code is from server/template_function_accumulator.hpp[21].

The component server class inherits publicly from *hpx::components::component_base*.

```
class template_function_accumulator
  : public hpx::components::component_base<template_function_accumulator>
```

typedef hpx::spinlock mutex_type defines a *mutex_type* as *hpx::spinlock* for thread safety, while the code that follows exposes the functionality of this component.

```
        ///////////////////////////////////////////////////////////////////////
        // Exposed functionality of this component.

        /// Reset the value to 0.
        void reset()
        {
            // Atomically set value_ to 0.
            std::lock_guard<mutex_type> l(mtx_);
            value_ = 0;
        }

        /// Add the given number to the accumulator.
        template <typename T>
        void add(T arg)
        {
            // Atomically add value_ to arg, and store the result in value_.
            std::lock_guard<mutex_type> l(mtx_);
            value_ += static_cast<double>(arg);
        }

        /// Return the current value to the caller.
        double query() const
```

(continues on next page)

[19] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/server/template_accumulator.cpp

[20] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/template_accumulator.hpp

[21] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/server/template_function_accumulator.hpp

(continued from previous page)

```
        {
            // Get the value of value_.
            std::lock_guard<mutex_type> l(mtx_);
            return value_;
        }
```

- *reset()*: Resets the accumulator value to *0* in a thread-safe manner using *std::lock_guard*.
- *add()*: Adds a value to the accumulator, allowing any type *T* that can be cast to double.
- *query()*: Returns the current value of the accumulator in a thread-safe manner.

To define the actions for *reset()* and *query()* we can use the macro *HPX_DEFINE_COMPONENT_ACTION*. However, actions with template arguments require special type definitions. Therefore, we use *make_action()* to define *add()*.

```
        ///////////////////////////////////////////////////////////////////////
        // Each of the exposed functions needs to be encapsulated into an
        // action type, generating all required boilerplate code for threads,
        // serialization, etc.

        HPX_DEFINE_COMPONENT_ACTION(template_function_accumulator, reset)
        HPX_DEFINE_COMPONENT_ACTION(template_function_accumulator, query)

        // Actions with template arguments (see add<>() above) require special
        // type definitions. The simplest way to define such an action type is
        // by deriving from the HPX facility make_action.
        template <typename T>
        struct add_action
          : hpx::actions::make_action<void (template_function_accumulator::*)(
                                          T),
                &template_function_accumulator::template add<T>,
                add_action<T>>::type
        {
        };
```

The last piece of code in the server class header is the action registration:

```
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::template_function_accumulator::reset_action,
    managed_accumulator_reset_action)

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::template_function_accumulator::query_action,
    managed_accumulator_query_action)
```

Note

The code above must be placed in the global namespace.

The rest of the registration code is in accumulator.cpp[22]

[22] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/accumulator.cpp

```
///////////////////////////////////////////////////////////////////////////////
// Add factory registration functionality.
HPX_REGISTER_COMPONENT_MODULE()

///////////////////////////////////////////////////////////////////////////////
typedef hpx::components::component<
    examples::server::template_function_accumulator>
    accumulator_type;

HPX_REGISTER_COMPONENT(accumulator_type, template_function_accumulator)

///////////////////////////////////////////////////////////////////////////////
// Serialization support for managed_accumulator actions.
HPX_REGISTER_ACTION(accumulator_type::wrapped_type::reset_action,
    managed_accumulator_reset_action)
HPX_REGISTER_ACTION(accumulator_type::wrapped_type::query_action,
    managed_accumulator_query_action)
```

Note

The code above must be placed in the global namespace.

The client class

The client class of the template accumulator can be found in template_function_accumulator.hpp[23] and is very similar to the client class of the accumulator with the only difference that it uses templates and hence can work with different types.

2.3.6 Dataflow

HPX provides its users with several different tools to simply express parallel concepts. One of these tools is a *local control object* (*LCO*) called dataflow. An *LCO* is a type of component that can spawn a new thread when triggered. They are also distinguished from other components by a standard interface that allow users to understand and use them easily. A Dataflow, being an *LCO*, is triggered when the values it depends on become available. For instance, if you have a calculation X that depends on the results of three other calculations, you could set up a dataflow that would begin the calculation X as soon as the other three calculations have returned their values. Dataflows are set up to depend on other dataflows. It is this property that makes dataflow a powerful parallelization tool. If you understand the dependencies of your calculation, you can devise a simple algorithm that sets up a dependency tree to be executed. In this example, we calculate compound interest. To calculate compound interest, one must calculate the interest made in each compound period, and then add that interest back to the principal before calculating the interest made in the next period. A practical person would, of course, use the formula for compound interest:

$$F = P(1 + i)^n$$

where F is the future value, P is the principal value, i is the interest rate, and n is the number of compound periods.

However, for the sake of this example, we have chosen to manually calculate the future value by iterating:

$$I = Pi$$

[23] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/examples/accumulators/template_function_accumulator.hpp

and

$$P = P + I$$

Setup

The source code for this example can be found here: `interest_calculator.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.interest_calculator
```

To run the program type:

```
$ ./bin/interest_calculator --principal 100 --rate 5 --cp 6 --time 36
Final amount: 134.01
Amount made: 34.0096
```

Walkthrough

Let us begin with main. Here we can see that we again are using Boost.Program_options to set our command line variables (see *Asynchronous execution with actions* for more details). These options set the principal, rate, compound period, and time. It is important to note that the units of time for `cp` and `time` must be the same.

```
int main(int argc, char** argv)
{
    options_description cmdline("Usage: " HPX_APPLICATION_STRING " [options]");

    cmdline.add_options()("principal", value<double>()->default_value(1000),
        "The principal [$]")("rate", value<double>()->default_value(7),
        "The interest rate [%]")("cp", value<int>()->default_value(12),
        "The compound period [months]")("time",
        value<int>()->default_value(12 * 30),
        "The time money is invested [months]");

    hpx::init_params init_args;
    init_args.desc_cmdline = cmdline;

    return hpx::init(argc, argv, init_args);
}
```

Next we look at hpx_main.

```
int hpx_main(variables_map& vm)
{
    {
        using hpx::dataflow;
        using hpx::make_ready_future;
        using hpx::shared_future;
        using hpx::unwrapping;
        hpx::id_type here = hpx::find_here();
```

(continues on next page)

(continued from previous page)

```
        double init_principal =
            vm["principal"].as<double>();              //Initial principal
        double init_rate = vm["rate"].as<double>();    //Interest rate
        int cp = vm["cp"].as<int>();      //Length of a compound period
        int t = vm["time"].as<int>();     //Length of time money is invested

        init_rate /= 100;     //Rate is a % and must be converted
        t /= cp;     //Determine how many times to iterate interest calculation:
        //How many full compound periods can fit in the time invested

        // In non-dataflow terms the implemented algorithm would look like:
        //
        // int t = 5;     // number of time periods to use
        // double principal = init_principal;
        // double rate = init_rate;
        //
        // for (int i = 0; i < t; ++i)
        // {
        //     double interest = calc(principal, rate);
        //     principal = add(principal, interest);
        // }
        //
        // Please note the similarity with the code below!

        shared_future<double> principal = make_ready_future(init_principal);
        shared_future<double> rate = make_ready_future(init_rate);

        for (int i = 0; i < t; ++i)
        {
            shared_future<double> interest =
                dataflow(unwrapping(calc), principal, rate);
            principal = dataflow(unwrapping(add), principal, interest);
        }

        // wait for the dataflow execution graph to be finished calculating our
        // overall interest
        double result = principal.get();

        std::cout << "Final amount: " << result << std::endl;
        std::cout << "Amount made: " << result - init_principal << std::endl;
    }

    return hpx::finalize();
}
```

Here we find our command line variables read in, the rate is converted from a percent to a decimal, the number of calculation iterations is determined, and then our shared_futures are set up. Notice that we first place our principal and rate into shares futures by passing the variables `init_principal` and `init_rate` using *hpx::make_ready_future*.

In this way *hpx::shared_future*`<double>` `principal` and `rate` will be initialized to `init_principal` and `init_rate` when *hpx::make_ready_future*`<double>` returns a future containing those initial values. These shared futures then enter the for loop and are passed to `interest`. Next `principal` and `interest` are passed to the reassignment of `principal` using a *hpx::dataflow*. A dataflow will first wait for its arguments to be ready before launching any callbacks, so add in this case will not begin until both principal and interest are ready. This loop continues for each compound period that must be calculated. To see how interest and principal are calculated in the loop, let us look at calc_action and add_action:

```
// Calculate interest for one period
double calc(double principal, double rate)
{
    return principal * rate;
}

///////////////////////////////////////////////////////////////////////////////
// Add the amount made to the principal
double add(double principal, double interest)
{
    return principal + interest;
}
```

After the shared future dependencies have been defined in hpx_main, we see the following statement:

```
double result = principal.get();
```

This statement calls hpx::future::get on the shared future principal which had its value calculated by our for loop. The program will wait here until the entire dataflow tree has been calculated and the value assigned to result. The program then prints out the final value of the investment and the amount of interest made by subtracting the final value of the investment from the initial value of the investment.

2.3.7 Local to remote

When developers write code they typically begin with a simple serial code and build upon it until all of the required functionality is present. The following set of examples were developed to demonstrate this iterative process of evolving a simple serial program to an efficient, fully-distributed *HPX* application. For this demonstration, we implemented a 1D heat distribution problem. This calculation simulates the diffusion of heat across a ring from an initialized state to some user-defined point in the future. It does this by breaking each portion of the ring into discrete segments and using the current segment's temperature and the temperature of the surrounding segments to calculate the temperature of the current segment in the next timestep as shown by Fig. **??** below.

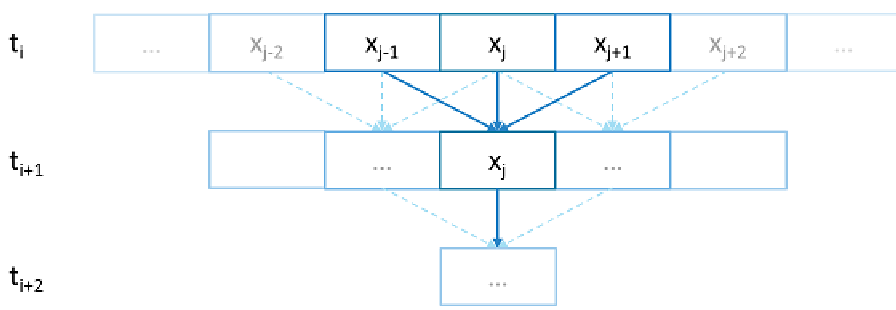

Fig. 2.2: Heat diffusion example program flow.

We parallelize this code over the following eight examples:

- Example 1
- Example 2
- Example 3

- Example 4
- Example 5
- Example 6
- Example 7
- Example 8

The first example is straight serial code. In this code we instantiate a vector U that contains two vectors of doubles as seen in the structure stepper.

```
struct stepper
{
    // Our partition type
    typedef double partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
    static double heat(double left, double middle, double right)
    {
        return middle + (k * dt / (dx * dx)) * (left - 2 * middle + right);
    }

    // do all the work on 'nx' data points for 'nt' time steps
    space do_work(std::size_t nx, std::size_t nt)
    {
        // U[t][i] is the state of position i at time t.
        std::vector<space> U(2);
        for (space& s : U)
            s.resize(nx);

        // Initial conditions: f(0, i) = i
        for (std::size_t i = 0; i != nx; ++i)
            U[0][i] = double(i);

        // Actual time step loop
        for (std::size_t t = 0; t != nt; ++t)
        {
            space const& current = U[t % 2];
            space& next = U[(t + 1) % 2];

            next[0] = heat(current[nx - 1], current[0], current[1]);

            for (std::size_t i = 1; i != nx - 1; ++i)
                next[i] = heat(current[i - 1], current[i], current[i + 1]);

            next[nx - 1] = heat(current[nx - 2], current[nx - 1], current[0]);
        }

        // Return the solution at time-step 'nt'.
        return U[nt % 2];
    }
```

(continues on next page)

(continued from previous page)

```
};
```

Each element in the vector of doubles represents a single grid point. To calculate the change in heat distribution, the temperature of each grid point, along with its neighbors, is passed to the function `heat`. In order to improve readability, references named `current` and `next` are created which, depending on the time step, point to the first and second vector of doubles. The first vector of doubles is initialized with a simple heat ramp. After calling the heat function with the data in the `current` vector, the results are placed into the `next` vector.

In example 2 we employ a technique called futurization. Futurization is a method by which we can easily transform a code that is serially executed into a code that creates asynchronous threads. In the simplest case this involves replacing a variable with a future to a variable, a function with a future to a function, and adding a `.get()` at the point where a value is actually needed. The code below shows how this technique was applied to the `struct stepper`.

```
struct stepper
{
    // Our partition type
    typedef hpx::shared_future<double> partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
    static double heat(double left, double middle, double right)
    {
        return middle + (k * dt / (dx * dx)) * (left - 2 * middle + right);
    }

    // do all the work on 'nx' data points for 'nt' time steps
    hpx::future<space> do_work(std::size_t nx, std::size_t nt)
    {
        using hpx::dataflow;
        using hpx::unwrapping;

        // U[t][i] is the state of position i at time t.
        std::vector<space> U(2);
        for (space& s : U)
            s.resize(nx);

        // Initial conditions: f(0, i) = i
        for (std::size_t i = 0; i != nx; ++i)
            U[0][i] = hpx::make_ready_future(double(i));

        auto Op = unwrapping(&stepper::heat);

        // Actual time step loop
        for (std::size_t t = 0; t != nt; ++t)
        {
            space const& current = U[t % 2];
            space& next = U[(t + 1) % 2];

            // WHEN U[t][i-1], U[t][i], and U[t][i+1] have been computed, THEN we
            // can compute U[t+1][i]
            for (std::size_t i = 0; i != nx; ++i)
```

(continues on next page)

(continued from previous page)

```
            {
                next[i] =
                    dataflow(hpx::launch::async, Op, current[idx(i, -1, nx)],
                        current[i], current[idx(i, +1, nx)]);
            }
        }

        // Now the asynchronous computation is running; the above for-loop does not
        // wait on anything. There is no implicit waiting at the end of each timestep;
        // the computation of each U[t][i] will begin as soon as its dependencies
        // are ready and hardware is available.

        // Return the solution at time-step 'nt'.
        return hpx::when_all(U[nt % 2]);
    }
};
```

In example 2, we redefine our partition type as a `shared_future` and, in `main`, create the object `result`, which is a future to a vector of partitions. We use `result` to represent the last vector in a string of vectors created for each timestep. In order to move to the next timestep, the values of a partition and its neighbors must be passed to `heat` once the futures that contain them are ready. In *HPX*, we have an LCO (Local Control Object) named Dataflow that assists the programmer in expressing this dependency. Dataflow allows us to pass the results of a set of futures to a specified function when the futures are ready. Dataflow takes three types of arguments, one which instructs the dataflow on how to perform the function call (async or sync), the function to call (in this case `Op`), and futures to the arguments that will be passed to the function. When called, dataflow immediately returns a future to the result of the specified function. This allows users to string dataflows together and construct an execution tree.

After the values of the futures in dataflow are ready, the values must be pulled out of the future container to be passed to the function `heat`. In order to do this, we use the HPX facility `unwrapping`, which underneath calls `.get()` on each of the futures so that the function `heat` will be passed doubles and not futures to doubles.

By setting up the algorithm this way, the program will be able to execute as quickly as the dependencies of each future are met. Unfortunately, this example runs terribly slow. This increase in execution time is caused by the overheads needed to create a future for each data point. Because the work done within each call to heat is very small, the overhead of creating and scheduling each of the three futures is greater than that of the actual useful work! In order to amortize the overheads of our synchronization techniques, we need to be able to control the amount of work that will be done with each future. We call this amount of work per overhead grain size.

In example 3, we return to our serial code to figure out how to control the grain size of our program. The strategy that we employ is to create "partitions" of data points. The user can define how many partitions are created and how many data points are contained in each partition. This is accomplished by creating the `struct partition`, which contains a member object `data_`, a vector of doubles that holds the data points assigned to a particular instance of `partition`.

In example 4, we take advantage of the partition setup by redefining `space` to be a vector of shared_futures with each future representing a partition. In this manner, each future represents several data points. Because the user can define how many data points are in each partition, and, therefore, how many data points are represented by one future, a user can control the grainsize of the simulation. The rest of the code is then futurized in the same manner as example 2. It should be noted how strikingly similar example 4 is to example 2.

Example 4 finally shows good results. This code scales equivalently to the OpenMP version. While these results are promising, there are more opportunities to improve the application's scalability. Currently, this code only runs on one *locality*, but to get the full benefit of *HPX*, we need to be able to distribute the work to other machines in a cluster. We begin to add this functionality in example 5.

In order to run on a distributed system, a large amount of boilerplate code must be added. Fortunately, *HPX* provides us with the concept of a *component*, which saves us from having to write quite as much code. A component is an object that can be remotely accessed using its global address. Components are made of two parts: a server and a client class. While the client class is not required, abstracting the server behind a client allows us to ensure type safety instead of having to pass around pointers to global objects. Example 5 renames example 4's `struct partition` to `partition_data` and adds serialization support. Next, we add the server side representation of the data in the structure `partition_server`. `Partition_server` inherits from `hpx::components::component_base`, which contains a server-side component boilerplate. The boilerplate code allows a component's public members to be accessible anywhere on the machine via its Global Identifier (GID). To encapsulate the component, we create a client side helper class. This object allows us to create new instances of our component and access its members without having to know its GID. In addition, we are using the client class to assist us with managing our asynchrony. For example, our client class `partition`'s member function `get_data()` returns a future to `partition_data get_data()`. This struct inherits its boilerplate code from `hpx::components::client_base`.

In the structure `stepper`, we have also had to make some changes to accommodate a distributed environment. In order to get the data from a particular neighboring partition, which could be remote, we must retrieve the data from all of the neighboring partitions. These retrievals are asynchronous and the function `heat_part_data`, which, amongst other things, calls `heat`, should not be called unless the data from the neighboring partitions have arrived. Therefore, it should come as no surprise that we synchronize this operation with another instance of dataflow (found in `heat_part`). This dataflow receives futures to the data in the current and surrounding partitions by calling `get_data()` on each respective partition. When these futures are ready, dataflow passes them to the `unwrapping` function, which extracts the shared_array of doubles and passes them to the lambda. The lambda calls `heat_part_data` on the *locality*, which the middle partition is on.

Although this example could run distributed, it only runs on one *locality*, as it always uses `hpx::find_here()` as the target for the functions to run on.

In example 6, we begin to distribute the partition data on different nodes. This is accomplished in `stepper::do_work()` by passing the GID of the *locality* where we wish to create the partition to the partition constructor.

```
    for (std::size_t i = 0; i != np; ++i)
        U[0][i] = partition(localities[locidx(i, np, nl)], nx, double(i));
```

We distribute the partitions evenly based on the number of localities used, which is described in the function `locidx`. Because some of the data needed to update the partition in `heat_part` could now be on a new *locality*, we must devise a way of moving data to the *locality* of the middle partition. We accomplished this by adding a switch in the function `get_data()` that returns the end element of the `buffer data_` if it is from the left partition or the first element of the buffer if the data is from the right partition. In this way only the necessary elements, not the whole buffer, are exchanged between nodes. The reader should be reminded that this exchange of end elements occurs in the function `get_data()` and, therefore, is executed asynchronously.

Now that we have the code running in distributed, it is time to make some optimizations. The function `heat_part` spends most of its time on two tasks: retrieving remote data and working on the data in the middle partition. Because we know that the data for the middle partition is local, we can overlap the work on the middle partition with that of the possibly remote call of `get_data()`. This algorithmic change, which was implemented in example 7, can be seen below:

```
    // The partitioned operator, it invokes the heat operator above on all elements
    // of a partition.
    static partition heat_part(
        partition const& left, partition const& middle, partition const& right)
    {
        using hpx::dataflow;
        using hpx::unwrapping;

        hpx::shared_future<partition_data> middle_data =
            middle.get_data(partition_server::middle_partition);
```

(continues on next page)

(continued from previous page)

```
        hpx::future<partition_data> next_middle = middle_data.then(
            unwrapping([middle](partition_data const& m) -> partition_data {
                HPX_UNUSED(middle);

                // All local operations are performed once the middle data of
                // the previous time step becomes available.
                std::size_t size = m.size();
                partition_data next(size);
                for (std::size_t i = 1; i != size - 1; ++i)
                    next[i] = heat(m[i - 1], m[i], m[i + 1]);
                return next;
            }));

        return dataflow(hpx::launch::async,
            unwrapping([left, middle, right](partition_data next,
                           partition_data const& l, partition_data const& m,
                           partition_data const& r) -> partition {
                HPX_UNUSED(left);
                HPX_UNUSED(right);

                // Calculate the missing boundary elements once the
                // corresponding data has become available.
                std::size_t size = m.size();
                next[0] = heat(l[size - 1], m[0], m[1]);
                next[size - 1] = heat(m[size - 2], m[size - 1], r[0]);

                // The new partition_data will be allocated on the same locality
                // as 'middle'.
                return partition(middle.get_id(), std::move(next));
            }),
            std::move(next_middle),
            left.get_data(partition_server::left_partition), middle_data,
            right.get_data(partition_server::right_partition));
    }
```

Example 8 completes the futurization process and utilizes the full potential of *HPX* by distributing the program flow to multiple localities, usually defined as nodes in a cluster. It accomplishes this task by running an instance of *HPX* main on each *locality*. In order to coordinate the execution of the program, the `struct stepper` is wrapped into a component. In this way, each *locality* contains an instance of stepper that executes its own instance of the function `do_work()`. This scheme does create an interesting synchronization problem that must be solved. When the program flow was being coordinated on the head node, the GID of each component was known. However, when we distribute the program flow, each partition has no notion of the GID of its neighbor if the next partition is on another *locality*. In order to make the GIDs of neighboring partitions visible to each other, we created two buffers to store the GIDs of the remote neighboring partitions on the left and right respectively. These buffers are filled by sending the GID of newly created edge partitions to the right and left buffers of the neighboring localities.

In order to finish the simulation, the solution vectors named `result` are then gathered together on *locality* 0 and added into a vector of spaces `overall_result` using the *HPX* functions `gather_id` and `gather_here`.

Example 8 completes this example series, which takes the serial code of example 1 and incrementally morphs it into a fully distributed parallel code. This evolution was guided by the simple principles of futurization, the knowledge of grainsize, and utilization of components. Applying these techniques easily facilitates the scalable parallelization of most applications.

2.3.8 Serializing user-defined types

In order to facilitate the sending and receiving of complex datatypes HPX provides a serialization abstraction.

Just like boost, hpx allows users to serialize user-defined types by either providing the serializer as a member function or defining the serialization as a free function.

Unlike Boost HPX doesn't acknowledge second unsigned int parameter, it is solely there to preserve API compatibility with Boost Serialization

This is tutorial was heavily inspired by Boost's serialization concepts[24].

Setup

The source code for this example can be found here: `custom_serialization.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.custom_serialization
```

To run the program type:

```
$ ./bin/custom_serialization
```

This should print:

```
Rectangle(Point(x=0,y=0),Point(x=0,y=5))
gravity.g = 9.81%
```

Serialization Requirements

In order to serialize objects in HPX, at least one of the following criteria must be met:

In the case of default constructible objects:

- The object is an empty type.
- Has a serialization function as shown in this tutorial.
- All members are accessible publicly and they can be used in structured binding contexts.

Otherwise:

- They need to have special serialization support.

[24] https://www.boost.org/doc/libs/1_79_0/libs/serialization/doc/serialization.html

Member function serialization

```
struct point_member_serialization
{
    int x{0};
    int y{0};

    // Required when defining the serialization function as private
    // In this case it isn't
    // Provides serialization access to HPX
    friend class hpx::serialization::access;

    // Second argument exists solely for compatibility with boost serialize
    // it is NOT processed by HPX in any way.
    template <typename Archive>
    void serialize(Archive& ar, unsigned int const)
    {
        // clang-format off
        ar & x & y;
        // clang-format on
    }
};

// Allow bitwise serialization
HPX_IS_BITWISE_SERIALIZABLE(point_member_serialization)
```

Notice that `point_member_serialization` is defined as bitwise serializable (see *Bitwise serialization for bitwise copyable data* for more details). HPX is also able to recursively serialize composite classes and structs given that its members are serializable.

```
struct rectangle_member_serialization
{
    point_member_serialization top_left;
    point_member_serialization lower_right;

    template <typename Archive>
    void serialize(Archive& ar, unsigned int const)
    {
        // clang-format off
        ar & top_left & lower_right;
        // clang-format on
    }
};
```

Free function serialization

In order to decouple your models from HPX, HPX also allows for the definition of free function serializers.

```
struct rectangle_free
{
    point_member_serialization top_left;
    point_member_serialization lower_right;
};

template <typename Archive>
void serialize(Archive& ar, rectangle_free& pt, unsigned int const)
{
    // clang-format off
    ar & pt.lower_right & pt.top_left;
    // clang-format on
}
```

Even if you can't modify a class to befriend it, you can still be able to serialize your class provided that your class is default constructable and you are able to reconstruct it yourself.

```
class point_class
{
public:
    point_class(int x, int y)
      : x(x)
      , y(y)
    {
    }

    point_class() = default;

    [[nodiscard]] int get_x() const noexcept
    {
        return x;
    }

    [[nodiscard]] int get_y() const noexcept
    {
        return y;
    }

private:
    int x;
    int y;
};

template <typename Archive>
void load(Archive& ar, point_class& pt, unsigned int const)
{
    int x, y;
    ar >> x >> y;
    pt = point_class(x, y);
```

(continues on next page)

(continued from previous page)

```
}

template <typename Archive>
void save(Archive& ar, point_class const& pt, unsigned int const)
{
    ar << pt.get_x() << pt.get_y();
}

// This tells HPX that you have spilt your serialize function into
// load and save
HPX_SERIALIZATION_SPLIT_FREE(point_class)
```

Serializing non default constructable classes

Some classes don't provide any default constructor.

```
class planet_weight_calculator
{
public:
    explicit planet_weight_calculator(double g)
      : g(g)
    {
    }

    template <class Archive>
    friend void save_construct_data(
        Archive&, planet_weight_calculator const*, unsigned int);

    [[nodiscard]] double get_g() const
    {
        return g;
    }

private:
    // Provides serialization access to HPX
    friend class hpx::serialization::access;
    template <class Archive>
    void serialize(Archive&, unsigned int const)
    {
        // Serialization will be done in the save_construct_data
        // Still needs to be defined
    }

    double g;
};
```

In this case you have to define a `save_construct_data` and `load_construct_data` in which you do the serialization yourself.

```
template <class Archive>
inline void save_construct_data(Archive& ar,
```

(continues on next page)

(continued from previous page)

```
    planet_weight_calculator const* weight_calc, unsigned int const)
{
    ar << weight_calc->g;    // Do all of your serialization here
}

template <class Archive>
inline void load_construct_data(
    Archive& ar, planet_weight_calculator* weight_calc, unsigned int const)
{
    double g;
    ar >> g;

    // ::new(ptr) construct new object at given address
    hpx::construct_at(weight_calc, g);
}
```

Bitwise serialization for bitwise copyable data

When sending non arithmetic types not defined by std::is_arithmetic[25], HPX has to (de)serialize each object separately. However, if the class you are trying to send classes consists only of bitwise copyable datatypes, you may mark your class as such. Then HPX will serialize your object bitwise instead of element wise. This has enormous benefits, especially when sending a vector/array of your class. To define your class as such you need to call `HPX_IS_BITWISE_SERIALIZABLE(T)` with your desired custom class.

```
struct point_member_serialization
{
    int x{0};
    int y{0};

    // Required when defining the serialization function as private
    // In this case it isn't
    // Provides serialization access to HPX
    friend class hpx::serialization::access;

    // Second argument exists solely for compatibility with boost serialize
    // it is NOT processed by HPX in any way.
    template <typename Archive>
    void serialize(Archive& ar, unsigned int const)
    {
        // clang-format off
        ar & x & y;
        // clang-format on
    }
};

// Allow bitwise serialization
HPX_IS_BITWISE_SERIALIZABLE(point_member_serialization)
```

2.3.9 Termination detection

This example demonstrates how to use *HPX*'s termination detection API to ensure all asynchronous work has completed before shutting down the runtime. This is particularly useful when you need to guarantee that all posted tasks have finished execution before the application exits.

Overview

The termination detection API provides a way to wait for all local *HPX*-threads to complete their work. This is essential in scenarios where you spawn asynchronous tasks using *hpx::post* or *hpx::async* and need to ensure they all finish before the runtime shuts down.

The API supports several use cases:

- **Basic usage**: Wait indefinitely for all tasks to complete
- **Timeout**: Wait for a specified duration
- **Deadline**: Wait until a specific time point
- **Cancellation**: Support for cancellation tokens to interrupt the wait

Setup

The source code for this example can be found here: `termination_detection.cpp`.

To compile this program, go to your *HPX* build directory (see *Building HPX* for information on configuring and building *HPX*) and enter:

```
$ make examples.quickstart.termination_detection
```

To run the program type:

```
$ ./bin/termination_detection
```

This will execute all four examples demonstrating different usage patterns of the termination detection API.

Walkthrough

The example demonstrates four different usage patterns of the termination detection API. Let's examine each one:

Basic usage

The simplest form waits indefinitely for all local threads to complete:

This is useful when you want to ensure all work is done before shutting down, and you don't have time constraints.

Timeout usage

You can specify a maximum duration to wait:

The function returns `true` if all threads completed within the timeout, or `false` if the timeout elapsed. This is useful when you want to give tasks a reasonable amount of time to complete but don't want to wait indefinitely.

Deadline usage

Similar to timeout, but you specify an absolute time point:

This is useful when you have a specific deadline by which all work must be completed.

Cancellation support

The most flexible form supports cancellation tokens:

This allows external control over the wait operation. You can request cancellation from another thread, which is useful in scenarios like graceful shutdown with user interruption support.

API Reference

The termination detection API is available in the `hpx::local` namespace:

void *hpx*::*local*::**termination_detection**()

Wait indefinitely for all local *HPX*-threads to complete.

bool *hpx*::*local*::**termination_detection**(*hpx*::chrono::steady_duration const &timeout)

Wait for all local *HPX*-threads to complete, with a timeout.

Parameters

timeout – Maximum duration to wait

Returns

`true` if all threads completed, `false` if timeout elapsed

bool *hpx*::*local*::**termination_detection**(*hpx*::chrono::steady_time_point const &deadline)

Wait for all local *HPX*-threads to complete, until a deadline.

Parameters

deadline – Absolute time point to wait until

Returns

`true` if all threads completed, `false` if deadline passed

bool *hpx*::*local*::**termination_detection**(*hpx*::*stop_token* stop_token, *hpx*::chrono::steady_duration const &timeout)

Wait for all local *HPX*-threads to complete, with cancellation support.

Parameters

- **stop_token** – Token that can be used to request cancellation
- **timeout** – Maximum duration to wait (defaults to maximum duration)

Returns

`true` if all threads completed, `false` if timeout elapsed or stop was requested

Use cases

The termination detection API is particularly useful in the following scenarios:

- **Graceful shutdown**: Ensure all background tasks complete before exiting
- **Testing**: Verify that all spawned tasks have finished in unit tests
- **Batch processing**: Wait for all work items in a batch to complete
- **Resource cleanup**: Ensure all tasks using shared resources have finished before cleanup

2.4 Manual

The manual is your comprehensive guide to *HPX*. It contains detailed information on how to build and use *HPX* in different scenarios.

2.4.1 Prerequisites

Supported platforms

At this time, *HPX* supports the following platforms. Other platforms may work, but we do not test *HPX* with other platforms, so please be warned.

Table 2.1: Supported Platforms for *HPX*

Name	Minimum Version	Architectures
Linux	2.6	x86-32, x86-64, k1om
BlueGeneQ	V1R2M0	PowerPC A2
Windows	Any Windows system	x86-32, x86-64
Mac OSX	Any OSX system	x86-64
ARM	Any ARM system	Any architecture
RISC-V	Any RISC-V system	Any architecture

Supported compilers

The table below shows the supported compilers for *HPX*.

Table 2.2: Supported Compilers for *HPX*

Name	Minimum Version	Latest tested
GNU Compiler Collection (g++)[26]	12.0	15.0
clang: a C language family frontend for LLVM[27]	16.0	20.0
Visual C++[28] (x64)	2022	2022

Software and libraries

The table below presents all the necessary prerequisites for building *HPX*.

Table 2.3: Software prerequisites for *HPX*

	Name	Minimum Version	Latest tested
Build System	CMake[29]	3.20	4.1
Required Libraries	Boost[30]	1.71.0	1.88.0
	Portable Hardware Locality (HWLOC)[31]	1.5	2.4

The most important dependencies are Boost[32] and Portable Hardware Locality (HWLOC)[33]. The installation of Boost is described in detail in Boost's Getting Started[34] document. A recent version of hwloc is required in order to support thread pinning and NUMA awareness and can be found in Hwloc Downloads[35].

HPX is written in 99.99% Standard C++ (the remaining 0.01% is platform specific assembly code). As such, *HPX* is compilable with almost any standards compliant C++ compiler. The code base takes advantage of C++ language and standard library features when available.

Note

When building Boost using gcc, please note that it is required to specify a `cxxflags=-std=c++20` command line argument to `b2` (`bjam`).

Note

In most configurations, *HPX* depends only on header-only Boost. Boost.Filesystem is required if the standard library does not support filesystem. The following are not needed by default, but are required in certain configurations: Boost.Chrono, Boost.DateTime, Boost.Log, Boost.LogSetup, Boost.Regex, and Boost.Thread.

Depending on the options you chose while building and installing *HPX*, you will find that *HPX* may depend on several other libraries such as those listed below.

Note

In order to use a high speed parcelport, we currently recommend configuring *HPX* to use MPI so that MPI can be used for communication between different localities. Please set the CMake variable `MPI_CXX_COMPILER` to your MPI C++ compiler wrapper if not detected automatically.

[35] https://www.open-mpi.org/software/hwloc/v1.11

Table 2.4: Optional software prerequisites for *HPX*

Name	Minimum version
google-perftools[36]	1.7.1
jemalloc[37]	2.1.0
mi-malloc[38]	1.0.0
Performance Application Programming Interface (PAPI)	

2.4.2 Getting *HPX*

Download a tarball of the latest release from *HPX* Downloads[39] and unpack it or clone the repository directly using `git`:

```
$ git clone https://github.com/TheHPXProject/hpx.git
```

It is also recommended that you check out the latest stable tag:

```
$ cd hpx
```

```
$ git checkout v2.0.0
```

2.4.3 Building *HPX*

Basic information

The build system for *HPX* is based on CMake[40], a cross-platform build-generator tool which is not responsible for building the project but rather generates the files needed by your build tool (GNU make, Visual Studio, etc.) for building *HPX*. If CMake is not already installed in your system, you can download it and install it here: CMake Downloads[41].

Once CMake[42] has been run, the build process can be started. The build process consists of the following parts:

- The *HPX* core libraries (target `core`): This forms the basic set of *HPX* libraries.
- *HPX* Examples (target `examples`): This target is enabled by default and builds all *HPX* examples (disable by setting `HPX_WITH_EXAMPLES:BOOL=Off`). *HPX* examples are part of the `all` target and are included in the installation if enabled.
- *HPX* Tests (target `tests`): This target builds the *HPX* test suite and is enabled by default (disable by setting `HPX_WITH_TESTS:BOOL =Off`). They are not built by the `all` target and have to be built separately.
- *HPX* Documentation (target `docs`): This target builds the documentation, and is not enabled by default (enable by setting `HPX_WITH_DOCUMENTATION:BOOL=On`. For more information see *Documentation*.

The *HPX* build process is highly configurable through CMake[43], and various CMake[44] variables influence the build process. A list with the most important CMake[45] variables can be found in the section that follows, while the complete

[36] https://code.google.com/p/gperftools
[37] http://jemalloc.net
[38] http://microsoft.github.io/mimalloc/
[39] https://hpx.dev/downloads/
[40] https://www.cmake.org
[41] https://www.cmake.org/cmake/resources/software.html
[42] https://www.cmake.org
[43] https://www.cmake.org
[44] https://www.cmake.org
[45] https://www.cmake.org

list of available CMake[46] variables is in *CMake options*. These variables can be used to refine the recipes that can be found at *Platform specific build recipes*, a section that shows some basic steps on how to build *HPX* for a specific platform.

In order to use *HPX*, only the core libraries are required. In order to use the optional libraries, you need to specify them as link dependencies in your build (See *Creating HPX projects*).

Most important CMake options

While building *HPX*, you are provided with multiple CMake options which correspond to different configurations. Below, there is a set of the most important and frequently used CMake options.

HPX_WITH_MALLOC

Use a custom allocator. Using a custom allocator tuned for multithreaded applications is very important for the performance of *HPX* applications. When debugging applications, it's useful to set this to `system`, as custom allocators can hide some memory-related bugs. Note that setting this to something other than `system` requires an external dependency.

HPX_WITH_CUDA

Enable support for CUDA. Use `CMAKE_CUDA_COMPILER` to set the CUDA compiler. This is a standard CMake[47] variable, like `CMAKE_CXX_COMPILER`.

HPX_WITH_PARCELPORT_MPI

Enable the MPI parcelport. This enables the use of MPI for the networking operations in the HPX runtime. The default value is `OFF` because it's not available on all systems and/or requires another dependency. However, it is the recommended parcelport.

HPX_WITH_PARCELPORT_TCP

Enable the TCP parcelport. Enables the use of TCP for networking in the runtime. The default value is `ON`. However, it's only recommended for debugging purposes, as it is slower than the MPI parcelport.

HPX_WITH_PARCELPORT_LCI

Enable the LCI parcelport. This enables the use of LCI for the networking operations in the HPX runtime. The default value is `OFF` because it's not available on all systems and/or requires another dependency. However, this experimental parcelport may provide better performance than the MPI parcelport. Please refer to *Using the LCI parcelport* for more information about the LCI parcelport.

HPX_WITH_APEX

Enable APEX integration. APEX[48] can be used to profile *HPX* applications. In particular, it provides information about individual tasks in the *HPX* runtime.

HPX_WITH_TRACY

Enable Tracy[49] integration. Tracy shows task lifecycle, work stealing, suspension, and (with *HPX_WITH_PARCEL_PROFILING*) distributed parcel events. See *Tracy integration* for build and attach instructions.

HPX_WITH_ITTNOTIFY

Enable Intel ITT API[50] integration. Requires VTune or any other Intel ITT API provider; point `Amplifier_ROOT` at the install (the name is legacy; it accepts any ITTNotify installation).

[46] https://www.cmake.org
[47] https://www.cmake.org
[48] https://uo-oaciss.github.io/apex/quickstarthpx/
[49] https://github.com/wolfpld/tracy
[50] https://github.com/intel/ittapi

HPX_WITH_PARCEL_PROFILING

Enable per-parcel profiling data. Adds per-parcel identifier and timestamp fields (creation time, start time, parcel id) that are carried on the wire and surfaced to whichever tracing backend is enabled. Defaults to `ON` when *HPX_WITH_APEX* is on, `OFF` otherwise.

HPX_WITH_TRACING_LIFECYCLE_EVENTS

Emit per-task lifecycle events (staged, created, executing, yielded, suspended, resumed, completed, deleted). Defaults to `ON`. Turn `OFF` to compile out the per-task hooks and their runtime connection check when profiling a workload where only causal or work-stealing events matter. The saving applies on Tracy builds; the other backends already treat these hooks as no-ops.

HPX_WITH_TRACING_CAUSAL_EVENTS

Emit causal-chain events (`future_fulfilled`, `future_exception_set`, `continuation_run`, `continuation_finished`, `handle_on_completed_fired`). Defaults to `ON`. Turning this `OFF` also elides the active-continuations counter update in `continuation_run` / `continuation_finished`. The saving applies on Tracy builds; the other backends already treat these hooks as no-ops.

HPX_WITH_TRACING_WORK_STEALING_EVENTS

Emit the work-stealing signal when a worker steals a task from another worker. Defaults to `ON`. Turn `OFF` when profiling a workload with heavy work stealing where the signal itself is not being consumed. The saving applies on Tracy builds; the other backends already treat this hook as a no-op.

HPX_WITH_GENERIC_CONTEXT_COROUTINES

Enable Boost. Context for task context switching. It must be enabled for non-x86 architectures such as ARM and Power.

HPX_WITH_MAX_CPU_COUNT

Set the maximum CPU count supported by *HPX*. The default value is 64, and should be set to a number at least as high as the number of cores on a system including virtual cores such as hyperthreads.

HPX_WITH_CXX_STANDARD

Set a specific C++ standard version e.g. `HPX_WITH_CXX_STANDARD=23`. The default and minimum value is `20`. Possible values are `20`, `23`, or `26`.

HPX_WITH_EXAMPLES

Build examples.

HPX_WITH_TESTS

Build tests.

HPX_WITH_DEBUG_POSTFIX

Set the postfix for debug libraries. The default is `d`. This variable is used to set `CMAKE_DEBUG_POSTFIX` and is only relevant for Debug builds or multi-configuration generators. The default rarely needs to be changed. It ensures that generated debug binaries have a different name than release binaries, which is important to avoid ABI problems when both debug and release binaries are installed on the same system.

For a complete list of available CMake[51] variables that influence the build of *HPX*, see *CMake options*.

[51] https://www.cmake.org

Build types

CMake[52] can be configured to generate project files suitable for builds that have enabled debugging support or for an optimized build (without debugging support). The CMake[53] variable used to set the build type is `CMAKE_BUILD_TYPE` (for more information see the CMake Documentation[54]). Available build types are:

- **Debug**: Full debug symbols are available as well as additional assertions to help debugging. To enable the debug build type for the *HPX* API, the C++ Macro `HPX_DEBUG` is defined.
- **RelWithDebInfo**: Release build with debugging symbols. This is most useful for profiling applications
- **Release**: Release build. This disables assertions and enables default compiler optimizations.
- **RelMinSize**: Release build with optimizations for small binary sizes.

Important

We currently don't guarantee ABI compatibility between Debug and Release builds. Please make sure that applications built against *HPX* use the same build type as you used to build *HPX*. For CMake builds, this means that the `CMAKE_BUILD_TYPE` variables have to match and for projects not using CMake[55], the `HPX_DEBUG` macro has to be set in debug mode.

Using CMake Presets

HPX provides a `CMakePresets.json` file which includes a variety of pre-defined build configurations. These presets allow you to easily configure the build for common scenarios without needing to manually specify multiple CMake variables.

To use a preset, you can use the `--preset` option with CMake:

```
$ cmake --preset <preset-name>
$ cmake --build --preset <preset-name>
```

Some of the available presets include:

- `default`: Standard release build with tests and examples enabled.
- `minimal`: Minimal build with only core features (no tests, examples, or tools).
- `full`: Full build with all standard features enabled.
- `debug`: Debug build with symbols and debug-optimized settings.
- `performance`: Build optimized for performance analysis with APEX profiling.
- `cuda`: Build with CUDA support (requires CUDA toolkit).
- `sycl`: Build with SYCL support (requires compatible compiler).
- `sanitizer-address`: Build with AddressSanitizer enabled.

For a full list of available presets, you can run:

```
$ cmake --list-presets
```

52 https://www.cmake.org
53 https://www.cmake.org
54 https://cmake.org/cmake/help/latest/variable/CMAKE_BUILD_TYPE.html
55 https://www.cmake.org

Platform specific build recipes

Unix variants

Once you have the source code and the dependencies and assuming all your dependencies are in paths known to CMake[56], the following gets you started:

1. First, set up a separate build directory to configure the project:

```
$ mkdir build && cd build
```

2. To configure the project you have the following options:

   - To build the core *HPX* libraries and examples, and install them to your chosen location (recommended):

   ```
   $ cmake -DCMAKE_INSTALL_PREFIX=/install/path ..
   ```

   Tip

   If you want to change CMake[57] variables for your build, it is usually a good idea to start with a clean build directory to avoid configuration problems. It is especially important that you use a clean build directory when changing between `Release` and `Debug` modes.

   - To install *HPX* to the default system folders, simply leave out the `CMAKE_INSTALL_PREFIX` option:

   ```
   $ cmake ..
   ```

   - If your dependencies are in custom locations, you may need to tell CMake[58] where to find them by passing one or more options to CMake[59] as shown below:

   ```
   $ cmake -DBoost_ROOT=/path/to/boost
         -DHwloc_ROOT=/path/to/hwloc
         -DTcmalloc_ROOT=/path/to/tcmalloc
         -DJemalloc_ROOT=/path/to/jemalloc
         [other CMake variable definitions]
         /path/to/source/tree
   ```

   For instance:

   ```
   $ cmake -DBoost_ROOT=~/packages/boost -DHwloc_ROOT=/packages/hwloc -DCMAKE_
   ↪INSTALL_PREFIX=~/packages/hpx ~/downloads/hpx_1.5.1
   ```

   - If you want to try *HPX* without using a custom allocator pass `-DHPX_WITH_MALLOC=system` to CMake[60]:

   ```
   $ cmake -DCMAKE_INSTALL_PREFIX=/install/path -DHPX_WITH_MALLOC=system ..
   ```

[56] https://www.cmake.org
[57] https://www.cmake.org
[58] https://www.cmake.org
[59] https://www.cmake.org
[60] https://www.cmake.org

Note

Please pay special attention to the section about *HPX_WITH_MALLOC:STRING* as this is crucial for getting decent performance.

Important

If you are building *HPX* for a system with more than 64 processing units, you must change the CMake[61] variable `HPX_WITH_MAX_CPU_COUNT` (to a value at least as big as the number of (virtual) cores on your system). Note that the default value is 64.

Caution

Compiling and linking *HPX* needs a considerable amount of memory. It is advisable that at least 2 GB of memory per parallel process is available.

3. Once the configuration is complete, to build the project you run:

```
$ cmake --build . --target install
```

Windows

Note

The following build recipes are mostly user-contributed and may be outdated. We always welcome updated and new build recipes.

To build *HPX* under Windows 10 x64 with Visual Studio 2015:

- Download the CMake V3.19 installer (or latest version) from here[62]
- Download the hwloc V1.11.0 (or the latest version) from here[63] and unpack it.
- Download the latest Boost libraries from here[64] and unpack them.
- Build the Boost DLLs and LIBs by using these commands from Command Line (or PowerShell). Open CMD/PowerShell inside the Boost dir and type in:

```
.\bootstrap.bat
```

This batch file will set up everything needed to create a successful build. Now execute:

```
.\b2.exe link=shared variant=release,debug architecture=x86 address-model=64␣
↪threading=multi --build-type=complete install
```

[61] https://www.cmake.org
[62] https://blog.kitware.com/cmake-3-19-0-available-for-download/
[63] https://www.open-mpi.org/software/hwloc/v2.11/
[64] https://www.boost.org/users/download/

This command will start a (very long) build of all available Boost libraries. Please, be patient.

- Open CMake-GUI.exe and set up your source directory (input field 'Where is the source code') to the *base directory* of the source code you downloaded from *HPX*'s GitHub pages. Here's an example of CMake path settings, which point to the `Documents/GitHub/hpx` folder:

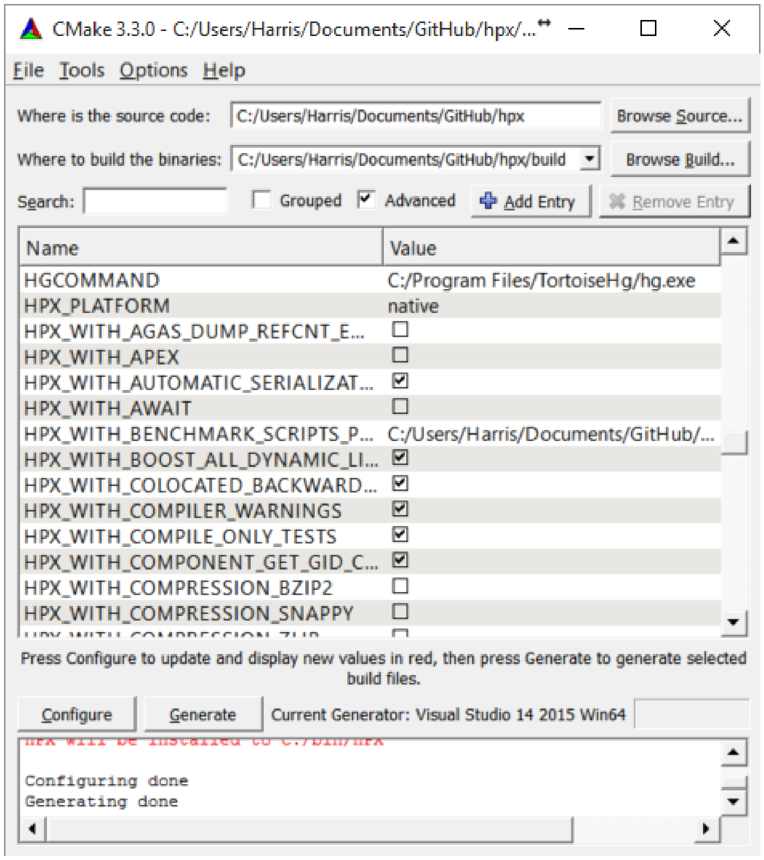

Fig. 2.3: Example CMake path settings.

Inside 'Where is the source-code' enter the base directory of your *HPX* source directory (do not enter the "src" sub-directory!). Inside 'Where to build the binaries' you should put in the path where all the building processes will happen. This is important because the building machinery will do an "out-of-tree" build. CMake will not touch or change the original source files in any way. Instead, it will generate Visual Studio Solution Files, which will build *HPX* packages out of the *HPX* source tree.

- Set new configuration variables (in CMake, not in Windows environment): `Boost_ROOT`, `Hwloc_ROOT`, `Asio_ROOT`, `CMAKE_INSTALL_PREFIX`. The meaning of these variables is as follows:
  - `Boost_ROOT` the *HPX* root directory of the unpacked Boost headers/cpp files.
  - `Hwloc_ROOT` the *HPX* root directory of the unpacked Portable Hardware Locality files.
  - `Asio_ROOT` the *HPX* root directory of the unpacked ASIO files. Alternatively use `HPX_WITH_FETCH_ASIO` with value `True`.
  - `CMAKE_INSTALL_PREFIX` the *HPX* root directory where the future builds of *HPX* should be installed.

Note

> *HPX* is a very large software collection, so it is not recommended to use the default `C:\Program Files\hpx`. Many users may prefer to use simpler paths *without* whitespace, like `C:\bin\hpx` or `D:\bin\hpx` etc.

To insert new env-vars click on "Add Entry" and then insert the name inside "Name", select `PATH` as Type and put the path-name in the "Path" text field. Repeat this for the first three variables.

This is how variable insertion will look:

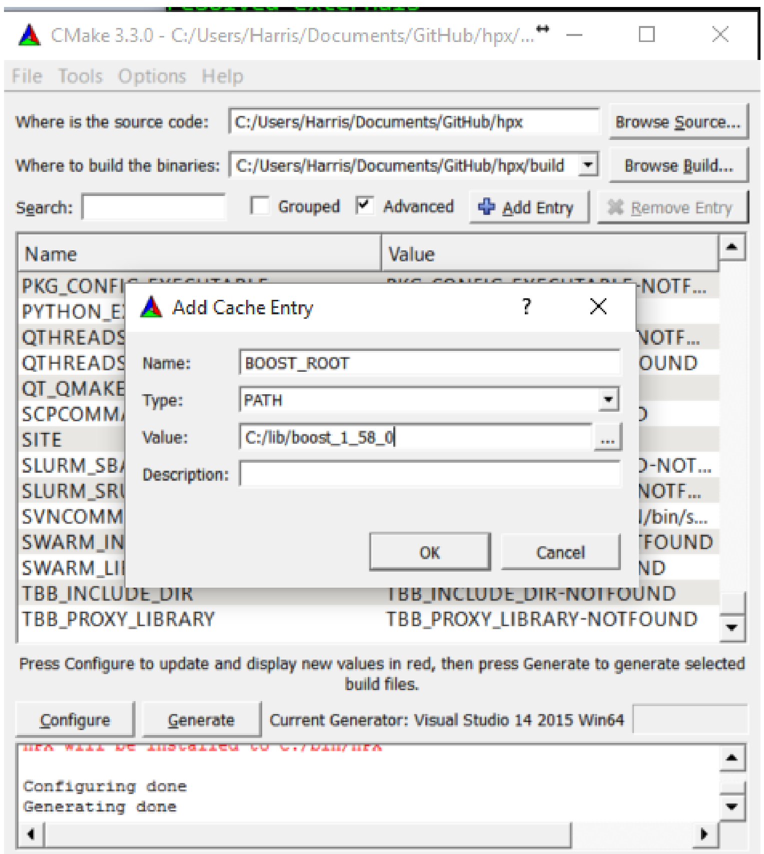

Fig. 2.4: Example CMake adding entry.

Alternatively, users could provide `Boost_LIBRARYDIR` instead of `Boost_ROOT`; the difference is that `Boost_LIBRARYDIR` should point to the subdirectory inside Boost root where all the compiled DLLs/LIBs are. For example, `Boost_LIBRARYDIR` may point to the `bin.v2` subdirectory under the Boost rootdir. It is important to keep the meanings of these two variables separated from each other: `Boost_DIR` points to the ROOT folder of the Boost library. `Boost_LIBRARYDIR` points to the subdir inside the Boost root folder where the compiled binaries are.

- Click the 'Configure' button of CMake-GUI. You will be immediately presented with a small window where you can select the C++ compiler to be used within Visual Studio. This has been tested using the latest v14 (a.k.a C++ 2015) but older versions should be sufficient too. Make sure to select the 64Bit compiler.
- After the generate process has finished successfully, click the 'Generate' button. Now, CMake will put new VS Solution files into the BUILD folder you selected at the beginning.
- Open Visual Studio and load the `HPX.sln` from your build folder.
- Go to `CMakePredefinedTargets` and build the `INSTALL` project:

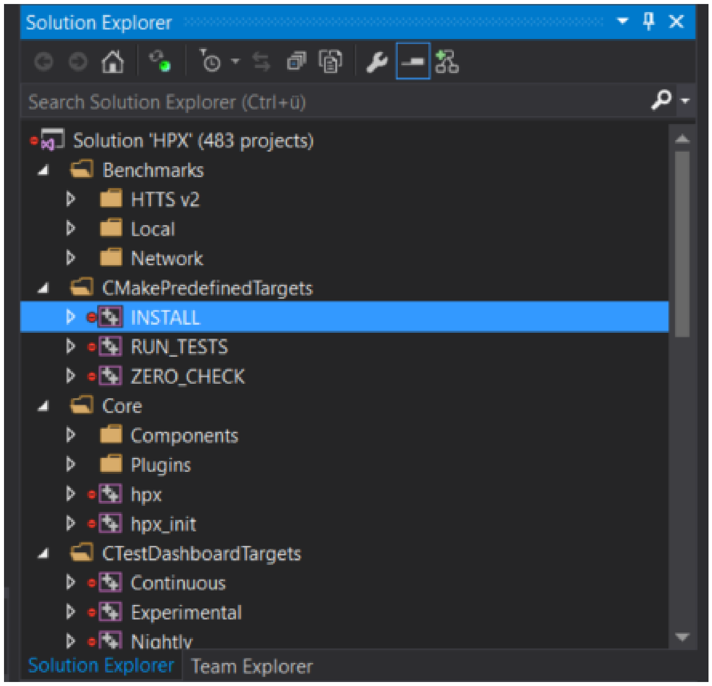

Fig. 2.5: Visual Studio INSTALL target.

It will take some time to compile everything, and in the end you should see an output similar to this one:

2.4.4 CMake options

In order to configure *HPX*, you can set a variety of options to allow CMake to generate your specific makefiles/project files. A list of the most important CMake options can be found in *Most important CMake options*, while this section includes the comprehensive list.

Variables that influence how *HPX* is built

The options are split into these categories:

- *Generic options*
- *Build Targets options*
- *Thread Manager options*
- *AGAS options*
- *Parcelport options*
- *Profiling options*
- *Debugging options*
- *Modules options*

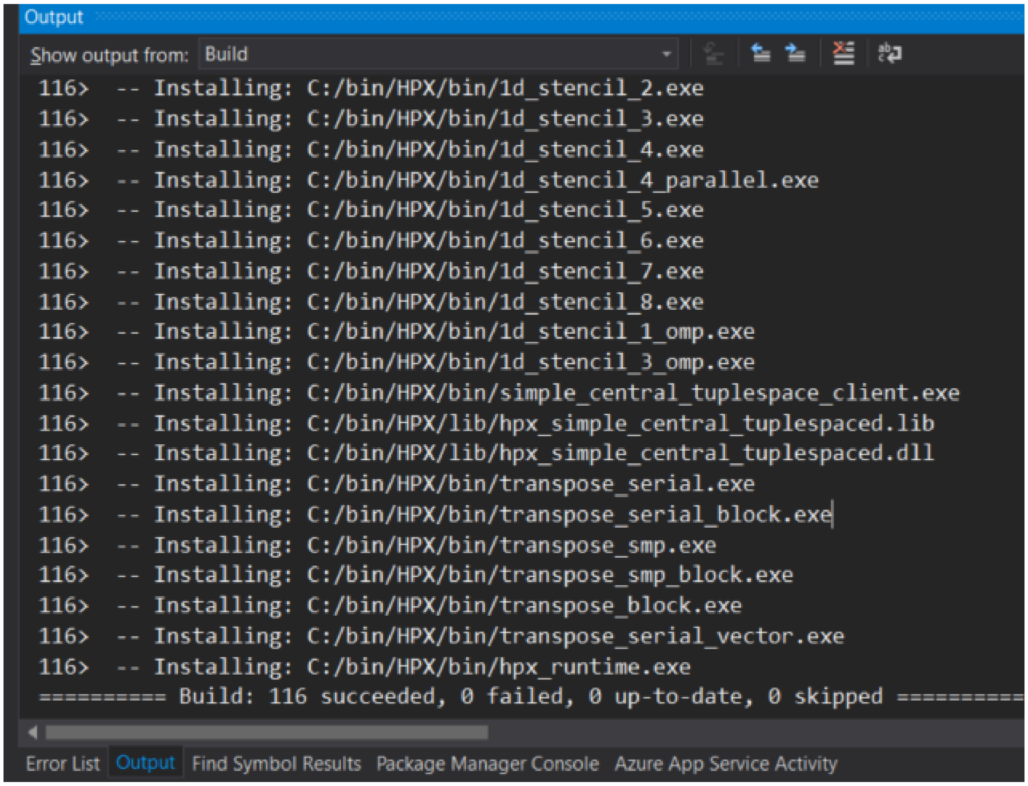

Fig. 2.6: Visual Studio build output.

Generic options

- *HPX_WITH_AUTOMATIC_SERIALIZATION_REGISTRATION:BOOL*
- *HPX_WITH_BUILD_BINARY_PACKAGE:BOOL*
- *HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL*
- *HPX_WITH_COMPILER_WARNINGS:BOOL*
- *HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL*
- *HPX_WITH_COMPRESSION_BZIP2:BOOL*
- *HPX_WITH_COMPRESSION_SNAPPY:BOOL*
- *HPX_WITH_COMPRESSION_ZLIB:BOOL*
- *HPX_WITH_CONTRACTS_MODE:STRING*
- *HPX_WITH_CUDA:BOOL*
- *HPX_WITH_CXX20_STD_EXECUTION_POLICES:INTERNAL*
- *HPX_WITH_CXX_MODULES:BOOL*
- *HPX_WITH_CXX_STANDARD:STRING*
- *HPX_WITH_DATAPAR_BACKEND:STRING*
- *HPX_WITH_DEPRECATION_WARNINGS:BOOL*
- *HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL*

- *HPX_WITH_DYNAMIC_HPX_MAIN:BOOL*
- *HPX_WITH_FAULT_TOLERANCE:BOOL*
- *HPX_WITH_FORCE_DISCONNECT:BOOL*
- *HPX_WITH_FULL_RPATH:BOOL*
- *HPX_WITH_GCC_VERSION_CHECK:BOOL*
- *HPX_WITH_GENERIC_CONTEXT_COROUTINES:BOOL*
- *HPX_WITH_GIT_HOOKS:BOOL*
- *HPX_WITH_HIDDEN_VISIBILITY:BOOL*
- *HPX_WITH_HIP:BOOL*
- *HPX_WITH_HIPSYCL:BOOL*
- *HPX_WITH_IGNORE_COMPILER_COMPATIBILITY:BOOL*
- *HPX_WITH_LOGGING:BOOL*
- *HPX_WITH_MALLOC:STRING*
- *HPX_WITH_MODULES_AS_STATIC_LIBRARIES:BOOL*
- *HPX_WITH_MODULE_COMPATIBILITY_HEADERS:BOOL*
- *HPX_WITH_NICE_THREADLEVEL:BOOL*
- *HPX_WITH_PARCEL_COALESCING:BOOL*
- *HPX_WITH_PKGCONFIG:BOOL*
- *HPX_WITH_PRECOMPILED_HEADERS:BOOL*
- *HPX_WITH_PSEUDO_DEPENDENCIES:BOOL*
- *HPX_WITH_RUN_MAIN_EVERYWHERE:BOOL*
- *HPX_WITH_STACKOVERFLOW_DETECTION:BOOL*
- *HPX_WITH_STATIC_LINKING:BOOL*
- *HPX_WITH_SUPPORT_NO_UNIQUE_ADDRESS_ATTRIBUTE:BOOL*
- *HPX_WITH_SYCL:BOOL*
- *HPX_WITH_SYCL_FLAGS:STRING*
- *HPX_WITH_UNITY_BUILD:BOOL*
- *HPX_WITH_VIM_YCM:BOOL*
- *HPX_WITH_ZERO_COPY_SERIALIZATION_THRESHOLD:STRING*

HPX_WITH_AUTOMATIC_SERIALIZATION_REGISTRATION:BOOL

Use automatic serialization registration for actions and functions. This affects compatibility between HPX applications compiled with different compilers (default ON)

HPX_WITH_BUILD_BINARY_PACKAGE:BOOL

Build HPX on the build infrastructure on any LINUX distribution (default: OFF).

HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL

Verify that no modules are cross-referenced from a different module category (default: OFF)

`HPX_WITH_COMPILER_WARNINGS:BOOL`
Enable compiler warnings (default: ON)

`HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL`
Turn compiler warnings into errors (default: OFF)

`HPX_WITH_COMPRESSION_BZIP2:BOOL`
Enable bzip2 compression for parcel data (default: OFF).

`HPX_WITH_COMPRESSION_SNAPPY:BOOL`
Enable snappy compression for parcel data (default: OFF).

`HPX_WITH_COMPRESSION_ZLIB:BOOL`
Enable zlib compression for parcel data (default: OFF).

`HPX_WITH_CONTRACTS_MODE:STRING`
Contract evaluation mode for pre-C++26 compilers, options are: ENFORCE, QUICK_ENFORCE, OBSERVE, IGNORE

`HPX_WITH_CUDA:BOOL`
Enable support for CUDA (default: OFF)

`HPX_WITH_CXX20_STD_EXECUTION_POLICES:INTERNAL`

`HPX_WITH_CXX_MODULES:BOOL`
Enable exposing C++20 modules (default: OFF).

`HPX_WITH_CXX_STANDARD:STRING`
Set the C++ standard to use when compiling HPX itself. (default: 20)

`HPX_WITH_DATAPAR_BACKEND:STRING`
Define which vectorization library should be used. Options are: VC, EVE, STD_EXPERIMENTAL_SIMD, SVE, EMULATE, NONE

`HPX_WITH_DEPRECATION_WARNINGS:BOOL`
Enable warnings for deprecated facilities (default: ON).

`HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL`
Disables the mechanism that produces debug output for caught signals and unhandled exceptions (default: OFF)

`HPX_WITH_DYNAMIC_HPX_MAIN:BOOL`
Enable dynamic overload of system `main()` (Linux and Apple only, default: ON)

`HPX_WITH_FAULT_TOLERANCE:BOOL`
Build HPX to tolerate failures of nodes, i.e. ignore errors in active communication channels (default: OFF)

`HPX_WITH_FORCE_DISCONNECT:BOOL`
Build HPX to support forceful disconnect of localities (default: OFF)

`HPX_WITH_FULL_RPATH:BOOL`
Build and link HPX libraries and executables with full RPATHs (default: ON)

`HPX_WITH_GCC_VERSION_CHECK:BOOL`
Don't ignore version reported by gcc (default: ON)

`HPX_WITH_GENERIC_CONTEXT_COROUTINES:BOOL`
Use Boost.Context as the underlying coroutines context switch implementation.

HPX_WITH_GIT_HOOKS:BOOL
Enable git commit hooks for formatting checks on commit (default: OFF).

HPX_WITH_HIDDEN_VISIBILITY:BOOL
Use -fvisibility=hidden for builds on platforms which support it (default OFF)

HPX_WITH_HIP:BOOL
Enable compilation with HIPCC (default: OFF)

HPX_WITH_HIPSYCL:BOOL
Use hipsycl cmake integration (default: OFF)

HPX_WITH_IGNORE_COMPILER_COMPATIBILITY:BOOL
Ignore compiler incompatibility in dependent projects (default: ON).

HPX_WITH_LOGGING:BOOL
Build HPX with logging enabled (default: ON).

HPX_WITH_MALLOC:STRING
Define which allocator should be linked in. Options are: system, tcmalloc, jemalloc, mimalloc, tbbmalloc, and custom (default is: tcmalloc)

HPX_WITH_MODULES_AS_STATIC_LIBRARIES:BOOL
Compile HPX modules as STATIC (whole-archive) libraries instead of OBJECT libraries (Default: ON)

HPX_WITH_MODULE_COMPATIBILITY_HEADERS:BOOL
Generate backwards-compatibility headers for HPX Modules (default: OFF)

HPX_WITH_NICE_THREADLEVEL:BOOL
Set HPX worker threads to have high NICE level (may impact performance) (default: OFF)

HPX_WITH_PARCEL_COALESCING:BOOL
Enable the parcel coalescing plugin (default: ON).

HPX_WITH_PKGCONFIG:BOOL
Enable generation of pkgconfig files (default: ON on Linux without CUDA/HIP, otherwise OFF)

HPX_WITH_PRECOMPILED_HEADERS:BOOL
Enable precompiled headers for certain build targets (experimental) (default OFF)

HPX_WITH_PSEUDO_DEPENDENCIES:BOOL
Turn compiler warnings into errors (default: ON)

HPX_WITH_RUN_MAIN_EVERYWHERE:BOOL
Run hpx_main by default on all localities (default: OFF, deprecated, will be removed).

HPX_WITH_STACKOVERFLOW_DETECTION:BOOL
Enable stackoverflow detection for HPX threads/coroutines (default: OFF, debug: ON).

HPX_WITH_STATIC_LINKING:BOOL
Compile HPX statically linked libraries (Default: OFF)

HPX_WITH_SUPPORT_NO_UNIQUE_ADDRESS_ATTRIBUTE:BOOL
Enable the use of the [[no_unique_address]] attribute (default: ON)

HPX_WITH_SYCL:BOOL
Enable support for Sycl (default: OFF)

HPX_WITH_SYCL_FLAGS:STRING
Sycl compile flags for selecting specific targets (default: empty)

HPX_WITH_UNITY_BUILD:BOOL
Enable unity build for certain build targets (default OFF)

HPX_WITH_VIM_YCM:BOOL
Generate HPX completion file for VIM YouCompleteMe plugin

HPX_WITH_ZERO_COPY_SERIALIZATION_THRESHOLD:STRING
The threshold in bytes to when perform zero copy optimizations (default: 8192)

Build Targets options

- *HPX_WITH_ASIO_TAG:STRING*
- *HPX_WITH_COMPILE_ONLY_TESTS:BOOL*
- *HPX_WITH_DISTRIBUTED_RUNTIME:BOOL*
- *HPX_WITH_DOCUMENTATION:BOOL*
- *HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS:STRING*
- *HPX_WITH_EXAMPLES:BOOL*
- *HPX_WITH_EXAMPLES_HDF5:BOOL*
- *HPX_WITH_EXAMPLES_OPENMP:BOOL*
- *HPX_WITH_EXAMPLES_QT4:BOOL*
- *HPX_WITH_EXAMPLES_QTHREADS:BOOL*

HPX_WITH_ASIO_TAG:STRING

Asio repository tag or branch

HPX_WITH_COMPILE_ONLY_TESTS:BOOL

Create build system support for compile time only HPX tests (default ON)

HPX_WITH_DISTRIBUTED_RUNTIME:BOOL

Enable the distributed runtime (default: ON). Turning off the distributed runtime completely disallows the creation and use of components and actions. Turning this option off is experimental!

HPX_WITH_DOCUMENTATION:BOOL

Build the HPX documentation (default OFF).

HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS:STRING

List of documentation output formats to generate. Valid options are html;singlehtml;latexpdf;man. Multiple values can be separated with semicolons. (default html).

HPX_WITH_EXAMPLES:BOOL

Build the HPX examples (default ON)

HPX_WITH_EXAMPLES_HDF5:BOOL

Enable examples requiring HDF5 support (default: OFF).

HPX_WITH_EXAMPLES_OPENMP:BOOL

Enable examples requiring OpenMP support (default: OFF).

HPX_WITH_EXAMPLES_QT4:BOOL

Enable examples requiring Qt4 support (default: OFF).

HPX_WITH_EXAMPLES_QTHREADS:BOOL

Enable examples requiring QThreads support (default: OFF).

HPX_WITH_EXAMPLES_TASKBENCH:BOOL

Enable the task-bench example (fetched from upstream StanfordLegion/task-bench, default: OFF).

HPX_WITH_EXAMPLES_TBB:BOOL

Enable examples requiring TBB support (default: OFF).

HPX_WITH_EXECUTABLE_PREFIX:STRING

Executable prefix (default none), '**hpx_**' useful for system install.

HPX_WITH_FAIL_COMPILE_TESTS:BOOL
Create build system support for fail compile HPX tests (default ON)

HPX_WITH_FETCH_APEX:BOOL
Use FetchContent to fetch APEX. By default an installed APEX will be used. (default: OFF)

HPX_WITH_FETCH_ASIO:BOOL
Use FetchContent to fetch Asio. By default an installed Asio will be used. (default: OFF)

HPX_WITH_FETCH_BOOST:BOOL
Use FetchContent to fetch Boost. By default an installed Boost will be used. (default: OFF)

HPX_WITH_FETCH_GASNET:BOOL
Use FetchContent to fetch GASNET. By default an installed GASNET will be used. (default: OFF).

HPX_WITH_FETCH_HWLOC:BOOL
Use FetchContent to fetch Hwloc. By default an installed Hwloc will be used. (default: OFF)

HPX_WITH_FETCH_LCI:BOOL
Use FetchContent to fetch LCI. By default an installed LCI will be used. (default: OFF)

HPX_WITH_FETCH_LCW:BOOL
Use FetchContent to fetch LCW. By default an installed LCW will be used. (default: OFF)

HPX_WITH_FETCH_TRACY:BOOL
Use FetchContent to fetch Tracy. By default an installed Tracy will be used. (default: OFF)

HPX_WITH_IO_COUNTERS:BOOL
Enable IO counters (default: ON)

HPX_WITH_LCI_BOOTSTRAP_MPI:BOOL
Configure the autofetched LCI with mpi bootstrap support (default: OFF)

HPX_WITH_LCI_TAG:STRING
LCI repository tag or branch

HPX_WITH_LCW_TAG:STRING
LCW repository tag or branch

HPX_WITH_NANOBENCH:BOOL
Use Nanobench for performance tests. Nanobench will be fetched using FetchContent (default: OFF)

HPX_WITH_PARALLEL_LINK_JOBS:STRING
Number of Parallel link jobs while building hpx (only for Ninja as generator) (default 2)

HPX_WITH_TESTS:BOOL
Build the HPX tests (default ON)

HPX_WITH_TESTS_BENCHMARKS:BOOL
Build HPX benchmark tests (default: ON)

HPX_WITH_TESTS_EXAMPLES:BOOL
Add HPX examples as tests (default: ON)

HPX_WITH_TESTS_EXTERNAL_BUILD:BOOL
Build external cmake build tests (default: ON)

HPX_WITH_TESTS_HEADERS:BOOL
Build HPX header tests (default: OFF)

HPX_WITH_TESTS_REGRESSIONS:BOOL
Build HPX regression tests (default: ON)

HPX_WITH_TESTS_UNIT:BOOL
Build HPX unit tests (default: ON)

HPX_WITH_THRUST:BOOL
Enable support for NVIDIA Thrust integration (default: ON when CUDA is enabled, OFF otherwise)

HPX_WITH_TOOLS:BOOL
Build HPX tools (default: OFF)

Thread Manager options

- *HPX_COROUTINES_WITH_SWAP_CONTEXT_EMULATION:BOOL*
- *HPX_COROUTINES_WITH_THREAD_SCHEDULE_HINT_RUNS_AS_CHILD:BOOL*
- *HPX_WITH_COROUTINE_COUNTERS:BOOL*
- *HPX_WITH_IO_POOL:BOOL*
- *HPX_WITH_MAX_CPU_COUNT:STRING*
- *HPX_WITH_MAX_NUMA_DOMAIN_COUNT:STRING*
- *HPX_WITH_SCHEDULER_LOCAL_STORAGE:BOOL*
- *HPX_WITH_SPINLOCK_DEADLOCK_DETECTION:BOOL*
- *HPX_WITH_SPINLOCK_POOL_NUM:STRING*
- *HPX_WITH_STACKTRACES:BOOL*
- *HPX_WITH_STACKTRACES_DEMANGLE_SYMBOLS:BOOL*
- *HPX_WITH_STACKTRACES_STATIC_SYMBOLS:BOOL*
- *HPX_WITH_THREAD_BACKTRACE_DEPTH:STRING*
- *HPX_WITH_THREAD_BACKTRACE_ON_SUSPENSION:BOOL*
- *HPX_WITH_THREAD_CREATION_AND_CLEANUP_RATES:BOOL*
- *HPX_WITH_THREAD_CUMULATIVE_COUNTS:BOOL*
- *HPX_WITH_THREAD_IDLE_RATES:BOOL*
- *HPX_WITH_THREAD_LOCAL_STORAGE:BOOL*
- *HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF:BOOL*
- *HPX_WITH_THREAD_QUEUE_WAITTIME:BOOL*
- *HPX_WITH_THREAD_STACK_MMAP:BOOL*
- *HPX_WITH_THREAD_STEALING_COUNTS:BOOL*
- *HPX_WITH_THREAD_TARGET_ADDRESS:BOOL*
- *HPX_WITH_TIMER_POOL:BOOL*
- *HPX_WITH_WORK_REQUESTING_SCHEDULERS:BOOL*

`HPX_COROUTINES_WITH_SWAP_CONTEXT_EMULATION:BOOL`
: Emulate SwapContext API for coroutines (Windows only, default: OFF)

`HPX_COROUTINES_WITH_THREAD_SCHEDULE_HINT_RUNS_AS_CHILD:BOOL`
: Futures attempt to run associated threads directly if those have not been started (default: OFF)

`HPX_WITH_COROUTINE_COUNTERS:BOOL`
: Enable keeping track of coroutine creation and rebind counts (default: OFF)

`HPX_WITH_IO_POOL:BOOL`
: Disable internal IO thread pool, do not change if not absolutely necessary (default: ON)

`HPX_WITH_MAX_CPU_COUNT:STRING`
: HPX applications will not use more that this number of OS-Threads (empty string means dynamic) (default: "")

`HPX_WITH_MAX_NUMA_DOMAIN_COUNT:STRING`
: HPX applications will not run on machines with more NUMA domains (default: 8)

`HPX_WITH_SCHEDULER_LOCAL_STORAGE:BOOL`
: Enable scheduler local storage for all HPX schedulers (default: OFF)

`HPX_WITH_SPINLOCK_DEADLOCK_DETECTION:BOOL`
: Enable spinlock deadlock detection (default: OFF)

`HPX_WITH_SPINLOCK_POOL_NUM:STRING`
: Number of elements a spinlock pool manages (default: 128)

`HPX_WITH_STACKTRACES:BOOL`
: Attach backtraces to HPX exceptions (default: ON)

`HPX_WITH_STACKTRACES_DEMANGLE_SYMBOLS:BOOL`
: Thread stack back trace symbols will be demangled (default: ON)

`HPX_WITH_STACKTRACES_STATIC_SYMBOLS:BOOL`
: Thread stack back trace will resolve static symbols (default: OFF)

`HPX_WITH_THREAD_BACKTRACE_DEPTH:STRING`
: Thread stack back trace depth being captured (default: 20)

`HPX_WITH_THREAD_BACKTRACE_ON_SUSPENSION:BOOL`
: Enable thread stack back trace being captured on suspension (default: OFF)

`HPX_WITH_THREAD_CREATION_AND_CLEANUP_RATES:BOOL`
: Enable measuring thread creation and cleanup times (default: OFF)

`HPX_WITH_THREAD_CUMULATIVE_COUNTS:BOOL`
: Enable keeping track of cumulative thread counts in the schedulers (default: ON)

`HPX_WITH_THREAD_IDLE_RATES:BOOL`
: Enable measuring the percentage of overhead times spent in the scheduler (default: OFF)

`HPX_WITH_THREAD_LOCAL_STORAGE:BOOL`
: Enable thread local storage for all HPX threads (default: OFF)

`HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF:BOOL`
: HPX scheduler threads do exponential backoff on idle queues (default: ON)

HPX_WITH_THREAD_QUEUE_WAITTIME:BOOL
Enable collecting queue wait times for threads (default: OFF)

HPX_WITH_THREAD_STACK_MMAP:BOOL
Use mmap for stack allocation on appropriate platforms

HPX_WITH_THREAD_STEALING_COUNTS:BOOL
Enable keeping track of counts of thread stealing incidents in the schedulers (default: OFF)

HPX_WITH_THREAD_TARGET_ADDRESS:BOOL
Enable storing target address in thread for NUMA awareness (default: OFF)

HPX_WITH_TIMER_POOL:BOOL
Disable internal timer thread pool, do not change if not absolutely necessary (default: ON)

HPX_WITH_WORK_REQUESTING_SCHEDULERS:BOOL
Enable work requesting scheduler (default: ON)

AGAS options

- *HPX_WITH_AGAS_DUMP_REFCNT_ENTRIES:BOOL*

HPX_WITH_AGAS_DUMP_REFCNT_ENTRIES:BOOL
Enable dumps of the AGAS refcnt tables to logs (default: OFF)

Parcelport options

- *HPX_WITH_NETWORKING:BOOL*
- *HPX_WITH_PARCELPORT_ACTION_COUNTERS:BOOL*
- *HPX_WITH_PARCELPORT_COUNTERS:BOOL*
- *HPX_WITH_PARCELPORT_GASNET:BOOL*
- *HPX_WITH_PARCELPORT_LCI:BOOL*
- *HPX_WITH_PARCELPORT_LCI_LOG:STRING*
- *HPX_WITH_PARCELPORT_LCI_PCOUNTER:STRING*
- *HPX_WITH_PARCELPORT_LCW:BOOL*
- *HPX_WITH_PARCELPORT_LCW_LOG:STRING*
- *HPX_WITH_PARCELPORT_LCW_PCOUNTER:STRING*
- *HPX_WITH_PARCELPORT_LIBFABRIC:BOOL*
- *HPX_WITH_PARCELPORT_MPI:BOOL*
- *HPX_WITH_PARCELPORT_TCP:BOOL*
- *HPX_WITH_PARCEL_PROFILING:BOOL*

HPX_WITH_NETWORKING:BOOL
Enable support for networking and multi-node runs (default: ON)

HPX_WITH_PARCELPORT_ACTION_COUNTERS:BOOL
Enable performance counters reporting parcelport statistics on a per-action basis.

HPX_WITH_PARCELPORT_COUNTERS:BOOL
Enable performance counters reporting parcelport statistics.

HPX_WITH_PARCELPORT_GASNET:BOOL
Enable the GASNET based parcelport.

HPX_WITH_PARCELPORT_LCI:BOOL
Enable the LCI based parcelport.

HPX_WITH_PARCELPORT_LCI_LOG:STRING
Enable the LCI-parcelport-specific logger

HPX_WITH_PARCELPORT_LCI_PCOUNTER:STRING
Enable the LCI-parcelport-specific performance counter

HPX_WITH_PARCELPORT_LCW:BOOL
Enable the LCW based parcelport.

HPX_WITH_PARCELPORT_LCW_LOG:STRING
Enable the LCW-parcelport-specific logger

HPX_WITH_PARCELPORT_LCW_PCOUNTER:STRING
Enable the LCW-parcelport-specific performance counter

HPX_WITH_PARCELPORT_LIBFABRIC:BOOL
Enable the libfabric based parcelport. This is currently an experimental feature

HPX_WITH_PARCELPORT_MPI:BOOL
Enable the MPI based parcelport.

HPX_WITH_PARCELPORT_TCP:BOOL
Enable the TCP based parcelport.

HPX_WITH_PARCEL_PROFILING:BOOL
Enable profiling data for parcels

Profiling options

- *HPX_LIKWID_WITH_LIKWID:BOOL*
- *HPX_WITH_APEX:BOOL*
- *HPX_WITH_ITTNOTIFY:BOOL*
- *HPX_WITH_PAPI:BOOL*
- *HPX_WITH_TRACY:BOOL*

HPX_LIKWID_WITH_LIKWID:BOOL
Enable Likwid instrumentation support.

HPX_WITH_APEX:BOOL
Enable APEX instrumentation support.

HPX_WITH_ITTNOTIFY:BOOL
Enable Amplifier (ITT) instrumentation support.

HPX_WITH_PAPI:BOOL
Enable the PAPI based performance counter.

HPX_WITH_TRACY:BOOL
Enable Tracy instrumentation support.

Debugging options

- *HPX_WITH_ASSERTS_AS_CONTRACT_ASSERTS:BOOL*
- *HPX_WITH_ATTACH_DEBUGGER_ON_TEST_FAILURE:BOOL*
- *HPX_WITH_CONTRACTS:BOOL*
- *HPX_WITH_PARALLEL_TESTS_BIND_NONE:BOOL*
- *HPX_WITH_SANITIZERS:BOOL*
- *HPX_WITH_TESTS_COMMAND_LINE:STRING*
- *HPX_WITH_TESTS_DEBUG_LOG:BOOL*
- *HPX_WITH_TESTS_DEBUG_LOG_DESTINATION:STRING*
- *HPX_WITH_TESTS_MAX_THREADS_PER_LOCALITY:STRING*
- *HPX_WITH_THREAD_DEBUG_INFO:BOOL*
- *HPX_WITH_THREAD_DESCRIPTION_FULL:BOOL*
- *HPX_WITH_THREAD_GUARD_PAGE:BOOL*
- *HPX_WITH_VALGRIND:BOOL*
- *HPX_WITH_VERIFY_LOCKS:BOOL*
- *HPX_WITH_VERIFY_LOCKS_BACKTRACE:BOOL*

HPX_WITH_ASSERTS_AS_CONTRACT_ASSERTS:BOOL
Swap hpx_assert with hpx_contract_assert

HPX_WITH_ATTACH_DEBUGGER_ON_TEST_FAILURE:BOOL
Break the debugger if a test has failed (default: OFF)

HPX_WITH_CONTRACTS:BOOL
Enable C++ contracts support in HPX

HPX_WITH_PARALLEL_TESTS_BIND_NONE:BOOL
Pass –hpx:bind=none to tests that may run in parallel (cmake -j flag) (default: OFF)

HPX_WITH_SANITIZERS:BOOL
Configure with sanitizer instrumentation support.

HPX_WITH_TESTS_COMMAND_LINE:STRING
Add given command line options to all tests run

HPX_WITH_TESTS_DEBUG_LOG:BOOL
Turn on debug logs (–hpx:debug-hpx-log) for tests (default: OFF)

HPX_WITH_TESTS_DEBUG_LOG_DESTINATION:STRING
Destination for test debug logs (default: cout)

HPX_WITH_TESTS_MAX_THREADS_PER_LOCALITY:STRING
Maximum number of threads to use for tests (default: 0, use the number of threads specified by the test)

HPX_WITH_THREAD_DEBUG_INFO:BOOL

Enable thread debugging information (default: OFF, implicitly enabled in debug builds)

HPX_WITH_THREAD_DESCRIPTION_FULL:BOOL

Use function address for thread description (default: OFF)

HPX_WITH_THREAD_GUARD_PAGE:BOOL

Enable thread guard page (default: ON)

HPX_WITH_VALGRIND:BOOL

Enable Valgrind instrumentation support.

HPX_WITH_VERIFY_LOCKS:BOOL

Enable lock verification code (default: OFF, enabled in debug builds)

HPX_WITH_VERIFY_LOCKS_BACKTRACE:BOOL

Enable thread stack back trace being captured on lock registration (to be used in combination with HPX_WITH_VERIFY_LOCKS=ON, default: OFF)

Modules options

- *HPX_ALLOCATOR_SUPPORT_WITH_CACHING:BOOL*
- *HPX_COMMAND_LINE_HANDLING_LOCAL_WITH_JSON_CONFIGURATION_FILES:BOOL*
- *HPX_DATASTRUCTURES_WITH_ADAPT_STD_TUPLE:BOOL*
- *HPX_DATASTRUCTURES_WITH_ADAPT_STD_VARIANT:BOOL*
- *HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY:BOOL*
- *HPX_FUNCTIONAL_WITH_BOOST_PLACEHOLDERS:BOOL*
- *HPX_IOSTREAM_WITH_WIDE_STREAMS:BOOL*
- *HPX_ITERATOR_SUPPORT_WITH_BOOST_ITERATOR_TRAVERSAL_TAG_COMPATIBILITY:BOOL*
- *HPX_LOGGING_WITH_SEPARATE_DESTINATIONS:BOOL*
- *HPX_SERIALIZATION_WITH_ALLOW_CONST_TUPLE_MEMBERS:BOOL*
- *HPX_SERIALIZATION_WITH_ALLOW_RAW_POINTER_SERIALIZATION:BOOL*
- *HPX_SERIALIZATION_WITH_ALL_TYPES_ARE_BITWISE_SERIALIZABLE:BOOL*
- *HPX_SERIALIZATION_WITH_BOOST_TYPES:BOOL*
- *HPX_SERIALIZATION_WITH_SUPPORTS_ENDIANESS:BOOL*
- *HPX_TOPOLOGY_WITH_ADDITIONAL_HWLOC_TESTING:BOOL*
- *HPX_WITH_POWER_COUNTER:BOOL*
- *HPX_WITH_SUPERVISION:BOOL*

HPX_ALLOCATOR_SUPPORT_WITH_CACHING:BOOL

Enable caching allocator. (default: ON)

HPX_COMMAND_LINE_HANDLING_LOCAL_WITH_JSON_CONFIGURATION_FILES:BOOL

Enable reading JSON formatted configuration files on the command line.

(default: OFF)

`HPX_DATASTRUCTURES_WITH_ADAPT_STD_TUPLE:BOOL`
Enable compatibility of hpx::get with std::tuple. (default: ON)

`HPX_DATASTRUCTURES_WITH_ADAPT_STD_VARIANT:BOOL`

Enable compatibility of hpx::get with std::variant.

(default: OFF)

`HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY:BOOL`
Enable Boost.FileSystem compatibility. (default: OFF)

`HPX_FUNCTIONAL_WITH_BOOST_PLACEHOLDERS:BOOL`
Enable support for Boost placeholder types. (default: OFF)

`HPX_IOSTREAM_WITH_WIDE_STREAMS:BOOL`
Enable wide IO streams. (default: OFF)

`HPX_ITERATOR_SUPPORT_WITH_BOOST_ITERATOR_TRAVERSAL_TAG_COMPATIBILITY:BOOL`
Enable Boost.Iterator traversal tag compatibility. (default: OFF)

`HPX_LOGGING_WITH_SEPARATE_DESTINATIONS:BOOL`
Enable separate logging channels for AGAS, timing, and parcel transport. (default: ON)

`HPX_SERIALIZATION_WITH_ALLOW_CONST_TUPLE_MEMBERS:BOOL`
Enable serializing std::tuple with const members. (default: OFF)

`HPX_SERIALIZATION_WITH_ALLOW_RAW_POINTER_SERIALIZATION:BOOL`
Enable serializing raw pointers. (default: OFF)

`HPX_SERIALIZATION_WITH_ALL_TYPES_ARE_BITWISE_SERIALIZABLE:BOOL`
Assume all types are bitwise serializable. (default: OFF)

`HPX_SERIALIZATION_WITH_BOOST_TYPES:BOOL`
Enable serialization of certain Boost types. (default: OFF)

`HPX_SERIALIZATION_WITH_SUPPORTS_ENDIANESS:BOOL`
Support endian conversion on inout and output archives. (default: OFF)

`HPX_TOPOLOGY_WITH_ADDITIONAL_HWLOC_TESTING:BOOL`

Enable HWLOC filtering that makes it report no cores, this is purely an

option supporting better testing - do not enable under normal circumstances. (default: OFF)

`HPX_WITH_POWER_COUNTER:BOOL`
Enable use of performance counters based on pwr library (default: OFF)

`HPX_WITH_SUPERVISION:BOOL`
Enable supervision functionalities. (default: OFF)

Additional tools and libraries used by *HPX*

Here is a list of additional libraries and tools that are either optionally supported by the build system or are optionally required for certain examples or tests. These libraries and tools can be detected by the *HPX* build system.

Each of the tools or libraries listed here will be automatically detected if they are installed in some standard location. If a tool or library is installed in a different location, you can specify its base directory by appending `_ROOT` to the variable name as listed below. For instance, to configure a custom directory for `Boost`, specify `Boost_ROOT=/custom/boost/root`.

`Boost_ROOT:PATH`

Specifies where to look for the Boost installation to be used for compiling *HPX*. Set this if CMake is not able to locate a suitable version of Boost. The directory specified here can be either the root of an installed Boost distribution or the directory where you unpacked and built Boost without installing it (with staged libraries).

`Hwloc_ROOT:PATH`

Specifies where to look for the hwloc library. Set this if CMake is not able to locate a suitable version of hwloc. Hwloc provides platform- independent support for extracting information about the used hardware architecture (number of cores, number of NUMA domains, hyperthreading, etc.). *HPX* utilizes this information if available.

`Papi_ROOT:PATH`

Specifies where to look for the PAPI library. The PAPI library is needed to compile a special component exposing PAPI hardware events and counters as *HPX* performance counters. This is not available on the Windows platform.

`Amplifier_ROOT:PATH`

Specifies where to look for one of the tools of the Intel Parallel Studio product, either Intel Amplifier or Intel Inspector. This should be set if the CMake variable `HPX_USE_ITT_NOTIFY` is set to `ON`. Enabling ITT support in *HPX* will integrate any application with the mentioned Intel tools, which customizes the generated information for your application and improves the generated diagnostics.

In addition, some of the examples may need the following variables:

`Hdf5_ROOT:PATH`

Specifies where to look for the Hierarchical Data Format V5 (HDF5) include files and libraries.

2.4.5 Using *HPX* on Compiler Explorer

Compiler Explorer[65] (CE) is a browser-based tool that compiles C++ code in real time and shows assembly, program output, and optimization results side by side. It is widely used for quick experiments, conference demos, and sharing reproducible snippets. This page explains how to build *HPX* for CE, how to link against its static libraries from a raw compiler command, and how to use the *sandbox header* that *HPX* ships specifically for constrained environments.

Sandbox environment constraints

CE executes compiled programs inside a Linux container (nsjail) with no network access and limited resources. The constraints that matter most for *HPX* are:

- No network namespace — sockets cannot be opened. Any attempt to initialise the distributed runtime will fail with `EACCES` at startup.
- A small PID budget (typically 32 PIDs) — *HPX* starts cleanly within this limit when the worker thread count is kept low.

[65] https://godbolt.org

- A short execution timeout — CE's public instance allows roughly 10 seconds. An *HPX* fork or self-hosted instance can relax this to 30 seconds, which is enough for benchmarks on problem sizes of one million elements or more.
- Static linking is required — the sandbox does not augment `LD_LIBRARY_PATH`, so shared *HPX* libraries are not found at runtime.

Building *HPX* for Compiler Explorer

HPX ships a `godbolt-minimal` configure preset in `CMakePresets.json` that encodes all the flags needed for a CE-compatible build:

```
$ cmake --preset godbolt-minimal
$ cmake --build --preset godbolt-minimal
```

This preset enables:

- `HPX_WITH_STATIC_LINKING=ON` — bundles everything into the `.a` archives that CE links against.
- `HPX_WITH_NETWORKING=OFF` — disables the parcelset so *HPX* never attempts to open a network socket.
- `HPX_WITH_FETCH_ASIO=ON` — downloads Asio via FetchContent, removing the need for a system-level Asio installation.
- `HPX_WITH_MALLOC=system` — uses the system allocator; avoids a jemalloc or tcmalloc dependency.
- `HPX_WITH_TESTS=OFF`, `HPX_WITH_EXAMPLES=OFF`, `HPX_WITH_DOCUMENTATION=OFF` — skips everything that CE does not need.

The preset produces four static libraries under `build/godbolt-minimal/lib/`:

```
libhpx_wrap.a
libhpx_init.a
libhpx.a
libhpx_core.a
```

These are the only artifacts that CE consumes.

Note

The `HPX_WITH_CXX_STANDARD` variable pins the C++ standard for the build (e.g. `-DHPX_WITH_CXX_STANDARD=20`). This is *HPX*'s own cache variable and is distinct from `CMAKE_CXX_STANDARD`, which *HPX* rejects unless `HPX_USE_CMAKE_CXX_STANDARD` is also set.

Linking without CMake

CE's backend compiles user code with a raw `g++` or `clang++` invocation. The complete set of flags needed is:

```
$ g++ -std=c++20 -O2 -o my_program my_program.cpp          \
    -isystem /path/to/hpx/include                            \
    -isystem /path/to/boost/include                          \
    -L/path/to/hpx/lib                                       \
    -DHPX_APPLICATION_EXPORTS                                \
    -Wl,-wrap=main                                           \
```

(continues on next page)

(continued from previous page)

```
    -lhpx_wrap -lhpx_init -lhpx -lhpx_core                  \
    -lpthread -ldl -lrt
```

Two details here are easy to get wrong:

Library link order. The order `hpx_wrap` → `hpx_init` → `hpx` → `hpx_core` must be preserved. Reversing it produces undefined-reference errors because `hpx_wrap` depends on symbols in `hpx_init`, which depends on the full runtime in `hpx`, which in turn depends on the core library.

The `-Wl,-wrap=main` flag. Including `hpx/hpx_main.hpp` (see *Re-use the main() function as the main HPX entry point*) works by re-routing control through *HPX*'s own entry point before the user's `main` is called. On Linux this is implemented via the linker's `--wrap` option; the flag must therefore appear on the *linker* command line, not merely in the compile flags. Without it, the *HPX* runtime is never initialised and all API calls crash at startup. See *Linux implementation* for a detailed explanation of the mechanism.

Important

`-DHPX_APPLICATION_EXPORTS` must be passed as a preprocessor definition when compiling application code against the static libraries. Omitting it causes link failures related to *HPX*'s symbol visibility macros.

Writing *HPX* code for Compiler Explorer

The simplest way to write an *HPX* program for CE is to include `hpx/hpx_main.hpp`. This header arranges for the *HPX* runtime to be initialised before `main` runs, so the body of `main` can call any *HPX* API function directly:

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>

#include <iostream>
#include <numeric>
#include <vector>

int main()
{
    std::vector<int> v(1'000'000);
    std::iota(v.begin(), v.end(), 0);

    long long sum = hpx::transform_reduce(
        hpx::execution::par, v.begin(), v.end(), 0LL,
        std::plus<>{}, [](int x) { return static_cast<long long>(x); });

    std::cout << "sum = " << sum << "\n";
}
```

Caution

Include `hpx/hpx_main.hpp` in exactly one translation unit — the file that contains `main`. Including it in more than one file causes a multiple definition error for the `include_libhpx_wrap` variable that controls runtime initialisation.

The hpx/experimental/sandbox.hpp header

HPX ships a header-only toolkit at `hpx/experimental/sandbox.hpp` designed specifically for code running in constrained environments. It provides:

- **Environment introspection** — `hpx::experimental::sandbox::detect_environment()` returns an `environment_info` struct describing the number of physical cores, processing units, NUMA domains, and active *HPX* worker threads. The `is_sandbox` flag is set when the `COMPILER_EXPLORER` or `HPX_SANDBOX` environment variable is present, letting code adapt its behaviour automatically.
- **Timing** — `hpx::experimental::sandbox::measure(fn, iterations)` runs a callable `fn` for `iterations` repetitions (with one warmup pass) and returns the mean execution time in milliseconds.
- **Comparative benchmarking** — `hpx::experimental::sandbox::benchmark(label, seq_fn, par_fn, iterations)` measures both a sequential and a parallel version of the same computation, computes speedup and parallel efficiency, and returns a `benchmark_report` struct. Calling `report.print(std::cout)` produces a fixed-width table that renders cleanly in CE's output pane.

A typical usage pattern looks like this:

```
#include <hpx/hpx_main.hpp>
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>
#include <hpx/experimental/sandbox.hpp>

#include <algorithm>
#include <iostream>
#include <numeric>
#include <vector>

int main()
{
    namespace sb = hpx::experimental::sandbox;

    sb::describe_environment(std::cout);

    std::vector<int> data(500'000);
    std::iota(data.begin(), data.end(), 0);

    auto report = sb::benchmark(
        "transform_reduce",
        [&]() {
            hpx::transform_reduce(
                hpx::execution::seq,
                data.begin(), data.end(), 0LL,
                std::plus<>{}, [](int x) { return (long long)x; });
        },
        [&]() {
            hpx::transform_reduce(
                hpx::execution::par,
                data.begin(), data.end(), 0LL,
                std::plus<>{}, [](int x) { return (long long)x; });
        });

    report.print(std::cout);
}
```

The output includes sequential and parallel mean times, speedup, parallel efficiency, and a verdict (`Excellent scaling`, `Good scaling`, `Moderate scaling`, `Limited scaling`, or `No speedup`).

> **Note**
>
> All functions in `hpx/experimental/sandbox.hpp` must be called from within a running *HPX* runtime, i.e., from an *HPX* thread. Calling them before *hpx::init* or after *hpx::finalize* is undefined behaviour. When using `hpx/hpx_main.hpp`, the body of `main` satisfies this requirement automatically.

Known limitations in sandboxed environments

- **Single locality only.** The distributed runtime can be compiled in (`HPX_WITH_DISTRIBUTED_RUNTIME=ON`) and actions on locality 0 work normally, but there is no way to launch a second locality from within CE's sandbox. Code that calls `hpx::find_all_localities()` or `hpx::get_num_localities()` will always see exactly one locality.
- **Networking is disabled.** `HPX_WITH_NETWORKING=OFF` means all parcelport-dependent functionality (remote actions, distributed data structures) is unavailable regardless of what the code requests.
- **Thread count is limited by the sandbox's CPU allocation.** CE's public instance typically exposes two cores. Use `--hpx:threads=N` on the command line or `hpx::init_params::cfg` in code to set the worker count explicitly rather than relying on hardware detection. See *Launching and configuring HPX applications* for details.
- **macOS link flag differs.** The `-Wl,-wrap=main` flag is Linux-specific. On macOS the linker uses `-Wl,-e,_initialize_main` instead. CE runs Linux containers, so this only matters when building the CE integration locally on macOS for testing.

2.4.6 Migration guide

The Migration Guide serves as a valuable resource for developers seeking to transition their parallel computing applications from different APIs (i.e. OpenMP, Intel Threading Building Blocks (TBB), MPI) to *HPX*. *HPX*, an advanced C++ library, offers a versatile and high-performance platform for parallel and distributed computing, providing a wide range of features and capabilities. This guide aims to assist developers in understanding the key differences between different APIs and *HPX*, and it provides step-by-step instructions for converting code to *HPX* code effectively.

Some general steps that can be used to migrate code to *HPX* code are the following:

1. Install *HPX* using the *Quick start* guide.
2. Include the *HPX* header files:

   Add the necessary header files for HPX at the beginning of your code, such as:

   ```
   #include <hpx/init.hpp>
   ```

3. Replace your code with *HPX* code using the guide that follows.
4. Use HPX-specific features and APIs:

   HPX provides additional features and APIs that can be used to take advantage of the library's capabilities. For example, you can use the HPX asynchronous execution to express fine-grained tasks and dependencies, or utilize HPX's distributed computing features for distributed memory systems.

5. Compile and run the *HPX* code:

   Compile the converted code with the *HPX* library and run it using the appropriate HPX runtime environment.

OpenMP

The OpenMP API supports multi-platform shared-memory parallel programming in C/C++. Typically it is used for loop-level parallelism, but it also supports function-level parallelism. Below are some examples on how to convert OpenMP to *HPX* code:

OpenMP parallel for loop

Parallel for loop

OpenMP code:

```
#pragma omp parallel for
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>

hpx::experimental::for_loop(hpx::execution::par, 0, n, [&](int i) {
    // loop body
});
```

In the above code, the OpenMP *#pragma omp parallel for* directive is replaced with *hpx::experimental::for_loop* from the *HPX* library. The loop body within the lambda function will be executed in parallel for each iteration.

Private variables

OpenMP code:

```
int x = 0;

#pragma omp parallel for private(x)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>

hpx::experimental::for_loop(hpx::execution::par, 0, n, [&](int i) {
        int x = 0; // Declare 'x' as a local variable inside the loop body
        // loop body
});
```

The variable *x* is declared as a local variable inside the loop body, ensuring that it is private to each thread.

Shared variables

OpenMP code:

```
int x = 0;

#pragma omp parallel for shared(x)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>

std::atomic<int> x = 0; // Declare 'x' as a shared variable outside the loop

hpx::experimental::for_loop(hpx::execution::par, 0, n, [&](int i) {
    // loop body
});
```

To ensure variable *x* is shared among all threads, you simply have to declare it as an atomic variable outside the *for_loop*.

Number of threads

OpenMP code:

```
#pragma omp parallel for num_threads(2)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>

hpx::execution::experimental::num_cores nc(2);

hpx::experimental::for_loop(hpx::execution::par.with(nc), 0, n, [&](int i) {
    // loop body
});
```

To declare the number of threads to be used for the parallel region, you can use *hpx::execution::experimental::num_cores* and pass the number of cores (*nc*) to *hpx::experimental::for_loop* using *hpx::execution::par.with(nc)*. This example uses 2 threads for the parallel loop.

Reduction

OpenMP code:

```
int s = 0;

#pragma omp parallel for reduction(+: s)
for (int i = 0; i < n; ++i) {
    s += i;
    // loop body
}
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>

int s = 0;

hpx::experimental::for_loop(hpx::execution::par, 0, n, reduction(s, 0, plus<>()), [&
↪](int i, int& accum) {
    accum += i;
    // loop body
});
```

The reduction clause specifies that the variable *s* should be reduced across iterations using the *plus*<> operation. It initializes *s* to *0* at the beginning of the loop and accumulates the values of *s* from each iteration using the + operator. The lambda function representing the loop body takes two parameters: *i*, which represents the loop index, and *accum*, which is the reduction variable *s*. The lambda function is executed for each iteration of the loop. The reduction ensures that the *accum* value is correctly accumulated across different iterations and threads.

Schedule

OpenMP code:

```
int s = 0;

// static scheduling with chunk size 1000
#pragma omp parallel for schedule(static, 1000)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>

hpx::execution::experimental::static_chunk_size cs(1000);

hpx::experimental::for_loop(hpx::execution::par.with(cs), 0, n, [&](int i) {
    // loop body
});
```

To define the scheduling type, you can use the corresponding execution policy from *hpx::execution::experimental*, define the chunk size (cs, here declared as 1000) and pass it to the to *hpx::experimental::for_loop* using *hpx::execution::par.with(cs)*.

Accordingly, other types of scheduling are available and can be used in a similar manner:

```
#include <hpx/execution.hpp>
hpx::execution::experimental::dynamic_chunk_size cs(1000);
```

```
#include <hpx/execution.hpp>
hpx::execution::experimental::guided_chunk_size cs(1000);
```

```
#include <hpx/execution.hpp>
hpx::execution::experimental::auto_chunk_size cs(1000);
```

OpenMP single thread

OpenMP code:

```
{   // parallel code
    #pragma omp single
    {
        // single-threaded code
    }
    // more parallel code
}
```

HPX equivalent:

```
#include <hpx/mutex.hpp>

hpx::mutex mtx;

{   // parallel code
    {   // single-threaded code
        std::scoped_lock l(mtx);
    }
    // more parallel code
}
```

To make sure that only one thread accesses a specific code within a parallel section you can use *hpx::mutex* and *std::scoped_lock* to take ownership of the given mutex *mtx*. For more information about mutexes please refer to *Mutex*.

OpenMP tasks

Simple tasks

OpenMP code:

```
// executed asynchronously by any available thread
#pragma omp task
{
    // task code
}
```

HPX equivalent:

```
#include <hpx/future.hpp>

auto future = hpx::async([](){
    // task code
});
```

or

```
#include <hpx/future.hpp>

hpx::post([](){
    // task code
}); // fire and forget
```

The tasks in *HPX* can be defined simply by using the `async` function and passing as argument the code you wish to run asynchronously. Another alternative is to use `post` which is a fire-and-forget method.

Tip

If you think you will like to synchronize your tasks later on, we suggest you use *hpx::async* which provides synchronization options, while *hpx::post* explicitly states that there is no return value or way to synchronize with the function execution. Synchronization options are listed below.

Task wait

OpenMP code:

```
#pragma omp task
{
    // task code
}

#pragma omp taskwait
// code after completion of task
```

HPX equivalent:

```
#include <hpx/future.hpp>

hpx::async([](){
    // task code
}).get(); // wait for the task to complete

// code after completion of task
```

The *get()* function can be used to ensure that the task created with *hpx::async* is completed before the code continues executing beyond that point.

Multiple tasks synchronization

OpenMP code:

```
#pragma omp task
{
    // task 1 code
}

#pragma omp task
{
    // task 2 code
}

#pragma omp taskwait
// code after completion of both tasks 1 and 2
```

HPX equivalent:

```
#include <hpx/future.hpp>

auto future1 = hpx::async([](){
    // task 1 code
});

auto future2 = hpx::async([](){
    // task 2 code
});

auto future = hpx::when_all(future1, future2).then([](auto&&){
    // code after completion of both tasks 1 and 2
});
```

If you would like to synchronize multiple tasks, you can use the *hpx::when_all* function to define which futures have to be ready and the *then()* function to declare what should be executed once these futures are ready.

Dependencies

OpenMP code:

```
int a = 10;
int b = 20;
int c = 0;

#pragma omp task depend(in: a, b) depend(out: c)
{
    // task code
    c = 100;
}
```

HPX equivalent:

```
#include <hpx/future.hpp>

int a = 10;
int b = 20;
int c = 0;

// Create a future representing 'a'
auto future_a = hpx::make_ready_future(a);

// Create a future representing 'b'
auto future_b = hpx::make_ready_future(b);

// Create a task that depends on 'a' and 'b' and executes 'task_code'
auto future_c = hpx::dataflow(
    []() {
        // task code
        return 100;
    },
    future_a, future_b);

c = future_c.get();
```

If one of the arguments of *hpx::dataflow* is a future, then it will wait for the future to be ready to launch the thread. Hence, to define the dependencies of tasks you have to create futures representing the variables that create dependencies and pass them as arguments to *hpx::dataflow*. *get()* is used to save the result of the future to the desired variable.

Nested tasks

OpenMP code:

```
#pragma omp task
{
    // Outer task code
    #pragma omp task
    {
        // Inner task code
```

(continues on next page)

(continued from previous page)

```
    }
}
```

HPX equivalent:

```
#include <hpx/future.hpp>

auto future_outer = hpx::async([](){
    // Outer task code

    hpx::async([](){
        // Inner task code
    });
});
```

or

```
#include <hpx/future.hpp>

auto future_outer = hpx::post([](){ // fire and forget
    // Outer task code

    hpx::post([](){ // fire and forget
        // Inner task code
    });
});
```

If you have nested tasks, you can simply use nested *hpx::async* or *hpx::post* calls. The implementation is similar if you want to take care of synchronization:

OpenMP code:

```
#pragma omp taskwait
{
    // Outer task code
    #pragma omp taskwait
    {
        // Inner task code
    }
}
```

HPX equivalent:

```
#include <hpx/future.hpp>

auto future_outer = hpx::async([]() {
    // Outer task code

    hpx::async([]() {
        // Inner task code
    }).get();    // Wait for the inner task to complete
});

future_outer.get();    // Wait for the outer task to complete
```

Task yield

OpenMP code:

```
#pragma omp task
{
    // code before yielding
    #pragma omp taskyield
    // code after yielding
}
```

HPX equivalent:

```
#include <hpx/future.hpp>
#include <hpx/thread.hpp>

auto future = hpx::async([](){
    // code before yielding
});

// yield execution to potentially allow other tasks to run
hpx::this_thread::yield();

// code after yielding
```

After creating a task using *hpx::async*, *hpx::this_thread::yield* can be used to reschedule the execution of threads, allowing other threads to run.

Task group

OpenMP code:

```
#pragma omp taskgroup
{
    #pragma omp task
    {
        // task 1 code
    }

    #pragma omp task
    {
        // task 2 code
    }
}
```

HPX equivalent:

```
#include <hpx/task_group.hpp>

// Declare a task group
hpx::experimental::task_group tg;

// Run the tasks
```

(continues on next page)

(continued from previous page)

```
tg.run([](){
    // task 1 code
});
tg.run(
    // task 2 code
});

// Wait for the task group
tg.wait();
```

To create task groups, you can use *hpx::experimental::task_group*. The function *run()* can be used to run each task within the task group, while *wait()* can be used to achieve synchronization. If you do not care about waiting for the task group to complete its execution, you can simply remove the *wait()* function.

OpenMP sections

OpenMP code:

```
#pragma omp sections
{
    #pragma omp section
    // section 1 code
    #pragma omp section
    // section 2 code
} // implicit synchronization
```

HPX equivalent:

```
#include <hpx/future.hpp>

auto future_section1 = hpx::async([](){
    // section 1 code
});
auto future_section2 = hpx::async([](){
    // section 2 code
);

// synchronization: wait for both sections to complete
hpx::wait_all(future_section1, future_section2);
```

Unlike tasks, there is an implicit synchronization barrier at the end of each *sections* directive in OpenMP. This synchronization is achieved using *hpx::wait_all* function.

Note

If the *nowait* clause is used in the *sections* directive, then you can just remove the *hpx::wait_all* function while keeping the rest of the code as it is.

Intel Threading Building Blocks (TBB)

Intel Threading Building Blocks (TBB) provides a high-level interface for parallelism and concurrent programming using standard ISO C++ code. Below are some examples on how to convert Intel Threading Building Blocks (TBB) to *HPX* code:

parallel_for

Intel Threading Building Blocks (TBB) code:

```
auto values = std::vector<double>(10000);

tbb::parallel_for( tbb::blocked_range<int>(0,values.size()),
                   [&](tbb::blocked_range<int> r)
{
    for (int i=r.begin(); i<r.end(); ++i)
    {
        // loop body
    }
});
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>

auto values = std::vector<double>(10000);

hpx::experimental::for_loop(hpx::execution::par, 0, values.size(), [&](int i) {
    // loop body
});
```

In the above code, *tbb::parallel_for* is replaced with *hpx::experimental::for_loop* from the *HPX* library. The loop body within the lambda function will be executed in parallel for each iteration.

parallel_for_each

Intel Threading Building Blocks (TBB) code:

```
auto values = std::vector<double>(10000);

tbb::parallel_for_each(values.begin(), values.end(), [&](){
    // loop body
});
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>

auto values = std::vector<double>(10000);

hpx::for_each(hpx::execution::par, values.begin(), values.end(), [&](){
```

(continues on next page)

(continued from previous page)

```
    // loop body
});
```

By utilizing *hpx::for_each* and specifying a parallel execution policy with *hpx::execution::par*, it is possible to transform *tbb::parallel_for_each* into its equivalent counterpart in *HPX*.

parallel_invoke

Intel Threading Building Blocks (TBB) code:

```
tbb::parallel_invoke(task1, task2, task3);
```

HPX equivalent:

```
#include <hpx/future.hpp>

hpx::wait_all(hpx::async(task1), hpx::async(task2), hpx::async(task3));
```

To convert *tbb::parallel_invoke* to *HPX*, we use *hpx::async* to asynchronously execute each task, which returns a future representing the result of each task. We then pass these futures to *hpx::when_all*, which waits for all the futures to complete before returning.

parallel_pipeline

Intel Threading Building Blocks (TBB) code:

```
tbb::parallel_pipeline(4,
    tbb::make_filter<void, int>(tbb::filter::serial_in_order,
        [](tbb::flow_control& fc) -> int {
            // Generate numbers from 1 to 10
            static int i = 1;
            if (i <= 10) {
                return i++;
            }
            else {
                fc.stop();
                return 0;
            }
        }) &
    tbb::make_filter<int, int>(tbb::filter::parallel,
        [](int num) -> int {
            // Multiply each number by 2
            return num * 2;
        }) &
    tbb::make_filter<int, void>(tbb::filter::serial_in_order,
        [](int num) {
            // Print the results
            std::cout << num << " ";
        })
);
```

HPX equivalent:

```
#include <iostream>
#include <vector>
#include <ranges>
#include <hpx/algorithm.hpp>

// generate the values
auto range = std::views::iota(1) | std::views::take(10);

// materialize the output vector
std::vector<int> results(10);

// in parallel execution of pipeline and transformation
hpx::ranges::transform(
    hpx::execution::par, range, result.begin(), [](int i) { return 2 * i; });

// print the modified vector
for (int i : result)
{
    std::cout << i << " ";
}
std::cout << std::endl;
```

The line *auto range = std::views::iota(1) | std::views::take(10);* generates a range of values using the *std::views::iota* function. It starts from the value 1 and generates an infinite sequence of incrementing values. The *std::views::take(10)* function is then applied to limit the sequence to the first 10 values. The result is stored in the *range* variable.

Hint

A view is a lightweight object that represents a particular view of a sequence or range. It acts as a read-only interface to the original data, providing a way to query and traverse the elements without making any copies or modifications.

Views can be composed and chained together to form complex pipelines of operations. These operations are evaluated lazily, meaning that the actual computation is performed only when the result is needed or consumed.

Since views perform lazy evaluation, we use *std::vector<int> results(10);* to meterialize the vector that will store the transformed values. The *hpx::ranges::transform* function is then used to perform a parallel transformation on the range. The transformed values will be written to the *results* vector.

Hint

Ranges enable loop fusion by combining multiple operations into a single parallel loop, eliminating waiting time and reducing overhead. Using ranges, you can express these operations as a pipeline of transformations on a sequence of elements. This pipeline is evaluated in a single pass, performing all the desired operations in parallel without the need to wait between them.

In addition, *HPX* enhances the benefits of range fusion by offering parallel execution policies, which can be used to optimize the execution of the fused loop across multiple threads.

parallel_reduce

Reduction

Intel Threading Building Blocks (TBB) code:

```
auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};

auto total = tbb::parallel_reduce(
                tbb::blocked_range<int>(0,values.size()),
                0.0,
                [&](tbb::blocked_range<int> r, double running_total)
                {
                    for (int i=r.begin(); i<r.end(); ++i)
                    {
                        running_total += values[i];
                    }

                    return running_total;
                },
                std::plus<double>());
```

HPX equivalent:

```
#include <hpx/numeric.hpp>

auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};

auto total = hpx::reduce(
    hpx::execution::par, values.begin(), values.end(), 0, std::plus{});
```

By utilizing *hpx::reduce* and specifying a parallel execution policy with *hpx::execution::par*, it is possible to transform *tbb::parallel_reduce* into its equivalent counterpart in *HPX*. As demonstrated in the previous example, the management of intermediate results is seamlessly handled internally by *HPX*, eliminating the need for explicit consideration.

Transformation & Reduction

Intel Threading Building Blocks (TBB) code:

```
auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};

auto transform_function(double current_value){
    // transformation code
}

auto total = tbb::parallel_reduce(
                tbb::blocked_range<int>(0,values.size()),
                0.0,
                [&](tbb::blocked_range<int> r, double transformed_val)
                {
                    for (int i=r.begin(); i<r.end(); ++i)
```

(continues on next page)

(continued from previous page)

```
                    {
                        transformed_val += transform_function(values[i]);
                    }
                    return transformed_val;
                },
                std::plus<double>());
```

HPX equivalent:

```
#include <hpx/numeric.hpp>

auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};

auto transform_function(double current_value)
{
    // transformation code
}

auto total = hpx::transform_reduce(hpx::execution::par, values.begin(),
    values.end(), 0, std::plus{},
    [&](double current_value) { return transform_function(current_value); });
```

In situations where certain values require transformation before the reduction process, *HPX* provides a straightforward solution through *hpx::transform_reduce*. The *transform_function()* allows for the application of the desired transformation to each value.

parallel_scan

Intel Threading Building Blocks (TBB) code:

```
tbb::parallel_scan(tbb::blocked_range<size_t>(0, input.size()),
    0,
    [&input, &output](const tbb::blocked_range<size_t>& range, int& partial_sum, bool is_
↪final_scan) {
        for (size_t i = range.begin(); i != range.end(); ++i) {
            partial_sum += input[i];
            if (is_final_scan) {
                output[i] = partial_sum;
            }
        }
        return partial_sum;
    },
    [](int left_sum, int right_sum) {
        return left_sum + right_sum;
    }
);
```

HPX equivalent:

```
#include <hpx/numeric.hpp>

hpx::inclusive_scan(hpx::execution::par, input.begin(), input.end(),
```

(continues on next page)

(continued from previous page)

```
    output.begin(),
    [](const int& left, const int& right) { return left + right; });
```

hpx::inclusive_scan with *hpx::execution::par* as execution policy can be used to perform a prefix scan in parallel. The management of intermediate results is seamlessly handled internally by *HPX*, eliminating the need for explicit consideration. *input.begin()* and *input.end()* refer to the beginning and end of the sequence of elements the algorithm will be applied to respectively. *output.begin()* refers to the beginning of the destination, while the last argument specifies the function which will be invoked for each of the values of the input sequence.

Apart from *hpx::inclusive_scan*, *HPX* provides its users with *hpx::exclusive_scan*. The key difference between inclusive scan and exclusive scan lies in the treatment of the current element during the scan operation. In an inclusive scan, each element in the output sequence includes the contribution of the corresponding element in the input sequence, while in an exclusive scan, the current element in the input sequence does not contribute to the corresponding element in the output sequence.

parallel_sort

Intel Threading Building Blocks (TBB) code:

```
std::vector<int> numbers = {9, 2, 7, 1, 5, 3};

tbb::parallel_sort(numbers.begin(), numbers.end());
```

HPX equivalent:

```
#include <hpx/algorithm.hpp>

std::vector<int> numbers = {9, 2, 7, 1, 5, 3};

hpx::sort(hpx::execution::par, numbers.begin(), numbers.end());
```

hpx::sort provides an equivalent functionality to *tbb::parallel_sort*. When given a parallel execution policy with *hpx::execution::par*, the algorithm employs parallel execution, allowing for efficient sorting across available threads.

task_group

Intel Threading Building Blocks (TBB) code:

```
// Declare a task group
tbb::task_group tg;

// Run the tasks
tg.run(task1);
tg.run(task2);

// Wait for the task group
tg.wait();
```

HPX equivalent:

```
#include <hpx/task_group.hpp>

// Declare a task group
hpx::experimental::task_group tg;

// Run the tasks
tg.run(task1);
tg.run(task2);

// Wait for the task group
tg.wait();
```

HPX drew inspiration from Intel Threading Building Blocks (TBB) to introduce the *hpx::experimental::task_group* feature. Therefore, utilizing *hpx::experimental::task_group* provides an equivalent functionality to *tbb::task_group*.

MPI

MPI is a standardized communication protocol and library that allows multiple processes or nodes in a parallel computing system to exchange data and coordinate their execution.

List of MPI-*HPX* functions

MPI function	*HPX* equivalent
MPI_Allgather	*hpx::collectives::all_gather*
MPI_Allreduce	*hpx::collectives::all_reduce*
MPI_Alltoall	*hpx::collectives::all_to_all*
MPI_Barrier	*hpx::distributed::barrier*
MPI_Bcast	`hpx::collectives::broadcast_to` and `hpx::collectives::broadcast_from()` used with `get()`
MPI_Comm_siz	*hpx::get_num_localities*
MPI_Comm_ra	`hpx::get_locality_id`
MPI_Exscan	`hpx::collectives::exclusive_scan` used with `get()`
MPI_Gather	`hpx::collectives::gather_here` and `hpx::collectives::gather_there()` used with `get()`
MPI_Irecv	`hpx::collectives::get`
MPI_Isend	`hpx::collectives::set`
MPI_Reduce	*hpx::collectives::reduce_here* and *hpx::collectives::reduce_there* used with `get()`
MPI_Scan	`hpx::collectives::inclusive_scan` used with `get()`
MPI_Scatter	`hpx::collectives::scatter_to` and `hpx::collectives::scatter_from()`
MPI_Wait	`hpx::collectives::get` used with a future i.e. `setf.get()`

MPI_Send & MPI_Recv

Let's assume we have the following simple message passing code where each process sends a message to the next process in a circular manner. The exchanged message is modified and printed to the console.

MPI code:

```
#include <cstddef>
#include <cstdint>
#include <iostream>
#include <mpi.h>
#include <vector>

constexpr int times = 2;

int main(int argc, char *argv[]) {
MPI_Init(&argc, &argv);

int num_localities;
MPI_Comm_size(MPI_COMM_WORLD, &num_localities);

int this_locality;
MPI_Comm_rank(MPI_COMM_WORLD, &this_locality);

int next_locality = (this_locality + 1) % num_localities;
std::vector<int> msg_vec = {0, 1};

int cnt = 0;
int msg = msg_vec[this_locality];

int recv_msg;
MPI_Request request_send, request_recv;
MPI_Status status;

while (cnt < times) {
    cnt += 1;

    MPI_Isend(&msg, 1, MPI_INT, next_locality, cnt, MPI_COMM_WORLD,
            &request_send);
    MPI_Irecv(&recv_msg, 1, MPI_INT, next_locality, cnt, MPI_COMM_WORLD,
            &request_recv);

    MPI_Wait(&request_send, &status);
    MPI_Wait(&request_recv, &status);

    std::cout << "Time: " << cnt << ", Locality " << this_locality
            << " received msg: " << recv_msg << "\n";

    recv_msg += 10;
    msg = recv_msg;
}

MPI_Finalize();
return 0;
```

(continues on next page)

(continued from previous page)

```
}
```

HPX equivalent:

```
#include <hpx/config.hpp>

#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/algorithm.hpp>
#include <hpx/hpx_init.hpp>
#include <hpx/modules/collectives.hpp>

#include <cstddef>
#include <cstdint>
#include <iostream>
#include <utility>
#include <vector>

using namespace hpx::collectives;

constexpr char const* channel_communicator_name =
    "/example/channel_communicator/";

// the number of times
constexpr int times = 2;

int hpx_main()
{
    std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
    std::uint32_t this_locality = hpx::get_locality_id();

    // allocate channel communicator
    // NOTE: The communicator object must be kept alive until all
    // participating sites have successfully connected. Destroying it
    // prematurely may cause other sites to hang. Consider using a barrier
    // after creation if the communicator would otherwise go out of scope.
    auto comm = create_channel_communicator(hpx::launch::sync,
        channel_communicator_name, num_sites_arg(num_localities),
        this_site_arg(this_locality));

    std::uint32_t next_locality = (this_locality + 1) % num_localities;
    std::vector<int> msg_vec = {0, 1};

    int cnt = 0;
    int msg = msg_vec[this_locality];

    // send values to another locality
    auto setf = set(comm, that_site_arg(next_locality), msg, tag_arg(cnt));
    auto got_msg = get<int>(comm, that_site_arg(next_locality), tag_arg(cnt));

    setf.get();

    while (cnt < times)
```

(continues on next page)

(continued from previous page)

```
    {
        cnt += 1;

        auto done_msg = got_msg.then([&](auto&& f) {
            int rec_msg = f.get();
            std::cout << "Time: " << cnt << ", Locality " << this_locality
                      << " received msg: " << rec_msg << "\n";

            // change msg by adding 10
            rec_msg += 10;

            // start next round
            setf =
                set(comm, that_site_arg(next_locality), rec_msg, tag_arg(cnt));
            got_msg =
                get<int>(comm, that_site_arg(next_locality), tag_arg(cnt));
            setf.get();
        });

        done_msg.get();
    }

    return hpx::finalize();
}
#endif

int main(int argc, char* argv[])
{
#if !defined(HPX_COMPUTE_DEVICE_CODE)
    hpx::init_params params;
    params.cfg = {"--hpx:run-hpx-main"};
    return hpx::init(argc, argv, params);
#else
    (void) argc;
    (void) argv;
    return 0;
#endif
}
```

To perform message passing between different processes in *HPX* we can use a channel communicator. To understand this example, let's focus on the *hpx_main()* function:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- *create_channel_communicator* function is used to create a channel to serve the communication. This function takes several arguments, including the launch policy (*hpx::launch::sync*), the name of the communicator (*channel_communicator_name*), the number of localities, and the ID of the current locality.
- The communication follows a ring pattern, where each process (or locality) sends a message to its neighbor in a circular manner. This means that the messages circulate around the localities, ensuring that the communication wraps around when reaching the end of the locality sequence. To achieve this, the *next_locality* variable is calculated as the ID of the next locality in the ring.
- The initial values for the communication are set (*msg_vec*, *cnt*, *msg*).

- The *set()* function is called to send the message to the next locality in the ring. The message is sent asynchronously and is associated with a tag (*cnt*).
- The *get()* function is called to receive a message from the next locality. It is also associated with the same tag as the *set()* operation.
- The *setf.get()* call blocks until the message sending operation is complete.
- A continuation is set up using the function *then()* to handle the received message. Inside the continuation:
  - The received message value (*rec_msg*) is retrieved using *f.get()*.
  - The received message is printed to the console and then modified by adding 10.
  - The *set()* and *get()* operations are repeated to send and receive the modified message to the next locality.
  - The *setf.get()* call blocks until the new message sending operation is complete.
- The *done_msg.get()* call blocks until the continuation is complete for the current loop iteration.

Having said that, we conclude to the following table:

MPI_Gather

The following code gathers data from all processes to the root process and verifies the gathered data in the root process.

MPI code:

```
#include <iostream>
#include <mpi.h>
#include <numeric>
#include <vector>

int main(int argc, char *argv[]) {
    MPI_Init(&argc, &argv);

    int num_localities, this_locality;
    MPI_Comm_size(MPI_COMM_WORLD, &num_localities);
    MPI_Comm_rank(MPI_COMM_WORLD, &this_locality);

    std::vector<int> local_data; // Data to be gathered

    if (this_locality == 0) {
        local_data.resize(num_localities); // Resize the vector on the root process
    }

    // Each process calculates its local data value
    int my_data = 42 + this_locality;

    for (std::uint32_t i = 0; i != 10; ++i) {

        // Gather data from all processes to the root process (process 0)
        MPI_Gather(&my_data, 1, MPI_INT, local_data.data(), 1, MPI_INT, 0,
                   MPI_COMM_WORLD);

        // Only the root process (process 0) will print the gathered data
        if (this_locality == 0) {
```

(continues on next page)

(continued from previous page)

```
        std::cout << "Gathered data on the root: ";
        for (int i = 0; i < num_localities; ++i) {
            std::cout << local_data[i] << " ";
        }
        std::cout << std::endl;
        }
    }
    std::cout << std::endl;

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
std::uint32_t this_locality = hpx::get_locality_id();

// test functionality based on immediate local result value
auto gather_direct_client = create_communicator(gather_direct_basename,
    num_sites_arg(num_localities), this_site_arg(this_locality));

for (std::uint32_t i = 0; i != 10; ++i)
{
    if (this_locality == 0)
    {
        hpx::future<std::vector<std::uint32_t>> overall_result =
            gather_here(gather_direct_client, std::uint32_t(42));

        std::vector<std::uint32_t> sol = overall_result.get();
        std::cout << "Gathered data on the root:";

        for (std::size_t j = 0; j != sol.size(); ++j)
        {
            HPX_TEST(j + 42 == sol[j]);
            std::cout << " " << sol[j];
        }
        std::cout << std::endl;
    }
    else
    {
        hpx::future<void> overall_result =
            gather_there(gather_direct_client, this_locality + 42);
        overall_result.get();
    }

}
```

This code will print 10 times the following message:

```
Gathered data on the root: 42 43
```

HPX uses two functions to implement the functionality of *MPI_Gather*: *gather_here* and *gather_there*. *gather_here* is gathering data from all localities to the locality with ID 0 (root locality). *gather_there* allows non-root localities to participate in the gather operation by sending data to the root locality. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *create_communicator()* is used to create a communicator called *gather_direct_client*.
- If the current locality is the root (its ID is equal to 0):
  - The *gather_here* function is used to perform the gather operation. It collects data from all other localities into the *overall_result* future object. The function arguments provide the necessary information, such as the base name for the gather operation (*gather_direct_basename*), the value to be gathered (*value*), the number of localities (*num_localities*), the current locality ID (*this_locality*), and the generation number (related to the gather operation).
  - The *get()* member function of the *overall_result* future is used to retrieve the gathered data.
  - The next *for* loop is used to verify the correctness of the gathered data (*sol*). *HPX_TEST* is a macro provided by the *HPX* testing utilities to perform similar testing with the Standard C++ macro *assert*.
- If the current locality is not the root:
  - The *gather_there* function is used to participate in the gather operation initiated by the root locality. It sends the data (in this case, the value *this_locality + 42*) to the root locality, indicating that it should be included in the gathering.
  - The *get()* member function of the *overall_result* future is used to wait for the gather operation to complete for this locality.

MPI_Scatter

The following code gathers data from all processes to the root process and verifies the gathered data in the root process.

MPI code:

```
#include <iostream>
#include <mpi.h>
#include <vector>

int main(int argc, char *argv[]) {
    MPI_Init(&argc, &argv);

    int num_localities, this_locality;
    MPI_Comm_size(MPI_COMM_WORLD, &num_localities);
    MPI_Comm_rank(MPI_COMM_WORLD, &this_locality);

    int num_localities = num_localities;
    std::vector<int> data(num_localities);

    if (this_locality == 0) {
        // Fill the data vector on the root locality (locality 0)
        for (int i = 0; i < num_localities; ++i) {
        data[i] = 42 + i;
        }
    }
```

(continues on next page)

(continued from previous page)

```
    int local_data; // Variable to store the received data

    // Scatter data from the root locality to all other localities
    MPI_Scatter(&data[0], 1, MPI_INT, &local_data, 1, MPI_INT, 0, MPI_COMM_WORLD);

    // Now, each locality has its own local_data

    // Print the local_data on each locality
    std::cout << "Locality " << this_locality << " received " << local_data
              << std::endl;

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
HPX_TEST_LTE(std::uint32_t(2), num_localities);

std::uint32_t this_locality = hpx::get_locality_id();

auto scatter_direct_client =
    hpx::collectives::create_communicator(scatter_direct_basename,
        num_sites_arg(num_localities), this_site_arg(this_locality));

// test functionality based on immediate local result value
for (std::uint32_t i = 0; i != 10; ++i)
{
    if (this_locality == 0)
    {
        std::vector<std::uint32_t> data(num_localities);
        std::iota(data.begin(), data.end(), 42 + i);

        hpx::future<std::uint32_t> result =
            scatter_to(scatter_direct_client, std::move(data));

        HPX_TEST_EQ(i + 42 + this_locality, result.get());
    }
    else
    {
        hpx::future<std::uint32_t> result =
            scatter_from<std::uint32_t>(scatter_direct_client);

        HPX_TEST_EQ(i + 42 + this_locality, result.get());

        std::cout << "Locality " << this_locality << " received "
                  << i + 42 + this_locality << std::endl;
    }
}
```

For num_localities = 2 and since we run for 10 iterations this code will print the following message:

```
Locality 1 received 43
Locality 1 received 44
Locality 1 received 45
Locality 1 received 46
Locality 1 received 47
Locality 1 received 48
Locality 1 received 49
Locality 1 received 50
Locality 1 received 51
Locality 1 received 52
```

HPX uses two functions to implement the functionality of *MPI_Scatter*: *hpx::scatter_to* and *hpx::scatter_from*. *hpx::scatter_to* is distributing the data from the locality with ID 0 (root locality) to all other localities. *hpx::scatter_from* allows non-root localities to receive the data from the root locality. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *hpx::collectives::create_communicator()* is used to create a communicator called *scatter_direct_client*.
- If the current locality is the root (its ID is equal to 0):
  - The data vector is filled with values ranging from *42 + i* to *42 + i + num_localities - 1*.
  - The *hpx::scatter_to* function is used to perform the scatter operation using the communicator *scatter_direct_client*. This scatters the data vector to other localities and returns a future representing the result.
  - *HPX_TEST_EQ* is a macro provided by the *HPX* testing utilities to test the distributed values.
- If the current locality is not the root:
  - The *hpx::scatter_from* function is used to collect the data by the root locality.
  - *HPX_TEST_EQ* is a macro provided by the *HPX* testing utilities to test the collected values.

MPI_Allgather

The following code gathers data from all processes and sends the data to all processes.

MPI code:

```
#include <cstdint>
#include <iostream>
#include <mpi.h>
#include <vector>

int main(int argc, char **argv) {
    MPI_Init(&argc, &argv);

    int rank, size;
    MPI_Comm_rank(MPI_COMM_WORLD, &rank);
    MPI_Comm_size(MPI_COMM_WORLD, &size);

    // Get the number of MPI processes
    int num_localities = size;
```

(continues on next page)

(continued from previous page)

```
    // Get the MPI process rank
    int here = rank;

    std::uint32_t value = here;

    std::vector<std::uint32_t> r(num_localities);

    // Perform an all-gather operation to gather values from all processes.
    MPI_Allgather(&value, 1, MPI_UINT32_T, r.data(), 1, MPI_UINT32_T,
                  MPI_COMM_WORLD);

    // Print the result.
    std::cout << "Locality " << here << " has values:";
    for (size_t j = 0; j < r.size(); ++j) {
        std::cout << " " << r[j];
    }
    std::cout << std::endl;

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
std::uint32_t here = hpx::get_locality_id();

// test functionality based on immediate local result value
auto all_gather_direct_client =
    create_communicator(all_gather_direct_basename,
        num_sites_arg(num_localities), this_site_arg(here));

std::uint32_t value = here;

hpx::future<std::vector<std::uint32_t>> overall_result =
    all_gather(all_gather_direct_client, value);

std::vector<std::uint32_t> r = overall_result.get();

std::cout << "Locality " << here << " has values:";
for (std::size_t j = 0; j != r.size(); ++j)
{
    std::cout << " " << j;
}
std::cout << std::endl;
```

For num_localities = 2 this code will print the following message:

```
Locality 0 has values: 0 1
Locality 1 has values: 0 1
```

HPX uses the function *all_gather* to implement the functionality of *MPI_Allgather*. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.

- The function *hpx::collectives::create_communicator()* is used to create a communicator called *all_gather_direct_client*.
- The values that the localities exchange with each other are equal to each locality's ID.
- The gather operation is performed using *all_gather*. The result is stored in an *hpx::future* object called *overall_result*, which represents a future result that can be retrieved later when needed.
- The *get()* function waits until the result is available and then stores it in the vector called *r*.

MPI_Allreduce

The following code combines values from all processes and distributes the result back to all processes.

MPI code:

```
#include <cstdint>
#include <iostream>
#include <mpi.h>

int main(int argc, char **argv) {
    MPI_Init(&argc, &argv);

    int rank, size;
    MPI_Comm_rank(MPI_COMM_WORLD, &rank);
    MPI_Comm_size(MPI_COMM_WORLD, &size);

    // Get the number of MPI processes
    int num_localities = size;

    // Get the MPI process rank
    int here = rank;

    // Create a communicator for the all reduce operation.
    MPI_Comm all_reduce_direct_client;
    MPI_Comm_split(MPI_COMM_WORLD, 0, rank, &all_reduce_direct_client);

    // Perform the all reduce operation to calculate the sum of 'here' values.
    std::uint32_t value = here;
    std::uint32_t res = 0;
    MPI_Allreduce(&value, &res, 1, MPI_UINT32_T, MPI_SUM,
                  all_reduce_direct_client);

    std::cout << "Locality " << rank << " has value: " << res << std::endl;

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t const num_localities =
    hpx::get_num_localities(hpx::launch::sync);
```

(continues on next page)

(continued from previous page)

```
std::uint32_t const here = hpx::get_locality_id();

auto const all_reduce_direct_client =
    create_communicator(all_reduce_direct_basename,
        num_sites_arg(num_localities), this_site_arg(here));

std::uint32_t value = here;

hpx::future<std::uint32_t> overall_result =
    all_reduce(all_reduce_direct_client, value, std::plus<std::uint32_t>{});

std::uint32_t res = overall_result.get();
std::cout << "Locality " << here << " has value: " << res << std::endl;
```

For num_localities = 2 this code will print the following message:

```
Locality 0 has value: 1
Locality 1 has value: 1
```

HPX uses the function *all_reduce* to implement the functionality of *MPI_Allreduce*. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *hpx::collectives::create_communicator()* is used to create a communicator called *all_reduce_direct_client*.
- The value of each locality is equal to its ID.
- The reduce operation is performed using *all_reduce*. The result is stored in an *hpx::future* object called *overall_result*, which represents a future result that can be retrieved later when needed.
- The *get()* function waits until the result is available and then stores it in the variable *res*.

MPI_Alltoall

The following code gathers data from and scatters data to all processes.

MPI code:

```
#include <algorithm>
#include <cstdint>
#include <iostream>
#include <mpi.h>
#include <vector>

int main(int argc, char **argv) {
    MPI_Init(&argc, &argv);

    int rank, size;
    MPI_Comm_rank(MPI_COMM_WORLD, &rank);
    MPI_Comm_size(MPI_COMM_WORLD, &size);

    // Get the number of MPI processes
```

(continues on next page)

(continued from previous page)

```
    int num_localities = size;

    // Get the MPI process rank
    int this_locality = rank;

    // Create a communicator for all-to-all operation.
    MPI_Comm all_to_all_direct_client;
    MPI_Comm_split(MPI_COMM_WORLD, 0, rank, &all_to_all_direct_client);

    std::vector<std::uint32_t> values(num_localities);
    std::fill(values.begin(), values.end(), this_locality);

    // Create vectors to store received values.
    std::vector<std::uint32_t> r(num_localities);

    // Perform an all-to-all operation to exchange values with other localities.
    MPI_Alltoall(values.data(), 1, MPI_UINT32_T, r.data(), 1, MPI_UINT32_T,
                 all_to_all_direct_client);

    // Print the results.
    std::cout << "Locality " << this_locality << " has values:";
    for (std::size_t j = 0; j != r.size(); ++j) {
        std::cout << " " << r[j];
    }
    std::cout << std::endl;

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
std::uint32_t this_locality = hpx::get_locality_id();

auto all_to_all_direct_client =
    create_communicator(all_to_all_direct_basename,
        num_sites_arg(num_localities), this_site_arg(this_locality));

std::vector<std::uint32_t> values(num_localities);
std::fill(values.begin(), values.end(), this_locality);

hpx::future<std::vector<std::uint32_t>> overall_result =
    all_to_all(all_to_all_direct_client, std::move(values));

std::vector<std::uint32_t> r = overall_result.get();
std::cout << "Locality " << this_locality << " has values:";

for (std::size_t j = 0; j != r.size(); ++j)
{
    std::cout << " " << r[j];
}
```

(continues on next page)

(continued from previous page)

```
std::cout << std::endl;
```

For num_localities = 2 this code will print the following message:

```
Locality 0 has values: 0 1
Locality 1 has values: 0 1
```

HPX uses the function *all_to_all* to implement the functionality of *MPI_Alltoall*. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *hpx::collectives::create_communicator()* is used to create a communicator called *all_to_all_direct_client*.
- The value each locality sends is equal to its ID.
- The all-to-all operation is performed using *all_to_all*. The result is stored in an *hpx::future* object called *overall_result*, which represents a future result that can be retrieved later when needed.
- The *get()* function waits until the result is available and then stores it in the variable *r*.

MPI_Barrier

The following code shows how barrier is used to synchronize multiple processes.

MPI code:

```
#include <cstdlib>
#include <iostream>
#include <mpi.h>

int main(int argc, char **argv) {
    MPI_Init(&argc, &argv);

    std::size_t iterations = 5;

    int rank, size;
    MPI_Comm_rank(MPI_COMM_WORLD, &rank);
    MPI_Comm_size(MPI_COMM_WORLD, &size);

    for (std::size_t i = 0; i != iterations; ++i) {
        MPI_Barrier(MPI_COMM_WORLD);
        if (rank == 0) {
        std::cout << "Iteration " << i << " completed." << std::endl;
        }
    }

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::size_t iterations = 5;
std::uint32_t this_locality = hpx::get_locality_id();

char const* const barrier_test_name = "/test/barrier/multiple";

hpx::distributed::barrier b(barrier_test_name);
for (std::size_t i = 0; i != iterations; ++i)
{
    b.wait();
    if (this_locality == 0)
    {
        std::cout << "Iteration " << i << " completed." << std::endl;
    }
}
```

This code will print the following message:

```
Iteration 0 completed.
Iteration 1 completed.
Iteration 2 completed.
Iteration 3 completed.
Iteration 4 completed.
```

HPX uses the function *barrier* to implement the functionality of *MPI_Barrier*. In more detail:

- After defining the number of iterations, we use *hpx::get_locality_id()* to get the ID of the current locality.
- *char const* const barrier_test_name = "/test/barrier/multiple"*: This line defines a constant character array as the name of the barrier. This name is used to identify the barrier across different localities. All participating threads that use this name will synchronize at this barrier.
- Using *hpx::distributed::barrier b(barrier_test_name)*, we create an instance of the distributed barrier with the previously defined name. This barrier will be used to synchronize the execution of threads across different localities.
- Running for all the desired iterations, we use *b.wait()* to synchronize the threads. Each thread waits until all other threads also reach this point before any of them can proceed further.

MPI_Bcast

The following code broadcasts data from one process to all other processes.

MPI code:

```
#include <iostream>
#include <mpi.h>

int main(int argc, char *argv[]) {
    MPI_Init(&argc, &argv);

    int num_localities;
    MPI_Comm_size(MPI_COMM_WORLD, &num_localities);

    int here;
```

(continues on next page)

(continued from previous page)

```
    MPI_Comm_rank(MPI_COMM_WORLD, &here);

    int value;

    for (int i = 0; i < 5; ++i) {
        if (here == 0) {
            value = i + 42;
        }

        // Broadcast the value from process 0 to all other processes
        MPI_Bcast(&value, 1, MPI_INT, 0, MPI_COMM_WORLD);

        if (here != 0) {
            std::cout << "Locality " << here << " received " << value << std::endl;
        }

    }

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);

std::uint32_t here = hpx::get_locality_id();

auto broadcast_direct_client =
    create_communicator(broadcast_direct_basename,
        num_sites_arg(num_localities), this_site_arg(here));

// test functionality based on immediate local result value
for (std::uint32_t i = 0; i != 5; ++i)
{
    if (here == 0)
    {
        hpx::future<std::uint32_t> result =
            broadcast_to(broadcast_direct_client, i + 42);

        result.get();
    }
    else
    {
        hpx::future<std::uint32_t> result =
            hpx::collectives::broadcast_from<std::uint32_t>(
                broadcast_direct_client);

        uint32_t r = result.get();

        std::cout << "Locality " << here << " received " << r << std::endl;
    }
```

(continues on next page)

(continued from previous page)

```
}
```

For num_localities = 2 this code will print the following message:

```
Locality 1 received 42
Locality 1 received 43
Locality 1 received 44
Locality 1 received 45
Locality 1 received 46
```

HPX uses two functions to implement the functionality of *MPI_Bcast*: *broadcast_to* and *broadcast_from*. *broadcast_to* is broadcasting the data from the root locality to all other localities. *broadcast_from* allows non-root localities to collect the data sent by the root locality. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *create_communicator()* is used to create a communicator called *broadcast_direct_client*.
- If the current locality is the root (its ID is equal to 0):
  - The *broadcast_to* function is used to perform the broadcast operation using the communicator *broadcast_direct_client*. This sends the data to other localities and returns a future representing the result.
  - The *get()* member function of the *result* future is used to wait for and retrieve the result.
- If the current locality is not the root:
  - The *broadcast_from* function is used to collect the data by the root locality.
  - The *get()* member function of the *result* future is used to wait for the result.

MPI_Exscan

The following code computes the exclusive scan (partial reductions) of data on a collection of processes.

MPI code:

```
#include <iostream>
#include <mpi.h>
#include <numeric>
#include <vector>

int main(int argc, char *argv[]) {
    MPI_Init(&argc, &argv);

    int num_localities;
    MPI_Comm_size(MPI_COMM_WORLD, &num_localities);

    int here;
    MPI_Comm_rank(MPI_COMM_WORLD, &here);

    // Calculate the value for this locality (here)
    int value = here;

    // Perform an exclusive scan
```

(continues on next page)

(continued from previous page)

```
    std::vector<int> result(num_localities);
    MPI_Exscan(&value, &result[0], 1, MPI_INT, MPI_SUM, MPI_COMM_WORLD);

    if (here != 0) {
        int r = result[here - 1]; // Result is in the previous rank's slot

        std::cout << "Locality " << here << " has value " << r << std::endl;
    }

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
std::uint32_t here = hpx::get_locality_id();

auto exclusive_scan_client = create_communicator(exclusive_scan_basename,
    num_sites_arg(num_localities), this_site_arg(here));

// test functionality based on immediate local result value
std::uint32_t value = here;

hpx::future<std::uint32_t> overall_result = exclusive_scan(
    exclusive_scan_client, value, std::plus<std::uint32_t>{});

uint32_t r = overall_result.get();

if (here != 0)
{
    std::cout << "Locality " << here << " has value " << r << std::endl;
}
```

For num_localities = 2 this code will print the following message:

```
Locality 1 has value 0
```

HPX uses the function *exclusive_scan* to implement *MPI_Exscan*. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *create_communicator()* is used to create a communicator called *exclusive_scan_client*.
- The *exclusive_scan* function is used to perform the exclusive scan operation using the communicator *exclusive_scan_client*. *std::plus<std::uint32_t>{}* specifies the binary associative operator to use for the scan. In this case, it's addition for summing values.
- The *get()* member function of the *overall_result* future is used to wait for the result.

MPI_Scan

The following code Computes the inclusive scan (partial reductions) of data on a collection of processes.

MPI code:

```
#include <iostream>
#include <mpi.h>
#include <numeric>
#include <vector>

int main(int argc, char *argv[]) {
    MPI_Init(&argc, &argv);

    int num_localities;
    MPI_Comm_size(MPI_COMM_WORLD, &num_localities);

    int here;
    MPI_Comm_rank(MPI_COMM_WORLD, &here);

    // Calculate the value for this locality (here)
    int value = here;

    std::vector<int> result(num_localities);

    MPI_Scan(&value, &result[0], 1, MPI_INT, MPI_SUM, MPI_COMM_WORLD);

    std::cout << "Locality " << here << " has value " << result[0] << std::endl;

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
std::uint32_t here = hpx::get_locality_id();

auto inclusive_scan_client = create_communicator(inclusive_scan_basename,
    num_sites_arg(num_localities), this_site_arg(here));

std::uint32_t value = here;

hpx::future<std::uint32_t> overall_result = inclusive_scan(
    inclusive_scan_client, value, std::plus<std::uint32_t>{});

uint32_t r = overall_result.get();

std::cout << "Locality " << here << " has value " << r << std::endl;
```

For num_localities = 2 this code will print the following message:

```
Locality 0 has value 0
Locality 1 has value 1
```

HPX uses the function *inclusive_scan* to implement *MPI_Scan*. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *create_communicator()* is used to create a communicator called *inclusive_scan_client*.
- The *inclusive_scan* function is used to perform the exclusive scan operation using the communicator *inclusive_scan_client*. *std::plus<std::uint32_t>{}* specifies the binary associative operator to use for the scan. In this case, it's addition for summing values.
- The *get()* member function of the *overall_result* future is used to wait for the result.

MPI_Reduce

The following code performs a global reduce operation across all processes.

MPI code:

```
#include <iostream>
#include <mpi.h>

int main(int argc, char *argv[]) {
    MPI_Init(&argc, &argv);

    int num_processes;
    MPI_Comm_size(MPI_COMM_WORLD, &num_processes);

    int this_rank;
    MPI_Comm_rank(MPI_COMM_WORLD, &this_rank);

    int value = this_rank;

    int result = 0;

    // Perform the reduction operation
    MPI_Reduce(&value, &result, 1, MPI_INT, MPI_SUM, 0, MPI_COMM_WORLD);

    // Print the result for the root process (process 0)
    if (this_rank == 0) {
        std::cout << "Locality " << this_rank << " has value " << result
                  << std::endl;
    }

    MPI_Finalize();
    return 0;
}
```

HPX equivalent:

```
std::uint32_t num_localities = hpx::get_num_localities(hpx::launch::sync);
std::uint32_t this_locality = hpx::get_locality_id();

auto reduce_direct_client = create_communicator(reduce_direct_basename,
    num_sites_arg(num_localities), this_site_arg(this_locality));
```

(continues on next page)

(continued from previous page)

```
std::uint32_t value = hpx::get_locality_id();

if (this_locality == 0)
{
    hpx::future<std::uint32_t> overall_result = reduce_here(
        reduce_direct_client, value, std::plus<std::uint32_t>{});

    uint32_t r = overall_result.get();

    std::cout << "Locality " << this_locality << " has value " << r
              << std::endl;
}
else
{
    hpx::future<void> overall_result =
        reduce_there(reduce_direct_client, std::move(value));
    overall_result.get();
}
```

This code will print the following message:

```
Locality 0 has value 1
```

HPX uses two functions to implement the functionality of *MPI_Reduce*: *reduce_here* and *reduce_there*. *reduce_here* is gathering data from all localities to the locality with ID 0 (root locality) and then performs the defined reduction operation. *reduce_there* allows non-root localities to participate in the reduction operation by sending data to the root locality. In more detail:

- *hpx::get_num_localities(hpx::launch::sync)* retrieves the number of localities, while *hpx::get_locality_id()* returns the ID of the current locality.
- The function *create_communicator()* is used to create a communicator called *reduce_direct_client*.
- If the current locality is the root (its ID is equal to 0):
  - The *reduce_here* function initiates a reduction operation with addition (*std::plus*) as the reduction operator. The result is stored in *overall_result*.
  - The *get()* member function of the *overall_result* future is used to wait for the result.
- If the current locality is not the root:
  - The *reduce_there* initiates a remote reduction operation.
  - The *get()* member function of the *overall_result* future is used to wait for the remote reduction operation to complete. This is done to ensure synchronization among localities.

Migrating to C++26 reflection-based actions

Starting with HPX 2.0, C++26 static reflection (P2996) can be used to define distributed actions without the verbose macro boilerplate previously required. This section describes how to migrate existing action definitions to the new reflection-based API when building with `HPX_WITH_CXX26_REFLECTION=ON`.

Build requirements

Reflection-based actions require a C++26-capable compiler with reflection support enabled:

- GCC 16.0.1 trunk or later (`stellargroup/gcc_trunk_build_env:1`) with `-freflection -std=c++26`
- Clang 22 with P2996 support (`stellargroup/clang_p2996_build_env:1`) with `-freflection-latest -stdlib=libc++`

Reflection support is auto-detected by HPX's CMake build system via `hpx_check_for_cxx26_reflection()` in `cmake/HPX_PerformCxxFeatureTests.cmake`. No manual flag is required when using a supported compiler — `HPX_HAVE_CXX26_REFLECTION` is set automatically.

Existing code requires no changes

The most important point: **existing code using** `HPX_PLAIN_ACTION`, `HPX_DEFINE_COMPONENT_ACTION`, and related macros requires zero source changes. When `HPX_WITH_CXX26_REFLECTION=ON`, these macros automatically use the reflection-based implementation internally. No `HPX_REGISTER_ACTION` calls are needed — registration is automatic.

```
// This works unchanged with or without reflection enabled.
// When HPX_WITH_CXX26_REFLECTION=ON, it automatically uses
// reflect_action<^^some_function> internally.
HPX_PLAIN_ACTION(some_function, some_action)
```

Explicit migration: plain actions

For new code or explicit migration, use `HPX_ACTION` or `reflect_action` directly:

```
// Before: three-step macro sequence
HPX_PLAIN_ACTION(app::compute, compute_action)
HPX_REGISTER_ACTION_DECLARATION(compute_action)
HPX_REGISTER_ACTION(compute_action)

// After: single line, no registration required
HPX_ACTION(app::compute, compute_action)

// Or equivalently, using the template directly:
using compute_action = hpx::actions::reflect_action<^^app::compute>;
```

Explicit migration: component actions

```
// Before: three-step macro sequence
HPX_DEFINE_COMPONENT_ACTION(server, compute, compute_action)
HPX_REGISTER_ACTION_DECLARATION(compute_action)
HPX_REGISTER_ACTION(compute_action)

// After: single line
HPX_COMPONENT_ACTION(server, compute, compute_action)

// Or equivalently:
using compute_action =
    hpx::actions::reflect_component_action<^^server::compute>;
```

Explicit migration: direct plain actions

```
// Before: three-step macro sequence
HPX_PLAIN_DIRECT_ACTION(app::compute, compute_action)
HPX_REGISTER_ACTION_DECLARATION(compute_action)
HPX_REGISTER_ACTION(compute_action)

// After: single line
HPX_DIRECT_ACTION(app::compute, compute_action)

// Or equivalently, using the template directly:
using compute_action =
    hpx::actions::reflect_direct_action<^^app::compute>;
```

Explicit migration: direct component actions

Direct actions execute without spawning a new HPX thread — locally they run inline on the calling thread, and remotely on the target locality's existing HPX thread. The reflection-based API preserves this behavior:

```
// Before: three-step macro sequence
HPX_DEFINE_COMPONENT_DIRECT_ACTION(server, compute, compute_action)
HPX_REGISTER_ACTION_DECLARATION(compute_action)
HPX_REGISTER_ACTION(compute_action)

// After: single line
HPX_COMPONENT_DIRECT_ACTION(server, compute, compute_action)

// Or equivalently, using the template directly:
using compute_action =
    hpx::actions::reflect_component_direct_action<^^server::compute>;
```

Overloaded functions

Reflection cannot disambiguate overloaded functions. If your action function is overloaded, keep the existing HPX_PLAIN_ACTION macro:

```
// Not supported with reflection (ambiguous):
// using my_action = hpx::actions::reflect_action<^^overloaded_func>;

// Use the existing macro instead:
HPX_PLAIN_ACTION(static_cast<int(*)(int)>(overloaded_func), my_action)
```

Properties available at compile time

Reflection-based action types expose additional compile-time properties:

```
using my_action = hpx::actions::reflect_action<^^app::compute>;

// Number of parameters
static_assert(my_action::arity == 2);

// Function pointer type and value
using fptr = my_action::func_ptr_type;
constexpr auto fp = my_action::func_ptr;
```

2.4.7 Building tests and examples

Tests

To build the tests:

```
$ cmake --build . --target tests
```

To control which tests to run use `ctest`:

- To run single tests, for example a test for `for_loop`:

```
$ ctest --output-on-failure -R tests.unit.modules.algorithms.algorithms.for_loop
```

- To run a whole group of tests:

```
$ ctest --output-on-failure -R tests.unit
```

Examples

- To build (and install) all examples invoke:

```
$ cmake -DHPX_WITH_EXAMPLES=On .
$ make examples
$ make install
```

- To build the hello_world_1 example run:

```
$ make hello_world_1
```

HPX executables end up in the bin directory in your build directory. You can now run hello_world_1 and should see the following output:

```
$ ./bin/hello_world_1
Hello World!
```

You've just run an example which prints Hello World! from the *HPX* runtime. The source for the example is in examples/quickstart/hello_world_1.cpp. The hello_world_distributed example (also available in the examples/quickstart directory) is a distributed hello world program, which is described in *Remote execution with actions*. It provides a gentle introduction to the distributed aspects of *HPX*.

Tip

Most build targets in *HPX* have two names: a simple name and a hierarchical name corresponding to what type of example or test the target is. If you are developing *HPX* it is often helpful to run make help to get a list of available targets. For example, make help | grep hello_world outputs the following:

```
... examples.quickstart.hello_world_2
... hello_world_2
... examples.quickstart.hello_world_1
... hello_world_1
... examples.quickstart.hello_world_distributed
... hello_world_distributed
```

It is also possible to build, for instance, all quickstart examples using make examples.quickstart.

2.4.8 Creating *HPX* projects

Using HPX with pkg-config

How to build *HPX* applications with pkg-config

After you are done installing *HPX*, you should be able to build the following program. It prints Hello World! on the *locality* you run it on.

```
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>
```

(continues on next page)

(continued from previous page)

```
int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Copy the text of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, issue the following commands (where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used while building *HPX*):

```
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o hello_world hello_world.cpp \
   `pkg-config --cflags --libs hpx_application`\
    -lhpx_iostreams -DHPX_APPLICATION_NAME=hello_world
```

Important

When using pkg-config with *HPX*, the pkg-config flags must go after the `-o` flag.

Note

HPX libraries have different names in debug and release mode. If you want to link against a debug *HPX* library, you need to use the `_debug` suffix for the pkg-config name. That means instead of `hpx_application` or `hpx_component`, you will have to use `hpx_application_debug` or `hpx_component_debug` Moreover, all referenced *HPX* components need to have an appended `d` suffix. For example, instead of `-lhpx_iostreams` you will need to specify `-lhpx_iostreamsd`.

Important

If the *HPX* libraries are in a path that is not found by the dynamic linker, you will need to add the path `$HPX_LOCATION/lib` to your linker search path (for example `LD_LIBRARY_PATH` on Linux).

To test the program, type:

```
$ ./hello_world
```

which should print `Hello World!` and exit.

How to build *HPX* components with pkg-config

Let's try a more complex example involving an *HPX* component. An *HPX* component is a class that exposes *HPX* actions. *HPX* components are compiled into dynamically loaded modules called component libraries. Here's the source code:

hello_world_component.cpp

```
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/iostream.hpp>
#include "hello_world_component.hpp"

#include <iostream>

namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}}    // namespace examples::server

HPX_REGISTER_COMPONENT_MODULE()

typedef hpx::components::component<examples::server::hello_world>
    hello_world_type;

HPX_REGISTER_COMPONENT(hello_world_type, hello_world)

HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)
#endif
```

hello_world_component.hpp

```
#pragma once

#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/components.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/serialization.hpp>

#include <utility>

namespace examples { namespace server {
    struct HPX_COMPONENT_EXPORT hello_world
      : hpx::components::component_base<hello_world>
    {
        void invoke();
        HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke)
    };
```

(continues on next page)

(continued from previous page)

```
}}    // namespace examples::server

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)

namespace examples {
    struct hello_world
      : hpx::components::client_base<hello_world, server::hello_world>
    {
        typedef hpx::components::client_base<hello_world, server::hello_world>
            base_type;

        hello_world(hpx::future<hpx::id_type>&& f)
          : base_type(std::move(f))
        {
        }

        hello_world(hpx::id_type&& f)
          : base_type(std::move(f))
        {
        }

        void invoke()
        {
            hpx::async<server::hello_world::invoke_action>(this->get_id())
                .get();
        }
    };
}    // namespace examples

#endif
```

hello_world_client.cpp

```
#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>

#include "hello_world_component.hpp"

int main()
{
    {
        // Create a single instance of the component on this locality.
        examples::hello_world client =
            hpx::new_<examples::hello_world>(hpx::find_here());

        // Invoke the component's action, which will print "Hello World!".
        client.invoke();
    }

    return 0;
```

(continues on next page)

(continued from previous page)

```
}
#endif
```

Copy the three source files above into three files (called `hello_world_component.cpp`, `hello_world_component.hpp` and `hello_world_client.cpp`, respectively).

Now, in the directory where you put the files, run the following command to build the component library. (where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used while building *HPX*):

```
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o libhpx_hello_world.so hello_world_component.cpp \
   `pkg-config --cflags --libs hpx_component` \
    -lhpx_iostreams -DHPX_COMPONENT_NAME=hpx_hello_world
```

Now pick a directory in which to install your *HPX* component libraries. For this example, we'll choose a directory named `my_hpx_libs`:

```
$ mkdir ~/my_hpx_libs
$ mv libhpx_hello_world.so ~/my_hpx_libs
```

Note

HPX libraries have different names in debug and release mode. If you want to link against a debug *HPX* library, you need to use the `_debug` suffix for the pkg-config name. That means instead of `hpx_application` or `hpx_component` you will have to use `hpx_application_debug` or `hpx_component_debug`. Moreover, all referenced *HPX* components need to have a appended `d` suffix, e.g. instead of `-lhpx_iostreams` you will need to specify `-lhpx_iostreamsd`.

Important

If the *HPX* libraries are in a path that is not found by the dynamic linker. You need to add the path `$HPX_LOCATION/lib` to your linker search path (for example `LD_LIBRARY_PATH` on Linux).

Now, to build the application that uses this component (`hello_world_client.cpp`), we do:

```
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o hello_world_client hello_world_client.cpp \
   ``pkg-config --cflags --libs hpx_application``\
    -L${HOME}/my_hpx_libs -lhpx_hello_world -lhpx_iostreams
```

Important

When using pkg-config with *HPX*, the pkg-config flags must go after the `-o` flag.

Finally, you'll need to set your LD_LIBRARY_PATH before you can run the program. To run the program, type:

```
$ export LD_LIBRARY_PATH="$LD_LIBRARY_PATH:$HOME/my_hpx_libs"
$ ./hello_world_client
```

which should print `Hello HPX World!` and exit.

Using *HPX* with CMake-based projects

In addition to the pkg-config support discussed on the previous pages, *HPX* comes with full CMake support. In order to integrate *HPX* into existing or new CMakeLists.txt, you can leverage the find_package[66] command integrated into CMake. Following, is a Hello World component example using CMake.

Let's revisit what we have. We have three files that compose our example application:

- `hello_world_component.hpp`
- `hello_world_component.cpp`
- `hello_world_client.hpp`

The basic structure to include *HPX* into your CMakeLists.txt is shown here:

```
# Require a recent version of cmake
cmake_minimum_required(VERSION 3.18 FATAL_ERROR)

# This project is C++ based.
project(your_app CXX)

# Instruct cmake to find the HPX settings
find_package(HPX)
```

In order to have CMake find *HPX*, it needs to be told where to look for the `HPXConfig.cmake` file that is generated when *HPX* is built or installed. It is used by `find_package(HPX)` to set up all the necessary macros needed to use *HPX* in your project. The ways to achieve this are:

- Set the `HPX_DIR` CMake variable to point to the directory containing the `HPXConfig.cmake` script on the command line when you invoke CMake:

  ```
  $ cmake -DHPX_DIR=$HPX_LOCATION/lib/cmake/HPX ...
  ```

  where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used when building/configuring *HPX*.

- Set the `CMAKE_PREFIX_PATH` variable to the root directory of your *HPX* build or install location on the command line when you invoke CMake:

  ```
  $ cmake -DCMAKE_PREFIX_PATH=$HPX_LOCATION ...
  ```

  The difference between `CMAKE_PREFIX_PATH` and `HPX_DIR` is that CMake will add common postfixes, such as `lib/cmake/<project`, to the `CMAKE_PREFIX_PATH` and search in these locations too. Note that if your project uses *HPX* as well as other CMake-managed projects, the paths to the locations of these multiple projects may be concatenated in the `CMAKE_PREFIX_PATH`.

- The variables above may be set in the CMake GUI or curses ccmake interface instead of the command line.

Additionally, if you wish to require *HPX* for your project, replace the `find_package(HPX)` line with `find_package(HPX REQUIRED)`.

You can check if *HPX* was successfully found with the `HPX_FOUND` CMake variable.

66 https://www.cmake.org/cmake/help/latest/command/find_package.html

Using CMake targets

The recommended way of setting up your targets to use *HPX* is to link to the `HPX::hpx` CMake[67] target:

```
target_link_libraries(hello_world_component PUBLIC HPX::hpx)
```

This requires that you have already created the target like this:

```
add_library(hello_world_component SHARED hello_world_component.cpp)
target_include_directories(hello_world_component PUBLIC ${CMAKE_CURRENT_SOURCE_DIR})
```

When you link your library to the `HPX::hpx` CMake[68] target, you will be able use *HPX* functionality in your library. To use `main()` as the implicit entry point in your application you must additionally link your application to the CMake target `HPX::wrap_main`. This target is automatically linked to executables if you are using the macros described below (*Using macros to create new targets*). See *Re-use the main() function as the main HPX entry point* for more information on implicitly using `main()` as the entry point. If you want the same wrapping behavior without including hpx/hpx_main.hpp[69], link to the `HPX::auto_wrap_main` target instead. This enables the runtime initialization around `main()` unconditionally and is useful for codebases where adding the header to `main.cpp` is impractical

Note

The use of `HPX::auto_wrap_main` is not supported when using the native Windows MSVC toolchain.

If you want to use the facilities exposed by `hpx::runtime_manager` in binaries that were not linked as executables (e.g., in shared libraries), you will need make your cmake target explicitly depend on the `HPX::init` target:

```
add_library(hello_world_component SHARED hello_world_component.cpp)
target_link_libraries(hello_world_component PRIVATE HPX::init)
```

Otherwise you may see compilation errors complaining about the header file `hpx/runtime_manager.hpp` not being found.

Creating a component requires setting two additional compile definitions:

```
target_compile_options(hello_world_component
  HPX_COMPONENT_NAME=hello_world
  HPX_COMPONENT_EXPORTS)
```

Instead of setting these definitions manually you may link to the `HPX::component` target, which sets `HPX_COMPONENT_NAME` to `hpx_<target_name>`, where `<target_name>` is the target name of your library. Note that these definitions should be `PRIVATE` to make sure these definitions are not propagated transitively to dependent targets.

In addition to making your library a component you can make it a plugin. To do so link to the `HPX::plugin` target. Similarly to `HPX::component` this will set `HPX_PLUGIN_NAME` to `hpx_<target_name>`. This definition should also be `PRIVATE`. Unlike regular shared libraries, plugins are loaded at runtime from certain directories and will not be found without additional configuration. Plugins should be installed into a directory containing only plugins. For example, the plugins created by *HPX* itself are installed into the `hpx` subdirectory in the library install directory (typically `lib` or `lib64`). When using the `HPX::plugin` target you need to install your plugins into an appropriate directory. You may also want to set the location of your plugin in the build directory with the `*_OUTPUT_DIRECTORY*` CMake target properties to be able to load the plugins in the build directory. Once you've set the install or output directory of your plugin

[67] https://www.cmake.org
[68] https://www.cmake.org
[69] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/wrap/include/hpx/hpx_main.hpp

you need to tell your executable where to find it at runtime. You can do this either by setting the environment variable HPX_COMPONENT_PATHS or the ini setting hpx.component_paths (see *--hpx:ini*) to the directory containing your plugin.

Using macros to create new targets

In addition to the targets described above, *HPX* provides convenience macros to hide optional boilerplate code that may be useful for your project. The link to the targets described above. We recommend that you use the targets directly whenever possible as they tend to compose better with other targets.

The macro for adding an *HPX* component is add_hpx_component. It can be used in your CMakeLists.txt file like this:

```
# build your application using HPX
add_hpx_component(hello_world
    SOURCES hello_world_component.cpp
    HEADERS hello_world_component.hpp
    COMPONENT_DEPENDENCIES iostreams)
```

Note

add_hpx_component adds a _component suffix to the target name. In the example above, a hello_world_component target will be created.

The available options to add_hpx_component are:

- SOURCES: The source files for that component
- HEADERS: The header files for that component
- DEPENDENCIES: Other libraries or targets this component depends on
- COMPONENT_DEPENDENCIES: The components this component depends on
- PLUGIN: Treats this component as a plugin-able library
- COMPILE_FLAGS: Additional compiler flags
- LINK_FLAGS: Additional linker flags
- FOLDER: Adds the headers and source files to this Source Group folder
- EXCLUDE_FROM_ALL: Do not build this component as part of the all target

After adding the component, the way you add the executable is as follows:

```
# build your application using HPX
add_hpx_executable(hello_world
    SOURCES hello_world_client.cpp
    COMPONENT_DEPENDENCIES hello_world)
```

Note

add_hpx_executable automatically adds a _component suffix to dependencies specified in COMPONENT_DEPENDENCIES, meaning you can directly use the name given when adding a component using add_hpx_component.

When you configure your application, all you need to do is set the `HPX_DIR` variable to point to the installation of *HPX*.

Note

All library targets built with *HPX* are exported and readily available to be used as arguments to target_link_libraries[70] in your targets. The *HPX* include directories are available with the `HPX_INCLUDE_DIRS` CMake variable.

Using the *HPX* compiler wrapper `hpxcxx`

The `hpxcxx` compiler wrapper helps to compile a *HPX* component, application, or object file, based on the arguments passed to it.

```
$ hpxcxx [--exe=<APPLICATION_NAME> | --comp=<COMPONENT_NAME> | -c] FLAGS FILES
```

The `hpxcxx` command **requires** that either an application or a component is built or `-c` flag is specified. If the build is against a debug build, the `-g` is to be specified while building.

Optional `FLAGS`

- `-l <LIBRARY> | -l<LIBRARY>`: Links `<LIBRARY>` to the build
- `-g`: Specifies that the application or component build is against a debug build
- `-rd`: Sets `release-with-debug-info` option
- `-mr`: Sets `minsize-release` option

All other flags (like `-o OUTPUT_FILE`) are directly passed to the underlying C++ compiler.

Using macros to set up existing targets to use *HPX*

In addition to the `add_hpx_component` and `add_hpx_executable`, you can use the `hpx_setup_target` macro to have an already existing target to be used with the *HPX* libraries:

```
hpx_setup_target(target)
```

Optional parameters are:

- `EXPORT`: Adds it to the CMake export list HPXTargets
- `INSTALL`: Generates an install rule for the target
- `PLUGIN`: Treats this component as a plugin-able library
- `TYPE`: The type can be: EXECUTABLE, LIBRARY or COMPONENT
- `DEPENDENCIES`: Other libraries or targets this component depends on
- `COMPONENT_DEPENDENCIES`: The components this component depends on
- `COMPILE_FLAGS`: Additional compiler flags
- `LINK_FLAGS`: Additional linker flags

[70] https://www.cmake.org/cmake/help/latest/command/target_link_libraries.html

If you do not use CMake, you can still build against *HPX*, but you should refer to the section on *How to build HPX components with pkg-config*.

Note

Since *HPX* relies on dynamic libraries, the dynamic linker needs to know where to look for them. If *HPX* isn't installed into a path that is configured as a linker search path, external projects need to either set RPATH or adapt LD_LIBRARY_PATH to point to where the *HPX* libraries reside. In order to set RPATHs, you can include HPX_SetFullRPATH in your project after all libraries you want to link against have been added. Please also consult the CMake documentation here[71].

Using *HPX* with Makefile

A basic project building with *HPX* is through creating makefiles. The process of creating one can get complex depending upon the use of cmake parameter HPX_WITH_HPX_MAIN (which defaults to ON).

How to build *HPX* applications with makefile

If *HPX* is installed correctly, you should be able to build and run a simple Hello World program. It prints Hello World! on the *locality* you run it on.

```
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Copy the content of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, create a Makefile. Add the following code:

```
CXX=(CXX)  # Add your favourite compiler here or let makefile choose default.

CXXFLAGS=-O3 -std=c++17

Boost_ROOT=/path/to/boost
Hwloc_ROOT=/path/to/hwloc
Tcmalloc_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES=$(HPX_ROOT)/include $(Boost_ROOT)/include $(Hwloc_ROOT)/include

LIBRARY_DIRECTIVES=-L$(HPX_ROOT)/lib $(HPX_ROOT)/lib/libhpx_init.a $(HPX_ROOT)/lib/
↪libhpx.so $(Boost_ROOT)/lib/libboost_atomic-mt.so $(Boost_ROOT)/lib/libboost_
```

(continues on next page)

[71] https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/RPATH-handling

(continued from previous page)

```
↪filesystem-mt.so $(Boost_ROOT)/lib/libboost_program_options-mt.so $(Boost_ROOT)/lib/
↪libboost_regex-mt.so $(Boost_ROOT)/lib/libboost_system-mt.so -lpthread $(Tcmalloc_
↪ROOT)/libtcmalloc_minimal.so $(Hwloc_ROOT)/libhwloc.so -ldl -lrt

LINK_FLAGS=$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main  # should be left empty for HPX_
↪WITH_HPX_MAIN=OFF

hello_world: hello_world.o
   $(CXX) $(CXXFLAGS) -o hello_world hello_world.o $(LIBRARY_DIRECTIVES) $(LINK_FLAGS)

hello_world.o:
   $(CXX) $(CXXFLAGS) -c -o hello_world.o hello_world.cpp $(INCLUDE_DIRECTIVES)
```

Important

`LINK_FLAGS` should be left empty if HPX_WITH_HPX_MAIN is set to OFF. Boost in the above example is build with `--layout=tagged`. Actual Boost flags may vary on your build of Boost.

To build the program, type:

```
$ make
```

A successful build should result in hello_world binary. To test, type:

```
$ ./hello_world
```

How to build *HPX* components with makefile

Let's try a more complex example involving an *HPX* component. An *HPX* component is a class that exposes *HPX* actions. *HPX* components are compiled into dynamically-loaded modules called component libraries. Here's the source code:

hello_world_component.cpp

```
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/iostream.hpp>
#include "hello_world_component.hpp"

#include <iostream>

namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}}    // namespace examples::server

HPX_REGISTER_COMPONENT_MODULE()

```

(continues on next page)

(continued from previous page)

```
typedef hpx::components::component<examples::server::hello_world>
    hello_world_type;

HPX_REGISTER_COMPONENT(hello_world_type, hello_world)

HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)
#endif
```

hello_world_component.hpp

```
#pragma once

#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/components.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/serialization.hpp>

#include <utility>

namespace examples { namespace server {
    struct HPX_COMPONENT_EXPORT hello_world
      : hpx::components::component_base<hello_world>
    {
        void invoke();
        HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke)
    };
}}    // namespace examples::server

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)

namespace examples {
    struct hello_world
      : hpx::components::client_base<hello_world, server::hello_world>
    {
        typedef hpx::components::client_base<hello_world, server::hello_world>
            base_type;

        hello_world(hpx::future<hpx::id_type>&& f)
          : base_type(std::move(f))
        {
        }

        hello_world(hpx::id_type&& f)
          : base_type(std::move(f))
        {
        }

```

(continues on next page)

(continued from previous page)

```
        void invoke()
        {
            hpx::async<server::hello_world::invoke_action>(this->get_id())
                .get();
        }
    };
}    // namespace examples

#endif
```

hello_world_client.cpp

```
#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>

#include "hello_world_component.hpp"

int main()
{
    {
        // Create a single instance of the component on this locality.
        examples::hello_world client =
            hpx::new_<examples::hello_world>(hpx::find_here());

        // Invoke the component's action, which will print "Hello World!".
        client.invoke();
    }

    return 0;
}
#endif
```

Now, in the directory, create a Makefile. Add the following code:

```
CXX=(CXX)  # Add your favourite compiler here or let makefile choose default.

CXXFLAGS=-O3 -std=c++17

Boost_ROOT=/path/to/boost
Hwloc_ROOT=/path/to/hwloc
Tcmalloc_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES=$(HPX_ROOT)/include $(Boost_ROOT)/include $(Hwloc_ROOT)/include

LIBRARY_DIRECTIVES=-L$(HPX_ROOT)/lib $(HPX_ROOT)/lib/libhpx_init.a $(HPX_ROOT)/lib/
↪libhpx.so $(Boost_ROOT)/lib/libboost_atomic-mt.so $(Boost_ROOT)/lib/libboost_
↪filesystem-mt.so $(Boost_ROOT)/lib/libboost_program_options-mt.so $(Boost_ROOT)/lib/
↪libboost_regex-mt.so $(Boost_ROOT)/lib/libboost_system-mt.so -lpthread $(Tcmalloc_
↪ROOT)/libtcmalloc_minimal.so $(Hwloc_ROOT)/libhwloc.so -ldl -lrt
```

(continues on next page)

(continued from previous page)

```
LINK_FLAGS=$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main  # should be left empty for HPX_
↪WITH_HPX_MAIN=OFF

hello_world_client: libhpx_hello_world hello_world_client.o
  $(CXX) $(CXXFLAGS) -o hello_world_client $(LIBRARY_DIRECTIVES) libhpx_hello_world
↪$(LINK_FLAGS)

hello_world_client.o: hello_world_client.cpp
  $(CXX) $(CXXFLAGS) -o hello_world_client.o hello_world_client.cpp $(INCLUDE_DIRECTIVES)

libhpx_hello_world: hello_world_component.o
  $(CXX) $(CXXFLAGS) -o libhpx_hello_world hello_world_component.o $(LIBRARY_DIRECTIVES)

hello_world_component.o: hello_world_component.cpp
  $(CXX) $(CXXFLAGS) -c -o hello_world_component.o hello_world_component.cpp $(INCLUDE_
↪DIRECTIVES)
```

To build the program, type:

```
$ make
```

A successful build should result in hello_world binary. To test, type:

```
$ ./hello_world
```

Note

Due to high variations in CMake flags and library dependencies, it is recommended to build *HPX* applications and components with pkg-config or CMakeLists.txt. Writing Makefile may result in broken builds if due care is not taken. pkg-config files and CMake systems are configured with CMake build of *HPX*. Hence, they are stable when used together and provide better support overall.

2.4.9 Starting the *HPX* runtime

In order to write an application that uses services from the *HPX* runtime system, you need to initialize the *HPX* library by inserting certain calls into the code of your application. Depending on your use case, this can be done in 3 different ways:

- *Minimally invasive*: Re-use the `main()` function as the main *HPX* entry point.
- *Balanced use case*: Supply your own main *HPX* entry point while blocking the main thread.
- *Most flexibility*: Supply your own main *HPX* entry point while avoiding blocking the main thread.
- *Suspend and resume*: As above but suspend and resume the *HPX* runtime to allow for other runtimes to be used.

Re-use the `main()` function as the main *HPX* entry point

This method is the least intrusive to your code. However, it provides you with the smallest flexibility in terms of initializing the *HPX* runtime system. The following code snippet shows what a minimal *HPX* application using this technique looks like:

```
#include <hpx/hpx_main.hpp>

int main(int argc, char* argv[])
{
    return 0;
}
```

The only change to your code you have to make is to include the file `hpx/hpx_main.hpp`. In this case the function `main()` will be invoked as the first *HPX* thread of the application. The runtime system will be initialized behind the scenes before the function `main()` is executed and will automatically stop after `main()` has returned. For this method to work you must link your application to the CMake[72] target `HPX::wrap_main`. This is done automatically if you are using the provided macros (*Using macros to create new targets*) to set up your application, but must be done explicitly if you are using targets directly (*Using CMake targets*). All *HPX* API functions can be used from within the `main()` function now. If you cannot or do not want to include `hpx/hpx_main.hpp` in `main.cpp`, you can instead link against `HPX::auto_wrap_main`. That target enables the same runtime startup path without needing the header-triggered opt-in.

Note

The use of `HPX::auto_wrap_main` is not supported when using the native Windows MSVC toolchain.

Note

The function `main()` does not need to expect receiving `argc` and `argv` as shown above, but could expose the signature `int main()`. This is consistent with the usually allowed prototypes for the function `main()` in C++ applications.

All command line arguments specific to *HPX* will still be processed by the *HPX* runtime system as usual. However, those command line options will be removed from the list of values passed to `argc/argv` of the function `main()`. The list of values passed to `main()` will hold only the commandline options that are not recognized by the *HPX* runtime system (see the section *HPX Command Line Options* for more details on what options are recognized by *HPX*).

Note

In this mode all one-letter shortcuts that are normally available on the *HPX* command line are disabled (such as `-t` or `-l` see *HPX Command Line Options*). This is done to minimize any possible interaction between the command line options recognized by the *HPX* runtime system and any command line options defined by the application.

The value returned from the function `main()` as shown above will be returned to the operating system as usual.

Important

[72] https://www.cmake.org

To achieve this seamless integration, the header file hpx/hpx_main.hpp defines a macro:

```
#define main hpx_startup::user_main
```

which could result in unexpected behavior.

Important

To achieve this seamless integration, we use different implementations for different operating systems. In case of Linux or macOS, the code present in hpx_wrap.cpp is put into action. We hook into the system function in case of Linux and provide alternate entry point in case of macOS. For other operating systems we rely on a macro:

```
#define main hpx_startup::user_main
```

provided in the header file hpx/hpx_main.hpp. This implementation can result in unexpected behavior.

Caution

We make use of an *override* variable include_libhpx_wrap in the header file hpx/hpx_main.hpp to swiftly choose the function call stack at runtime. Therefore, the header file should *only* be included in the main executable. Including it in the components will result in multiple definition of the variable.

Supply your own main *HPX* entry point while blocking the main thread

With this method you need to provide an explicit main-thread function named hpx_main at global scope. This function will be invoked as the main entry point of your *HPX* application on the console *locality* only (this function will be invoked as the first *HPX* thread of your application). All *HPX* API functions can be used from within this function.

The thread executing the function *hpx::init* will block waiting for the runtime system to exit. The value returned from hpx_main will be returned from *hpx::init* after the runtime system has stopped.

The function *hpx::finalize* has to be called on one of the *HPX* localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking *HPX* has the advantage of the user being able to decide which version of *hpx::init* to call. This allows to pass additional configuration parameters while initializing the *HPX* runtime system.

```
#include <hpx/hpx_init.hpp>

int hpx_main(int argc, char* argv[])
{
    // Any HPX application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run hpx_main as the first HPX thread, and
    // wait for hpx::finalize being called.
    return hpx::init(argc, argv);
}
```

Note

The function `hpx_main` does not need to expect receiving `argc/argv` as shown above, but could expose one of the following signatures:

```
int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);
```

This is consistent with (and extends) the usually allowed prototypes for the function `main()` in C++ applications.

The header file to include for this method of using *HPX* is `hpx/hpx_init.hpp`.

There are many additional overloads of *hpx::init* available, such as the ability to provide your own entry-point function instead of `hpx_main`. Please refer to the function documentation for more details (see: `hpx/hpx_init.hpp`).

Supply your own main *HPX* entry point while avoiding blocking the main thread

With this method you need to provide an explicit main thread function named `hpx_main` at global scope. This function will be invoked as the main entry point of your *HPX* application on the console *locality* only (this function will be invoked as the first *HPX* thread of your application). All *HPX* API functions can be used from within this function.

The thread executing the function *hpx::start* will *not* block waiting for the runtime system to exit, but will return immediately. The function *hpx::finalize* has to be called on one of the *HPX* localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking *HPX* is useful for applications where the main thread is used for special operations, such a GUIs. The function `hpx::stop` can be used to wait for the *HPX* runtime system to exit and should at least be used as the last function called in `main()`. The value returned from `hpx_main` will be returned from `hpx::stop` after the runtime system has stopped.

```
#include <hpx/hpx_start.hpp>

int hpx_main(int argc, char* argv[])
{
    // Any HPX application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run hpx_main.
    hpx::start(argc, argv);

    // ...Execute other code here...

    // Wait for hpx::finalize being called.
    return hpx::stop();
}
```

Note

The function `hpx_main` does not need to expect receiving `argc/argv` as shown above, but could expose one of the following signatures:

```
int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);
```

This is consistent with (and extends) the usually allowed prototypes for the function `main()` in C++ applications.

The header file to include for this method of using *HPX* is `hpx/hpx_start.hpp`.

There are many additional overloads of *hpx::start* available, such as the option for users to provide their own entry point function instead of `hpx_main`. Please refer to the function documentation for more details (see: `hpx/hpx_start.hpp`).

Supply your own explicit startup function as the main *HPX* entry point

There is also a way to specify any function (besides `hpx_main`) to be used as the main entry point for your *HPX* application:

```
#include <hpx/hpx_init.hpp>

int application_entry_point(int argc, char* argv[])
{
    // Any HPX application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run application_entry_point as the first HPX thread,
    // and wait for hpx::finalize being called.
    return hpx::init(&application_entry_point, argc, argv);
}
```

Note

The function supplied to *hpx::init* must have one of the following prototypes:

int application_entry_point(int argc, char* argv[]); int application_entry_point(hpx::program_options::variables_map& vm);

Note

If `nullptr` is used as the function argument, *HPX* will not run any startup function on this locality.

Suspending and resuming the *HPX* runtime

In some applications it is required to combine *HPX* with other runtimes. To support this use case, *HPX* provides two functions: *hpx::suspend* and *hpx::resume*. *hpx::suspend* is a blocking call which will wait for all scheduled tasks to finish executing and then put the thread pool OS threads to sleep. *hpx::resume* simply wakes up the sleeping threads so that they are ready to accept new work. *hpx::suspend* and *hpx::resume* can be found in the header `hpx/hpx_suspend.hpp`.

```
#include <hpx/hpx_start.hpp>
#include <hpx/hpx_suspend.hpp>

int main(int argc, char* argv[])
{
   // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule a function on the HPX runtime
    hpx::post(&my_function, ...);

    // Wait for all tasks to finish, and suspend the HPX runtime
    hpx::suspend();

    // Execute non-HPX code here

    // Resume the HPX runtime
    hpx::resume();

    // Schedule more work on the HPX runtime

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::post([]() { hpx::finalize(); });
    return hpx::stop();
}
```

Note

hpx::suspend does not wait for *hpx::finalize* to be called. Only call *hpx::finalize* when you wish to fully stop the *HPX* runtime.

Warning

***hpx::suspend* only waits for local tasks, i.e. tasks on the**
current locality, to finish executing. When using *hpx::suspend* in a multi-locality scenario the user is responsible for ensuring that any work required from other localities has also finished.

HPX also supports suspending individual thread pools and threads. For details on how to do that, see the documentation for *`hpx::threads::thread_pool_base`*.

Automatically suspending worker threads

The previous method guarantees that the worker threads are suspended when you ask for it and that they stay suspended. An alternative way to achieve the same effect is to tweak how quickly *HPX* suspends its worker threads when they run out of work. The following configuration values make sure that *HPX* idles very quickly:

```
hpx.max_idle_backoff_time = 1000
hpx.max_idle_loop_count = 0
```

They can be set on the command line using `--hpx:ini=hpx.max_idle_backoff_time=1000` and `--hpx:ini=hpx.max_idle_loop_count=0`. See *Launching and configuring HPX applications* for more details on how to set configuration parameters.

After setting idling parameters the previous example could now be written like this instead:

```cpp
#include <hpx/hpx_start.hpp>

int main(int argc, char* argv[])
{

   // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule some functions on the HPX runtime
    // NOTE: run_as_hpx_thread blocks until completion.
    hpx::run_as_hpx_thread(&my_function, ...);
    hpx::run_as_hpx_thread(&my_other_function, ...);

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::post([]() { hpx::finalize(); });
    return hpx::stop();
}
```

In this example each call to `hpx::run_as_hpx_thread` acts as a "parallel region".

Working of `hpx_main.hpp`

In order to initialize *HPX* from `main()`, we make use of linker tricks.

It is implemented differently for different operating systems. The method of implementation is as follows:

- *Linux*: Using linker `--wrap` option.
- *Mac OSX*: Using the linker `-e` option.
- *Windows*: Using `#define main hpx_startup::user_main`

Linux implementation

We make use of the Linux linker `ld`‘s `--wrap` option to wrap the `main()` function. This way any calls to `main()` are redirected to our own implementation of main. It is here that we check for the existence of `hpx_main.hpp` by making use of a shadow variable `include_libhpx_wrap`. The value of this variable determines the function stack at runtime.

The implementation can be found in `libhpx_wrap.a`.

> **Important**
>
> It is necessary that `hpx_main.hpp` be not included more than once. Multiple inclusions can result in multiple definition of `include_libhpx_wrap`.

Mac OSX implementation

Here we make use of yet another linker option `-e` to change the entry point to our custom entry function `initialize_main`. We initialize the *HPX* runtime system from this function and call main from the initialized system. We determine the function stack at runtime by making use of the shadow variable `include_libhpx_wrap`.

The implementation can be found in `libhpx_wrap.a`.

> **Important**
>
> It is necessary that `hpx_main.hpp` be not included more than once. Multiple inclusions can result in multiple definition of `include_libhpx_wrap`.

Windows implementation

We make use of a macro `#define main hpx_startup::user_main` to take care of the initializations.

This implementation could result in unexpected behaviors.

2.4.10 Launching and configuring *HPX* applications

Configuring *HPX* applications

All *HPX* applications can be configured using special command line options and/or using special configuration files. This section describes the available options, the configuration file format, and the algorithm used to locate possible predefined configuration files. Additionally, this section describes the defaults assumed if no external configuration information is supplied.

During startup any *HPX* application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal database holding all configuration properties. This database is used during the execution of the application to configure different aspects of the runtime system.

In addition to the ini files, any application can supply its own configuration files, which will be merged with the configuration database as well. Moreover, the user can specify additional configuration parameters on the command line when executing an application. The *HPX* runtime system will merge all command line configuration options (see the description of the `--hpx:ini`, `--hpx:config`, and `--hpx:app-config` command line options).

The *HPX* ini file format

All *HPX* applications can be configured using a special file format that is similar to the well-known Windows INI file format[73]. This is a structured text format that allows users to group key/value pairs (properties) into sections. The basic element contained in an ini file is the property. Every property has a name and a value, delimited by an equal sign `'='`. The name appears to the left of the equal sign:

```
name=value
```

The value may contain equal signs as only the first `'='` character is interpreted as the delimiter between `name` and `value`. Whitespace before the name, after the value and immediately before and after the delimiting equal sign is ignored. Whitespace inside the value is retained.

Properties may be grouped into arbitrarily named sections. The section name appears on a line by itself, in square brackets. All properties after the section declaration are associated with that section. There is no explicit "end of section" delimiter; sections end at the next section declaration or the end of the file:

```
[section]
```

In *HPX* sections can be nested. A nested section has a name composed of all section names it is embedded in. The section names are concatenated using a dot `'.'`:

```
[outer_section.inner_section]
```

Here, `inner_section` is logically nested within `outer_section`.

It is possible to use the full section name concatenated with the property name to refer to a particular property. For example, in:

```
[a.b.c]
d = e
```

the property value of `d` can be referred to as `a.b.c.d=e`.

In *HPX* ini files can contain comments. Hash signs `'#'` at the beginning of a line indicate a comment. All characters starting with `'#'` until the end of the line are ignored.

If a property with the same name is reused inside a section, the second occurrence of this property name will override the first occurrence (discard the first value). Duplicate sections simply merge their properties together, as if they occurred contiguously.

In *HPX* ini files a property value `${FOO:default}` will use the environmental variable `FOO` to extract the actual value if it is set and `default` otherwise. No default has to be specified. Therefore, `${FOO}` refers to the environmental variable `FOO`. If `FOO` is not set or empty, the overall expression will evaluate to an empty string. A property value `$[section.key:default]` refers to the value held by the property `section.key` if it exists and `default` otherwise. No default has to be specified. Therefore `$[section.key]` refers to the property `section.key`. If the property `section.key` is not set or empty, the overall expression will evaluate to an empty string.

Note

Any property `$[section.key:default]` is evaluated whenever it is queried and not when the configuration data is initialized. This allows for lazy evaluation and relaxes initialization order of different sections. The only exception are recursive property values, e.g., values referring to the very key they are associated with. Those property values are evaluated at initialization time to avoid infinite recursion.

[73] https://en.wikipedia.org/wiki/INI_file

Built-in default configuration settings

During startup any *HPX* application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal data structure holding all configuration properties.

As a first step the internal configuration database is filled with a set of default configuration properties. Those settings are described on a section by section basis below.

> **Note**
>
> You can print the default configuration settings used for an executable by specifying the command line option *--hpx:dump-config*.

The `system` configuration section

```
[system]
pid = <process-id>
prefix = <current prefix path of core HPX library>
executable = <current prefix path of executable>
```

Property	Description
`system.pid`	This is initialized to store the current OS-process id of the application instance.
`system.prefix`	This is initialized to the base directory *HPX* has been loaded from.
`system.executable_prefix`	This is initialized to the base directory the current executable has been loaded from.

The *HPX* configuration section

```
[hpx]
location = ${HPX_LOCATION:$[system.prefix]}
component_path = $[hpx.location]/lib/hpx:$[system.executable_prefix]/lib/hpx:$[system.
↪executable_prefix]/../lib/hpx
master_ini_path = $[hpx.location]/share/hpx-<version>:$[system.executable_prefix]/share/
↪hpx-<version>:$[system.executable_prefix]/../share/hpx-<version>
ini_path = $[hpx.master_ini_path]/ini
os_threads = 1
cores = all
localities = 1
program_name =
cmd_line =
lock_detection = ${HPX_LOCK_DETECTION:0}
throw_on_held_lock = ${HPX_THROW_ON_HELD_LOCK:1}
minimal_deadlock_detection = <debug>
spinlock_deadlock_detection = <debug>
spinlock_deadlock_detection_limit = ${HPX_SPINLOCK_DEADLOCK_DETECTION_LIMIT:1000000}
max_background_threads = ${HPX_MAX_BACKGROUND_THREADS:$[hpx.os_threads]}
max_idle_loop_count = ${HPX_MAX_IDLE_LOOP_COUNT:<hpx_idle_loop_count_max>}
```

(continues on next page)

(continued from previous page)

```
max_busy_loop_count = ${HPX_MAX_BUSY_LOOP_COUNT:<hpx_busy_loop_count_max>}
max_idle_backoff_time = ${HPX_MAX_IDLE_BACKOFF_TIME:<hpx_idle_backoff_time_max>}
exception_verbosity = ${HPX_EXCEPTION_VERBOSITY:2}
trace_depth = ${HPX_TRACE_DEPTH:20}
handle_signals = ${HPX_HANDLE_SIGNALS:1}
handle_failed_new = ${HPX_HANDLE_FAILED_NEW:1}

[hpx.stacks]
small_size = ${HPX_SMALL_STACK_SIZE:<hpx_small_stack_size>}
medium_size = ${HPX_MEDIUM_STACK_SIZE:<hpx_medium_stack_size>}
large_size = ${HPX_LARGE_STACK_SIZE:<hpx_large_stack_size>}
huge_size = ${HPX_HUGE_STACK_SIZE:<hpx_huge_stack_size>}
use_guard_pages = ${HPX_THREAD_GUARD_PAGE:1}
```

Property	Description
hpx. location	This is initialized to the id of the *locality* this application instance is running on.
hpx. component_	Duplicates are discarded. This property can refer to a list of directories separated by `':'` (Linux, Android, and MacOS) or by `';'` (Windows).
hpx. master_in	This is initialized to the list of default paths of the main hpx.ini configuration files. This property can refer to a list of directories separated by `':'` (Linux, Android, and MacOS) or using `';'` (Windows).
hpx. ini_path	This is initialized to the default path where *HPX* will look for more ini configuration files. This property can refer to a list of directories separated by `':'` (Linux, Android, and MacOS) or using `';'` (Windows).
hpx. os_thread	This setting reflects the number of OS threads used for running *HPX* threads. Defaults to number of detected cores (not hyperthreads/PUs).
hpx. cores	This setting reflects the number of cores used for running *HPX* threads. Defaults to number of detected cores (not hyperthreads/PUs).
hpx. localitie	This setting reflects the number of localities the application is running on. Defaults to `1`.
hpx. program_n	This setting reflects the program name of the application instance. Initialized from the command line `argv[0]`.
hpx. cmd_line	This setting reflects the actual command line used to launch this application instance.
hpx. lock_dete	This setting verifies that no locks are being held while a *HPX* thread is suspended. This setting is applicable only if `HPX_WITH_VERIFY_LOCKS` is set during configuration in CMake.
hpx. throw_on_l	This setting causes an exception if during lock detection at least one lock is being held while a *HPX* thread is suspended. This setting is applicable only if `HPX_WITH_VERIFY_LOCKS` is set during configuration in CMake. This setting has no effect if `hpx.lock_detection=0`.
hpx. minimal_d	This setting enables support for minimal deadlock detection for *HPX* threads. By default this is set to `1` (for Debug builds) or to `0` (for Release, RelWithDebInfo, RelMinSize builds). This setting is effective only if `HPX_WITH_THREAD_DEADLOCK_DETECTION` is set during configuration in CMake.
hpx. spinlock_	This setting verifies that spinlocks don't spin longer than specified using the `hpx.spinlock_deadlock_detection_limit`. This setting is applicable only if `HPX_WITH_SPINLOCK_DEADLOCK_DETECTION` is set during configuration in CMake. By default this is set to `1` (for Debug builds) or to `0` (for Release, RelWithDebInfo, RelMinSize builds).
hpx. spinlock_	This setting specifies the upper limit of the allowed number of spins that spinlocks are allowed to perform. This setting is applicable only if `HPX_WITH_SPINLOCK_DEADLOCK_DETECTION` is set during configuration in CMake. By default this is set to `1000000`.
hpx. max_backg	This setting defines the number of threads in the scheduler, which are used to execute background work. By default this is the same as the number of cores used for the scheduler.
hpx. max_idle_	By default this is defined by the preprocessor constant `HPX_IDLE_LOOP_COUNT_MAX`. This is an internal setting that you should change only if you know exactly what you are doing.
hpx. max_busy_	This setting defines the maximum value of the busy-loop counter in the scheduler. By default this is defined by the preprocessor constant `HPX_BUSY_LOOP_COUNT_MAX`. This is an internal setting that you should change only if you know exactly what you are doing.
hpx. max_idle_l	This setting defines the maximum time (in milliseconds) for the scheduler to sleep after being idle for `hpx.max_idle_loop_count` iterations. This setting is applicable only if `HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF` is set during configuration in CMake[74]. By default this is defined by the preprocessor constant `HPX_IDLE_BACKOFF_TIME_MAX`. This is an internal setting that you should change only if you know exactly what you are doing.
hpx. exception_	This setting defines the verbosity of exceptions. Valid values are integers. A setting of `2` or higher prints all available information. A setting of `1` leaves out the build configuration and environment variables. A setting of `0` or lower prints only the description of the thrown exception and the file name, function, and line number where the exception was thrown. The default value is `2` or the value of the environment variable `HPX_EXCEPTION_VERBOSITY`.
hpx. trace_dep	This setting defines the number of stack-levels printed in generated stack backtraces. This defaults to `20`, but can be changed using the cmake `HPX_WITH_THREAD_BACKTRACE_DEPTH` configuration setting.
hpx. handle_si	This setting defines whether HPX will register signal handlers that will print the configuration information (stack backtrace, system information, etc.) whenever a signal is raised. The default is `1`. Setting this value to `0` can be useful in cases when generating a core-dump on segmentation faults or similar signals is desired.

The hpx.threadpools configuration section

```
[hpx.threadpools]
io_pool_size = ${HPX_NUM_IO_POOL_SIZE:2}
parcel_pool_size = ${HPX_NUM_PARCEL_POOL_SIZE:2}
timer_pool_size = ${HPX_NUM_TIMER_POOL_SIZE:2}
```

Property	Description
hpx.threadpools.io_pool_size	The value of this property defines the number of OS threads created for the internal I/O thread pool.
hpx.threadpools.parcel_pool_size	The value of this property defines the number of OS threads created for the internal parcel thread pool.
hpx.threadpools.timer_pool_size	The value of this property defines the number of OS threads created for the internal timer thread pool.

The hpx.thread_queue configuration section

Important

These are the setting control internal values used by the thread scheduling queues in the *HPX* scheduler. You should not modify these settings unless you know exactly what you are doing.

```
[hpx.thread_queue]
min_tasks_to_steal_pending = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_PENDING:0}
min_tasks_to_steal_staged = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_STAGED:0}
min_add_new_count = ${HPX_THREAD_QUEUE_MIN_ADD_NEW_COUNT:10}
max_add_new_count = ${HPX_THREAD_QUEUE_MAX_ADD_NEW_COUNT:10}
max_delete_count = ${HPX_THREAD_QUEUE_MAX_DELETE_COUNT:1000}
```

Property	Description
hpx.thread_queue.min_tasks_to_steal_pe	The value of this property defines the number of pending *HPX* threads that have to be available before neighboring cores are allowed to steal work. The default is to allow stealing always.
hpx.thread_queue.min_tasks_to_steal_st	The value of this property defines the number of staged *HPX* tasks that need to be available before neighboring cores are allowed to steal work. The default is to allow stealing always.
hpx.thread_queue.min_add_new_count	The value of this property defines the minimal number of tasks to be converted into *HPX* threads whenever the thread queues for a core have run empty.
hpx.thread_queue.max_add_new_count	The value of this property defines the maximal number of tasks to be converted into *HPX* threads whenever the thread queues for a core have run empty.
hpx.thread_queue.max_delete_count	The value of this property defines the number of terminated *HPX* threads to discard during each invocation of the corresponding function.

[74] https://www.cmake.org

The hpx.components configuration section

```
[hpx.components]
load_external = ${HPX_LOAD_EXTERNAL_COMPONENTS:1}
```

Property	Description
hpx.components.load_external	This entry defines whether external components will be loaded on this *locality*. This entry is normally set to 1, and usually there is no need to directly change this value. It is automatically set to 0 for a dedicated *AGAS* server *locality*.

Additionally, the section hpx.components will be populated with the information gathered from all found components. The information loaded for each of the components will contain at least the following properties:

```
[hpx.components.<component_instance_name>]
name = <component_name>
path = <full_path_of_the_component_module>
enabled = $[hpx.components.load_external]
```

Property	Description
hpx.components.<component_instar name	This is the name of a component, usually the same as the second argument to the macro used while registering the component with *HPX_REGISTER_COMPONENT*. Set by the component factory.
hpx.components.<component_instar path	This is either the full path file name of the component module or the directory the component module is located in. In this case, the component module name will be derived from the property hpx.components.<component_instance_name>.name. Set by the component factory.
hpx.components.<component_instar enabled	This setting explicitly enables or disables the component. This is an optional property. *HPX* assumes that the component is enabled if it is not defined.

The value for <component_instance_name> is usually the same as for the corresponding name property. However, generally it can be defined to any arbitrary instance name. It is used to distinguish between different ini sections, one for each component.

The hpx.parcel configuration section

```
[hpx.parcel]
address = ${HPX_PARCEL_SERVER_ADDRESS:<hpx_initial_ip_address>}
port = ${HPX_PARCEL_SERVER_PORT:<hpx_initial_ip_port>}
bootstrap = ${HPX_PARCEL_BOOTSTRAP:<hpx_parcel_bootstrap>}
max_connections = ${HPX_PARCEL_MAX_CONNECTIONS:<hpx_parcel_max_connections>}
max_connections_per_locality = ${HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY:<hpx_parcel_max_
→connections_per_locality>}
max_message_size = ${HPX_PARCEL_MAX_MESSAGE_SIZE:<hpx_parcel_max_message_size>}
max_outbound_message_size = ${HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE:<hpx_parcel_max_
→outbound_message_size>}
array_optimization = ${HPX_PARCEL_ARRAY_OPTIMIZATION:1}
zero_copy_optimization = ${HPX_PARCEL_ZERO_COPY_OPTIMIZATION:$[hpx.parcel.array_
→optimization]}
```

(continues on next page)

(continued from previous page)

```
zero_copy_receive_optimization = ${HPX_PARCEL_ZERO_COPY_RECEIVE_OPTIMIZATION:$[hpx.
↪parcel.array_optimization]}
async_serialization = ${HPX_PARCEL_ASYNC_SERIALIZATION:1}
message_handlers = ${HPX_PARCEL_MESSAGE_HANDLERS:0}
```

Property	Description
`hpx.parcel.address`	This property defines the default IP address to be used for the *parcel* layer to listen to. This IP address will be used as long as no other values are specified (for instance, using the `--hpx:hpx` command line option). The expected format is any valid IP address or domain name format that can be resolved into an IP address. The default depends on the compile time preprocessor constant `HPX_INITIAL_IP_ADDRESS` (`"127.0.0.1"`).
`hpx.parcel.port`	This property defines the default IP port to be used for the *parcel* layer to listen to. This IP port will be used as long as no other values are specified (for instance using the `--hpx:hpx` command line option). The default depends on the compile time preprocessor constant `HPX_INITIAL_IP_PORT` (`7910`).
`hpx.parcel.bootstrap`	This property defines which parcelport type should be used during application bootstrap. The default depends on the compile time preprocessor constant `HPX_PARCEL_BOOTSTRAP` (`"tcp"`).
`hpx.parcel.max_connect`	This property defines how many network connections between different localities are overall kept alive by each *locality*. The default depends on the compile time preprocessor constant `HPX_PARCEL_MAX_CONNECTIONS` (`512`).
`hpx.parcel.max_connect`	This property defines the maximum number of network connections that one *locality* will open to another *locality*. The default depends on the compile time preprocessor constant `HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY` (`4`).
`hpx.parcel.max_message`	This property defines the maximum allowed message size that will be transferrable through the *parcel* layer. The default depends on the compile time preprocessor constant `HPX_PARCEL_MAX_MESSAGE_SIZE` (`1000000000` bytes).
`hpx.parcel.max_outboun`	This property defines the maximum allowed outbound coalesced message size that will be transferrable through the parcel layer. The default depends on the compile time preprocessor constant `HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE` (`1000000` bytes).
`hpx.parcel.array_optim`	This property defines whether this *locality* is allowed to utilize array optimizations during serialization of *parcel* data. The default is 1.
`hpx.parcel.zero_copy_o`	This property defines whether this *locality* is allowed to utilize zero copy optimizations during serialization of *parcel* data. The default is the same value as set for `hpx.parcel.array_optimization`.
`hpx.parcel.zero_copy_r`	This property defines whether this *locality* is allowed to utilize zero copy optimizations on the receiving end during de-serialization of *parcel* data. The default is the same value as set for `hpx.parcel.zero_copy_optimization`.
`hpx.parcel.zero_copy_s`	This property defines the threshold value (in bytes) starting at which the serialization layer will apply zero-copy optimizations for serialized entities. The default value is defined by the preprocessor constant `HPX_ZERO_COPY_SERIALIZATION_THRESHOLD`.
`hpx.parcel.async_seria`	This property defines whether this *locality* is allowed to spawn a new thread for serialization (this is both for encoding and decoding parcels). The default is 1.
`hpx.parcel.message_han`	This property defines whether message handlers are loaded. The default is `0`.
`hpx.parcel.max_backgro`	This property defines how many cores should be used to perform background operations. The default is -1 (all cores).

The following settings relate to the TCP/IP parcelport.

```
[hpx.parcel.tcp]
enable = ${HPX_HAVE_PARCELPORT_TCP:$[hpx.parcel.enabled]}
array_optimization = ${HPX_PARCEL_TCP_ARRAY_OPTIMIZATION:$[hpx.parcel.array_
↪optimization]}
zero_copy_optimization = ${HPX_PARCEL_TCP_ZERO_COPY_OPTIMIZATION:$[hpx.parcel.zero_copy_
↪optimization]}
zero_copy_receive_optimization = ${HPX_PARCEL_TCP_ZERO_COPY_RECEIVE_OPTIMIZATION:$[hpx.
↪parcel.zero_copy_receive_optimization]}
zero_copy_serialization_threshold =  ${HPX_PARCEL_TCP_ZERO_COPY_SERIALIZATION_THRESHOLD:
↪$[hpx.parcel.zero_copy_serialization_threshold]}
async_serialization = ${HPX_PARCEL_TCP_ASYNC_SERIALIZATION:$[hpx.parcel.async_
↪serialization]}
parcel_pool_size = ${HPX_PARCEL_TCP_PARCEL_POOL_SIZE:$[hpx.threadpools.parcel_pool_size]}
max_connections =  ${HPX_PARCEL_TCP_MAX_CONNECTIONS:$[hpx.parcel.max_connections]}
max_connections_per_locality = ${HPX_PARCEL_TCP_MAX_CONNECTIONS_PER_LOCALITY:$[hpx.
↪parcel.max_connections_per_locality]}
max_message_size =  ${HPX_PARCEL_TCP_MAX_MESSAGE_SIZE:$[hpx.parcel.max_message_size]}
max_outbound_message_size =  ${HPX_PARCEL_TCP_MAX_OUTBOUND_MESSAGE_SIZE:$[hpx.parcel.max_
↪outbound_message_size]}
max_background_threads =  ${HPX_PARCEL_TCP_MAX_BACKGROUND_THREADS:$[hpx.parcel.max_
↪background_threads]}
```

Property	Description
hpx.parcel.tcp.enable	Enables the use of the default TCP parcelport. Note that the initial bootstrap of the overall *HPX* application will be performed using the default TCP connections. This parcelport is enabled by default. This will be disabled only if MPI is enabled (see below).
hpx.parcel.tcp.array_optimization	This property defines whether this *locality* is allowed to utilize array optimizations in the TCP/IP parcelport during serialization of parcel data. The default is the same value as set for `hpx.parcel.array_optimization`.
hpx.parcel.tcp.zero_copy_optimiza	This property defines whether this *locality* is allowed to utilize zero copy optimizations during serialization of parcel data. The default is the same value as set for `hpx.parcel.zero_copy_optimization`.
hpx.parcel.tcp.zero_copy_receive_	This property defines whether this *locality* is allowed to utilize zero copy optimizations on the receiving end in the TCP/IP parcelport during de-serialization of *parcel* data. The default is the same value as set for `hpx.parcel.zero_copy_optimization`.
hpx.parcel.tcp.zero_copy_serializ	This property defines the threshold value (in bytes) starting at which the serialization layer will apply zero-copy optimizations for serialized entities. The default is the same value as set for `hpx.parcel.zero_copy_serialization_threshold`.
hpx.parcel.tcp.async_serializatio	This property defines whether this *locality* is allowed to spawn a new thread for serialization in the TCP/IP parcelport (this is both for encoding and decoding parcels). The default is the same value as set for `hpx.parcel.async_serialization`.
hpx.parcel.tcp.parcel_pool_size	The value of this property defines the number of OS threads created for the internal parcel thread pool of the TCP *parcel* port. The default is taken from `hpx.threadpools.parcel_pool_size`.
hpx.parcel.tcp.max_connections	This property defines how many network connections between different localities are overall kept alive by each *locality*. The default is taken from `hpx.parcel.max_connections`.
hpx.parcel.tcp.max_connections_pe	This property defines the maximum number of network connections that one *locality* will open to another *locality*. The default is taken from `hpx.parcel.max_connections_per_locality`.
hpx.parcel.tcp.max_message_size	This property defines the maximum allowed message size that will be transferrable through the *parcel* layer. The default is taken from `hpx.parcel.max_message_size`.
hpx.parcel.tcp.max_outbound_messa	This property defines the maximum allowed outbound coalesced message size that will be transferrable through the *parcel* layer. The default is taken from `hpx.parcel.max_outbound_connections`.
hpx.parcel.tcp.max_background_thr	This property defines how many cores should be used to perform background operations. The default is taken from `hpx.parcel.max_background_threads`.

The following settings relate to the MPI parcelport. These settings take effect only if the compile time constant `HPX_HAVE_PARCELPORT_MPI` is set (the equivalent CMake variable is `HPX_WITH_PARCELPORT_MPI` and has to be set to `ON`).

```
[hpx.parcel.mpi]
enable = ${HPX_HAVE_PARCELPORT_MPI:$[hpx.parcel.enabled]}
env = ${HPX_HAVE_PARCELPORT_MPI_ENV:MV2_COMM_WORLD_RANK,PMI_RANK,OMPI_COMM_WORLD_SIZE,
↪ALPS_APP_PE,PALS_NODEID}
multithreaded = ${HPX_HAVE_PARCELPORT_MPI_MULTITHREADED:1}
rank = <MPI_rank>
processor_name = <MPI_processor_name>
array_optimization = ${HPX_HAVE_PARCEL_MPI_ARRAY_OPTIMIZATION:$[hpx.parcel.array_
↪optimization]}
zero_copy_optimization = ${HPX_HAVE_PARCEL_MPI_ZERO_COPY_OPTIMIZATION:$[hpx.parcel.zero_
↪copy_optimization]}
zero_copy_receive_optimization = ${HPX_HAVE_PARCEL_MPI_ZERO_COPY_RECEIVE_OPTIMIZATION:
↪$[hpx.parcel.zero_copy_receive_optimization]}
```

(continues on next page)

(continued from previous page)

```
zero_copy_serialization_threshold =  ${HPX_PARCEL_MPI_ZERO_COPY_SERIALIZATION_THRESHOLD:
↪$[hpx.parcel.zero_copy_serialization_threshold]}
use_io_pool = ${HPX_HAVE_PARCEL_MPI_USE_IO_POOL:$1}
async_serialization = ${HPX_HAVE_PARCEL_MPI_ASYNC_SERIALIZATION:$[hpx.parcel.async_
↪serialization]}
parcel_pool_size = ${HPX_HAVE_PARCEL_MPI_PARCEL_POOL_SIZE:$[hpx.threadpools.parcel_pool_
↪size]}
max_connections =  ${HPX_HAVE_PARCEL_MPI_MAX_CONNECTIONS:$[hpx.parcel.max_connections]}
max_connections_per_locality = ${HPX_HAVE_PARCEL_MPI_MAX_CONNECTIONS_PER_LOCALITY:$[hpx.
↪parcel.max_connections_per_locality]}
max_message_size =  ${HPX_HAVE_PARCEL_MPI_MAX_MESSAGE_SIZE:$[hpx.parcel.max_message_

↪parcel.max_outbound_message_size]}
max_background_threads =  ${HPX_PARCEL_MPI_MAX_BACKGROUND_THREADS:$[hpx.parcel.max_
↪background_threads]}
```

Property	Description
`hpx.parcel.mpi.enable`	Enables the use of the MPI parcelport. *HPX* tries to detect if the application was started within a parallel MPI environment. If the detection was successful, the MPI parcelport is enabled by default. To explicitly disable the MPI parcelport, set to 0. Note that the initial bootstrap of the overall *HPX* application will be performed using MPI as well.
`hpx.parcel.mpi.env`	This property influences which environment variables (separated by commas) will be analyzed to find out whether the application was invoked by MPI.
`hpx.parcel.mpi.multithreaded`	This property is used to determine what threading mode to use when initializing MPI. If this setting is `0`, *HPX* will initialize MPI with `MPI_THREAD_SINGLE`. If the value is not equal to `0`, *HPX* will initialize MPI with `MPI_THREAD_MULTI`.
`hpx.parcel.mpi.rank`	This property will be initialized to the MPI rank of the *locality*.
`hpx.parcel.mpi.processor_name`	This property will be initialized to the MPI processor name of the *locality*.
`hpx.parcel.mpi.array_optimiza`	This property defines whether this *locality* is allowed to utilize array optimizations in the MPI parcelport during serialization of *parcel* data. The default is the same value as set for `hpx.parcel.array_optimization`.
`hpx.parcel.mpi.zero_copy_opti`	This property defines whether this *locality* is allowed to utilize zero copy optimizations in the MPI parcelport during serialization of parcel data. The default is the same value as set for `hpx.parcel.zero_copy_optimization`.
`hpx.parcel.mpi.zero_copy_rece`	This property defines whether this *locality* is allowed to utilize zero copy optimizations on the receiving end in the MPI parcelport during de-serialization of *parcel* data. The default is the same value as set for `hpx.parcel.zero_copy_optimization`.
`hpx.parcel.mpi.zero_copy_seri`	This property defines the threshold value (in bytes) starting at which the serialization layer will apply zero-copy optimizations for serialized entities. The default is the same value as set for `hpx.parcel.zero_copy_serialization_threshold`.
`hpx.parcel.mpi.use_io_pool`	This property can be set to run the progress thread inside of *HPX* threads instead of a separate thread pool. The default is 1.
`hpx.parcel.mpi.async_serializ`	This property defines whether this *locality* is allowed to spawn a new thread for serialization in the MPI parcelport (this is both for encoding and decoding parcels). The default is the same value as set for `hpx.parcel.async_serialization`.
`hpx.parcel.mpi.parcel_pool_si`	The value of this property defines the number of OS threads created for the internal parcel thread pool of the MPI *parcel* port. The default is taken from `hpx.threadpools.parcel_pool_size`.
`hpx.parcel.mpi.max_connection`	This property defines how many network connections between different localities are overall kept alive by each *locality*. The default is taken from `hpx.parcel.max_connections`.
`hpx.parcel.mpi.max_connection`	This property defines the maximum number of network connections that one *locality* will open to another *locality*. The default is taken from `hpx.parcel.max_connections_per_locality`.
`hpx.parcel.mpi.max_message_si`	This property defines the maximum allowed message size that will be transferrable through the *parcel* layer. The default is taken from `hpx.parcel.max_message_size`.
`hpx.parcel.mpi.max_outbound_m`	This property defines the maximum allowed outbound coalesced message size that will be transferrable through the *parcel* layer. The default is taken from `hpx.parcel.max_outbound_connections`.
`hpx.parcel.mpi.max_background_`	This property defines how many cores should be used to perform background operations. The default is taken from `hpx.parcel.max_background_threads`.

The hpx.agas configuration section

```
[hpx.agas]
address = ${HPX_AGAS_SERVER_ADDRESS:<hpx_initial_ip_address>}
port = ${HPX_AGAS_SERVER_PORT:<hpx_initial_ip_port>}
service_mode = hosted
dedicated_server = 0
max_pending_refcnt_requests = ${HPX_AGAS_MAX_PENDING_REFCNT_REQUESTS:<hpx_initial_agas_max_pending_refcnt_requests>}
use_caching = ${HPX_AGAS_USE_CACHING:1}
use_range_caching = ${HPX_AGAS_USE_RANGE_CACHING:1}
local_cache_size = ${HPX_AGAS_LOCAL_CACHE_SIZE:<hpx_agas_local_cache_size>}
```

Property	Description
`hpx.agas.address`	This property defines the default IP address to be used for the *AGAS* root server. This IP address will be used as long as no other values are specified (for instance, using the `--hpx:agas` command line option). The expected format is any valid IP address or domain name format that can be resolved into an IP address. The default depends on the compile time preprocessor constant `HPX_INITIAL_IP_ADDRESS` (`"127.0.0.1"`).
`hpx.agas.port`	This property defines the default IP port to be used for the *AGAS* root server. This IP port will be used as long as no other values are specified (for instance, using the `--hpx:agas` command line option). The default depends on the compile time preprocessor constant `HPX_INITIAL_IP_PORT` (`7009`).
`hpx.agas.service_m`	This property specifies what type of *AGAS* service is running on this *locality*. Currently, two modes exist. The *locality* that acts as the *AGAS* server runs in `bootstrap` mode. All other localities are in `hosted` mode.
`hpx.agas.dedicated_`	This property specifies whether the *AGAS* server is exclusively running *AGAS* services and not hosting any application components. It is a boolean value. Set to 1 if `--hpx:run-agas-server-only` is present.
`hpx.agas.max_pendi`	This property defines the number of reference counting requests (increments or decrements) to buffer. The default depends on the compile time preprocessor constant `HPX_INITIAL_AGAS_MAX_PENDING_REFCNT_REQUESTS` (`4096`).
`hpx.agas.use_cachi`	This property specifies whether a software address translation cache is used. It is a boolean value. Defaults to 1.
`hpx.agas.use_range_`	This property specifies whether range-based caching is used by the software address translation cache. This property is ignored if *hpx.agas.use_caching* is false. It is a boolean value. Defaults to 1.
`hpx.agas.local_cac`	This property defines the size of the software address translation cache for *AGAS* services. This property is ignored if `hpx.agas.use_caching` is false. Note that if `hpx.agas.use_range_caching` is true, this size will refer to the maximum number of ranges stored in the cache, not the number of entries spanned by the cache. The default depends on the compile time preprocessor constant `HPX_AGAS_LOCAL_CACHE_SIZE` (`4096`).

The `hpx.commandline` configuration section

The following table lists the definition of all pre-defined command line option shortcuts. For more information about commandline options, see the section *HPX Command Line Options*.

```
[hpx.commandline]
aliasing = ${HPX_COMMANDLINE_ALIASING:1}
allow_unknown = ${HPX_COMMANDLINE_ALLOW_UNKNOWN:0}

[hpx.commandline.aliases]
-a = --hpx:agas
-c = --hpx:console
-h = --hpx:help
-I = --hpx:ini
-l = --hpx:localities
-p = --hpx:app-config
-q = --hpx:queuing
-r = --hpx:run-agas-server
-t = --hpx:threads
-v = --hpx:version
-w = --hpx:worker
-x = --hpx:hpx
-0 = --hpx:node=0
-1 = --hpx:node=1
-2 = --hpx:node=2
-3 = --hpx:node=3
-4 = --hpx:node=4
-5 = --hpx:node=5
-6 = --hpx:node=6
-7 = --hpx:node=7
-8 = --hpx:node=8
-9 = --hpx:node=9
```

Note

The short options listed above are disabled by default if the application is built using `#include <hpx/hpx_main.hpp>`. See *Re-use the main() function as the main HPX entry point* for more information. The rationale behind this is that in this case the user's application may handle its own command line options, since *HPX* passes all unknown options to `main()`. Short options like `-t` are prone to create ambiguities regarding what the application will support. Hence, the user should instead rely on the corresponding long options like `--hpx:threads` in such a case.

Property	Description
hpx.commandline.aliasing	Enable command line aliases as defined in the section hpx.commandline.aliases (see below). Defaults to 1.
hpx.commandline.allow_unknown	Allow for unknown command line options to be passed through to hpx_main() Defaults to 0.
hpx.commandline.aliases.-a	On the commandline -a expands to: *--hpx:agas*.
hpx.commandline.aliases.-c	On the commandline -c expands to: *--hpx:console*.
hpx.commandline.aliases.-h	On the commandline -h expands to: *--hpx:help*.
hpx.commandline.aliases.--help	On the commandline --help expands to: *--hpx:help*.
hpx.commandline.aliases.-I	On the commandline -I expands to: *--hpx:ini*.
hpx.commandline.aliases.-l	On the commandline -l expands to: *--hpx:localities*.
hpx.commandline.aliases.-p	On the commandline -p expands to: *--hpx:app-config*.
hpx.commandline.aliases.-q	On the commandline -q expands to: *--hpx:queuing*.
hpx.commandline.aliases.-r	On the commandline -r expands to: *--hpx:run-agas-server*.
hpx.commandline.aliases.-t	On the commandline -t expands to: *--hpx:threads*.
hpx.commandline.aliases.-v	On the commandline -v expands to: *--hpx:version*.
hpx.commandline.aliases.--version	On the commandline --version expands to: *--hpx:version*.
hpx.commandline.aliases.-w	On the commandline -w expands to: *--hpx:worker*.
hpx.commandline.aliases.-x	On the commandline -x expands to: *--hpx:hpx*.
hpx.commandline.aliases.-0	On the commandline -0 expands to: *--hpx:node*=0.
hpx.commandline.aliases.-1	On the commandline -1 expands to: *--hpx:node*=1.
hpx.commandline.aliases.-2	On the commandline -2 expands to: *--hpx:node*=2.
hpx.commandline.aliases.-3	On the commandline -3 expands to: *--hpx:node*=3.
hpx.commandline.aliases.-4	On the commandline -4 expands to: *--hpx:node*=4.
hpx.commandline.aliases.-5	On the commandline -5 expands to: *--hpx:node*=5.
hpx.commandline.aliases.-6	On the commandline -6 expands to: *--hpx:node*=6.
hpx.commandline.aliases.-7	On the commandline -7 expands to: *--hpx:node*=7.
hpx.commandline.aliases.-8	On the commandline -8 expands to: *--hpx:node*=8.
hpx.commandline.aliases.-9	On the commandline -9 expands to: *--hpx:node*=9.

Loading INI files

During startup and after the internal database has been initialized as described in the section *Built-in default configuration settings*, *HPX* will try to locate and load additional ini files to be used as a source for configuration properties. This allows for a wide spectrum of additional customization possibilities by the user and system administrators. The sequence of locations where *HPX* will try loading the ini files is well defined and documented in this section. All ini files found are merged into the internal configuration database. The merge operation itself conforms to the rules as described in the section *The HPX ini file format*.

1. Load all component shared libraries found in the directories specified by the property `hpx.component_path` and retrieve their default configuration information (see section *Loading components* for more details). This property can refer to a list of directories separated by `':'` (Linux, Android, and MacOS) or by `';'` (Windows).
2. Load all files named `hpx.ini` in the directories referenced by the property `hpx.master_ini_path` This property can refer to a list of directories separated by `':'` (Linux, Android, and MacOS) or by `';'` (Windows).
3. Load a file named `.hpx.ini` in the current working directory, e.g., the directory the application was invoked from.
4. Load a file referenced by the environment variable `HPX_INI`. This variable is expected to provide the full path name of the ini configuration file (if any).
5. Load a file named `/etc/hpx.ini`. This lookup is done on non-Windows systems only.
6. Load a file named `.hpx.ini` in the home directory of the current user, e.g., the directory referenced by the environment variable `HOME`.
7. Load a file named `.hpx.ini` in the directory referenced by the environment variable `PWD`.
8. Load the file specified on the command line using the option `--hpx:config`.
9. Load all properties specified on the command line using the option `--hpx:ini`. The properties will be added to the database in the same sequence as they are specified on the command line. The format for those options is, for instance, `--hpx:ini=hpx.default_stack_size=0x4000`. In addition to the explicit command line options, this will set the following properties as implied from other settings:
   - `hpx.parcel.address` and `hpx.parcel.port` as set by `--hpx:hpx`
   - `hpx.agas.address`, `hpx.agas.port` and `hpx.agas.service_mode` as set by `--hpx:agas`
   - `hpx.program_name` and `hpx.cmd_line` will be derived from the actual command line
   - **`hpx.os_threads` and `hpx.localities` as set by**
     `--hpx:threads` and `--hpx:localities`
   - `hpx.runtime_mode` will be derived from any explicit `--hpx:console`, `--hpx:worker`, or `--hpx:connect`, or it will be derived from other settings, such as `--hpx:node =0`, which implies `--hpx:console`.
10. Load files based on the pattern `*.ini` in all directories listed by the property `hpx.ini_path`. All files found during this search will be merged. The property `hpx.ini_path` can hold a list of directories separated by `':'` (on Linux or Mac) or `';'` (on Windows).
11. Load the file specified on the command line using the option `--hpx:app-config`. Note that this file will be merged as the content for a top level section `[application]`.

Note

Any changes made to the configuration database caused by one of the steps will influence the loading process for all subsequent steps. For instance, if one of the ini files loaded changes the property `hpx.ini_path`, this will influence the directories searched in step 9 as described above.

Important

The *HPX* core library will verify that all configuration settings specified on the command line (using the `--hpx:ini` option) will be checked for validity. That means that the library will accept only *known* configuration settings. This is to protect the user from unintentional typos while specifying those settings. This behavior can be overwritten by appending a `'!'` to the configuration key, thus forcing the setting to be entered into the configuration database. For instance: `--hpx:ini=hpx.foo! = 1`

If any of the environment variables or files listed above are not found, the corresponding loading step will be silently skipped.

Loading components

HPX relies on loading application specific components during the runtime of an application. Moreover, *HPX* comes with a set of preinstalled components supporting basic functionalities useful for almost every application. Any component in *HPX* is loaded from a shared library, where any of the shared libraries can contain more than one component type. During startup, *HPX* tries to locate all available components (e.g., their corresponding shared libraries) and creates an internal component registry for later use. This section describes the algorithm used by *HPX* to locate all relevant shared libraries on a system. As described, this algorithm is customizable by the configuration properties loaded from the ini files (see section *Loading INI files*).

Loading components is a two-stage process. First *HPX* tries to locate all component shared libraries, loads those, and generates a default configuration section in the internal configuration database for each component found. For each found component the following information is generated:

```
[hpx.components.<component_instance_name>]
name = <name_of_shared_library>
path = $[component_path]
enabled = $[hpx.components.load_external]
default = 1
```

The values in this section correspond to the expected configuration information for a component as described in the section *Built-in default configuration settings*.

In order to locate component shared libraries, *HPX* will try loading all shared libraries (files with the platform specific extension of a shared library, Linux: `*.so`, Windows: `*.dll`, MacOS: `*.dylib` found in the directory referenced by the ini property `hpx.component_path`).

This first step corresponds to step 1) during the process of filling the internal configuration database with default information as described in section *Loading INI files*.

After all of the configuration information has been loaded, *HPX* performs the second step in terms of loading components. During this step, *HPX* scans all existing configuration sections `[hpx.component.<some_component_instance_name>]` and instantiates a special factory object for each of the successfully located and loaded components. During the application's life time, these factory objects are responsible for creating new and discarding old instances of the component they are associated with. This step is performed after step 11) of the process of filling the internal configuration database with default information as described in section *Loading INI files*.

Application specific component example

This section assumes there is a simple application component that exposes one member function as a component action. The header file `app_server.hpp` declares the C++ type to be exposed as a component. This type has a member function `print_greeting()`, which is exposed as an action `print_greeting_action`. We assume the source files for this example are located in a directory referenced by `$APP_ROOT`:

```
// file: $APP_ROOT/app_server.hpp
#include <hpx/hpx.hpp>
#include <hpx/include/iostreams.hpp>

namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
    };
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action);
```

The corresponding source file contains mainly macro invocations that define the boilerplate code needed for *HPX* to function properly:

```
// file: $APP_ROOT/app_server.cpp
#include "app_server.hpp"

// Define boilerplate required once per component module.
HPX_REGISTER_COMPONENT_MODULE();

// Define factory object associated with our component of type 'app::server'.
HPX_REGISTER_COMPONENT(app::server, app_server);

// Define boilerplate code required for each of the component actions. Use the
// same argument as used for HPX_REGISTER_ACTION_DECLARATION above.
HPX_REGISTER_ACTION(app::server::print_greeting_action);
```

The following gives an example of how the component can be used. Here, one instance of the `app::server` component is created on the current *locality* and the exposed action `print_greeting_action` is invoked using the global id of the newly created instance. Note that no special code is required to delete the component instance after it is not needed anymore. It will be deleted automatically when its last reference goes out of scope (shown in the example below at the closing brace of the block surrounding the code):

```cpp
// file: $APP_ROOT/use_app_server_example.cpp
#include <hpx/hpx_init.hpp>
#include "app_server.hpp"

int hpx_main()
{
    {
        // Create an instance of the app_server component on the current locality.
        hpx::naming:id_type app_server_instance =
            hpx::create_component<app::server>(hpx::find_here());

        // Create an instance of the action 'print_greeting_action'.
        app::server::print_greeting_action print_greeting;

        // Invoke the action 'print_greeting' on the newly created component.
        print_greeting(app_server_instance);
    }
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```

In order to make sure that the application will be able to use the component `app::server`, special configuration information must be passed to *HPX*. The simplest way to allow *HPX* to 'find' the component is to provide special ini configuration files that add the necessary information to the internal configuration database. The component should have a special ini file containing the information specific to the component `app_server`.

```ini
# file: $APP_ROOT/app_server.ini
[hpx.components.app_server]
name = app_server
path = $APP_LOCATION/
```

Here, `$APP_LOCATION` is the directory where the (binary) component shared library is located. *HPX* will attempt to load the shared library from there. The section name `hpx.components.app_server` reflects the instance name of the component (`app_server` is an arbitrary, but unique name). The property value for `hpx.components.app_server.name` should be the same as used for the second argument to the macro *HPX_REGISTER_COMPONENT* above.

Additionally, a file `.hpx.ini`, which could be located in the current working directory (see step 3 as described in the section *Loading INI files*), can be used to add to the ini search path for components:

```ini
# file: $PWD/.hpx.ini
[hpx]
ini_path = $[hpx.ini_path]:$APP_ROOT/
```

This assumes that the above ini file specific to the component is located in the directory `$APP_ROOT`.

Note

It is possible to reference the defined property from inside its value. *HPX* will gracefully use the previous value of `hpx.ini_path` for the reference on the right hand side and assign the overall (now expanded) value to the property.

Logging

HPX uses a sophisticated logging framework, allowing users to follow in detail what operations have been performed inside the *HPX* library in what sequence. This information proves to be very useful for diagnosing problems or just for improving the understanding of what is happening in *HPX* as a consequence of invoking *HPX* API functionality.

Default logging

Enabling default logging is a simple process. The detailed description in the remainder of this section explains different ways to customize the defaults. Default logging can be enabled by using one of the following:

- A command line switch `--hpx:debug-hpx-log`, which will enable logging to the console terminal.
- The command line switch `--hpx:debug-hpx-log=<filename>`, which enables logging to a given file `<filename>`.
- Setting an environment variable `HPX_LOGLEVEL=<loglevel>` while running the *HPX* application. In this case `<loglevel>` should be a number between (or equal to) `1` and `5` where `1` means minimal logging and `5` causes all available messages to be logged. When setting the environment variable, the logs will be written to a file named `hpx.<PID>.lo` in the current working directory, where `<PID>` is the process id of the console instance of the application.

Customizing logging

Generally, logging can be customized either using environment variable settings or using by an ini configuration file. Logging is generated in several categories, each of which can be customized independently. All customizable configuration parameters have reasonable defaults, allowing for the use of logging without any additional configuration effort. The following table lists the available categories.

Table 2.5: Logging categories

Category	Category shortcut	Information to be generated	Environment variable
General	None	Logging information generated by different subsystems of *HPX*, such as thread-manager, parcel layer, LCOs, etc.	`HPX_LOGLEVEL`
AGAS	`AGAS`	Logging output generated by the *AGAS* subsystem	`HPX_AGAS_LOGLEVEL`
Application	`APP`	Logging generated by applications.	`HPX_APP_LOGLEVEL`

By default, all logging output is redirected to the console instance of an application, where it is collected and written to a file, one file for each logging category.

Each logging category can be customized at two levels. The parameters for each are stored in the ini configuration sections `hpx.logging.CATEGORY` and `hpx.logging.console.CATEGORY` (where `CATEGORY` is the category shortcut as listed in the table above). The former influences logging at the source *locality* and the latter modifies the logging behaviour for each of the categories at the console instance of an application.

Levels

All *HPX* logging output has seven different logging levels. These levels can be set explicitly or through environment variables in the main *HPX* ini file as shown below. The logging levels and their associated integral values are shown in the table below, ordered from most verbose to least verbose. By default, all *HPX* logs are set to 0, e.g., all logging output is disabled by default.

Table 2.6: Logging levels

Logging level	Integral value
<debug>	5
<info>	4
<warning>	3
<error>	2
<fatal>	1
No logging	0

Tip

The easiest way to enable logging output is to set the environment variable corresponding to the logging category to an integral value as described in the table above. For instance, setting HPX_LOGLEVEL=5 will enable full logging output for the general category. Please note that the syntax and means of setting environment variables varies between operating systems.

Configuration

Logs will be saved to destinations as configured by the user. By default, logging output is saved on the console instance of an application to hpx.<CATEGORY>.<PID>.lo (where CATEGORY and PID> are placeholders for the category shortcut and the OS process id). The output for the general logging category is saved to hpx.<PID>.log. The default settings for the general logging category are shown here (the syntax is described in the section *The HPX ini file format*):

```
[hpx.logging]
level = ${HPX_LOGLEVEL:0}
destination = ${HPX_LOGDESTINATION:console}
format = ${HPX_LOGFORMAT:(T%locality%/%hpxthread%.%hpxphase%/%hpxcomponent%) P%parentloc
↪%/%hpxparent%.%hpxparentphase% %time%($hh:$mm.$ss.$mili) [%idx%]|\\n}
```

The logging level is taken from the environment variable HPX_LOGLEVEL and defaults to zero, e.g., no logging. The default logging destination is read from the environment variable HPX_LOGDESTINATION On any of the localities it defaults to console, which redirects all generated logging output to the console instance of an application. The following table lists the possible destinations for any logging output. It is possible to specify more than one destination separated by whitespace.

Table 2.7: Logging destinations

Logging destination	Description
file(<filename>)	Directs all output to a file with the given <filename>.
cout	Directs all output to the local standard output of the application instance on this *locality*.
cerr	Directs all output to the local standard error output of the application instance on this *locality*.
console	Directs all output to the console instance of the application. The console instance has its logging destinations configured separately.
android_log	Directs all output to the (Android) system log (available on Android systems only).

The logging format is read from the environment variable `HPX_LOGFORMAT`, and it defaults to a complex format description. This format consists of several placeholder fields (for instance `%locality%`), which will be replaced by concrete values when the logging output is generated. All other information is transferred verbatim to the output. The table below describes the available field placeholders. The separator character `|` separates the logging message prefix formatted as shown and the actual log message which will replace the separator.

Table 2.8: Available field placeholders

Name	Description
locality	The id of the *locality* on which the logging message was generated.
hpxthread	The id of the *HPX* thread generating this logging output.
hpxphase	The phase[76] of the *HPX* thread generating this logging output.
hpxcomponent	The local virtual address of the component which the current *HPX* thread is accessing.
parentloc	The id of the *locality* where the *HPX* thread was running that initiated the current *HPX* thread. The current *HPX* thread is generating this logging output.
hpxparent	The id of the *HPX* thread that initiated the current *HPX* thread. The current *HPX* thread is generating this logging output.
hpxparentphase	The phase of the *HPX* thread when it initiated the current *HPX* thread. The current *HPX* thread is generating this logging output.
time	The time stamp for this logging outputline as generated by the source *locality*.
idx	The sequence number of the logging output line as generated on the source *locality*.
osthread	The sequence number of the OS thread that executes the current *HPX* thread.

Note

Not all of the field placeholder may be expanded for all generated logging output. If no value is available for a particular field, it is replaced with a sequence of `'-'` characters.

Here is an example line from a logging output generated by one of the *HPX* examples (please note that this is generated on a single line, without a line break):

```
(T00000000/0000000002d46f90.01/00000000009ebc10) P--------/0000000002d46f80.02 17:49.37.
↪320 [000000000000004d]
    <info>  [RT] successfully created component {0000000100ff0001, 0000000000030002} of␣
↪type: component_barrier[7(3)]
```

The default settings for the general logging category on the console is shown here:

[76] The phase of a *HPX*-thread counts how often this thread has been activated.

```
[hpx.logging.console]
level = ${HPX_LOGLEVEL:$[hpx.logging.level]}
destination = ${HPX_CONSOLE_LOGDESTINATION:file(hpx.$[system.pid].log)}
format = ${HPX_CONSOLE_LOGFORMAT:|}
```

These settings define how the logging is customized once the logging output is received by the console instance of an application. The logging level is read from the environment variable `HPX_LOGLEVEL` (as set for the console instance of the application). The level defaults to the same values as the corresponding settings in the general logging configuration shown before. The destination on the console instance is set to be a file that's name is generated based on its OS process id. Setting the environment variable `HPX_CONSOLE_LOGDESTINATION` allows customization of the naming scheme for the output file. The logging format is set to leave the original logging output unchanged, as received from one of the localities the application runs on.

HPX Command Line Options

The predefined command line options for any application using *hpx::init* are described in the following subsections.

HPX options (allowed on command line only)

`--hpx:help`
: Print out program usage (default: this message). Possible values: `full` (additionally prints options from components).

`--hpx:version`
: Print out *HPX* version and copyright information.

`--hpx:info`
: Print out *HPX* configuration information.

`--hpx:options-file` `arg`
: Specify a file containing command line options (alternatively: @filepath).

HPX options (additionally allowed in an options file)

`--hpx:worker`
: Run this instance in worker mode.

`--hpx:console`
: Run this instance in console mode.

`--hpx:connect`
: Run this instance in worker mode, but connecting late.

`--hpx:run-agas-server`
: Run *AGAS* server as part of this runtime instance.

`--hpx:run-hpx-main`
: Run the hpx_main function, regardless of *locality* mode.

`--hpx:hpx` `arg`
: The IP address the *HPX* parcelport is listening on, expected format: `address:port` (default: `127.0.0.1:7910`).

--hpx:agas arg

The IP address the *AGAS* root server is running on, expected format: `address:port` (default: `127.0.0.1:7910`).

--hpx:run-agas-server-only

Run only the *AGAS* server.

--hpx:nodefile arg

The file name of a node file to use (list of nodes, one node name per line and core).

--hpx:nodes arg

The (space separated) list of the nodes to use (usually this is extracted from a node file).

--hpx:endnodes

This can be used to end the list of nodes specified using the option *--hpx:nodes*.

--hpx:ifsuffix arg

Suffix to append to host names in order to resolve them to the proper network interconnect.

--hpx:ifprefix arg

Prefix to prepend to host names in order to resolve them to the proper network interconnect.

--hpx:iftransform arg

Sed-style search and replace (`s/search/replace/`) used to transform host names to the proper network interconnect.

--hpx:force_ipv4

Network hostnames will be resolved to ipv4 addresses instead of using the first resolved endpoint. This is especially useful on Windows where the local hostname will resolve to an ipv6 address while remote network hostnames are commonly resolved to ipv4 addresses.

--hpx:localities arg

The number of localities to wait for at application startup (default: `1`).

--hpx:node arg

Number of the node this *locality* is run on (must be unique).

--hpx:ignore-batch-env

Ignore batch environment variables.

--hpx:expect-connecting-localities

This *locality* expects other localities to dynamically connect (this is implied if the number of initial localities is larger than 1).

--hpx:pu-offset

The first processing unit this instance of *HPX* should be run on (default: `0`).

--hpx:pu-step

The step between used processing unit numbers for this instance of *HPX* (default: `1`).

--hpx:threads arg

The number of operating system threads to spawn for this *HPX locality*. Possible values are: numeric values `1`, `2`, `3` and so on, `all` (which spawns one thread per processing unit, includes hyperthreads), or `cores` (which spawns one thread per core) (default: `cores`).

--hpx:cores arg

The number of cores to utilize for this *HPX locality* (default: `all`, i.e., the number of cores is based on the number of threads *--hpx:threads* assuming *--hpx:bind*`=compact`.

--hpx:affinity arg

The affinity domain the OS threads will be confined to, possible values: `pu`, `core`, `numa`, `machine` (default: `pu`).

--hpx:bind arg

he detailed affinity description for the OS threads, see *More details about HPX command line options* for a detailed description of possible values. Do not use with *--hpx:pu-step*, *--hpx:pu-offset* or *--hpx:affinity* options. Implies *--hpx:numa-sensitive* (*--hpx:bind*=none) disables defining thread affinities).

--hpx:use-process-mask

Use the process mask to restrict available hardware resources (implies *--hpx:ignore-batch-env*).

--hpx:print-bind

Print to the console the bit masks calculated from the arguments specified to all *--hpx:bind* options.

--hpx:queuing arg

The queue scheduling policy to use. Options are `local`, `local-priority-fifo`, `local-priority-lifo`, `static`, `static-priority`, `abp-priority-fifo`, `local-workrequesting-fifo`, `local-workrequesting-lifo` `local-workrequesting-mc`, and `abp-priority-lifo` (default: `local-priority-fifo`).

--hpx:high-priority-threads arg

The number of operating system threads maintaining a high priority queue (default: number of OS threads), valid for *--hpx:queuing*=abp-priority, *--hpx:queuing*`static-priority` and *--hpx:queuing*`local-priority` only.

--hpx:numa-sensitive

Makes the scheduler NUMA sensitive.

HPX configuration options

--hpx:app-config arg

Load the specified application configuration (ini) file.

--hpx:config arg

Load the specified *HPX* configuration (ini) file.

--hpx:ini arg

Add a configuration definition to the default runtime configuration.

--hpx:exit

Exit after configuring the runtime.

HPX debugging options

--hpx:list-symbolic-names

List all registered symbolic names after startup.

--hpx:list-component-types

List all dynamic component types after startup.

--hpx:dump-config-initial

Print the initial runtime configuration.

`--hpx:dump-config`

Print the final runtime configuration.

`--hpx:debug-hpx-log [arg]`

Enable all messages on the *HPX* log channel and send all *HPX* logs to the target destination (default: `cout`).

`--hpx:debug-agas-log [arg]`

Enable all messages on the *AGAS* log channel and send all *AGAS* logs to the target destination (default: `cout`).

`--hpx:debug-parcel-log [arg]`

Enable all messages on the parcel transport log channel and send all parcel transport logs to the target destination (default: `cout`).

`--hpx:debug-timing-log [arg]`

Enable all messages on the timing log channel and send all timing logs to the target destination (default: `cout`).

`--hpx:debug-app-log [arg]`

Enable all messages on the application log channel and send all application logs to the target destination (default: `cout`).

`--hpx:debug-clp`

Debug command line processing.

`--hpx:attach-debugger arg`

Wait for a debugger to be attached, possible arg values: `startup` or `exception` (default: `startup`)

HPX options related to performance counters

`--hpx:print-counter`

Print the specified performance counter either repeatedly and/or at the times specified by *--hpx:print-counter-at* (see also option *--hpx:print-counter-interval*).

`--hpx:print-counter-reset`

Print the specified performance counter either repeatedly and/or at the times specified by *--hpx:print-counter-at*. Reset the counter after the value is queried (see also option *--hpx:print-counter-interval*).

`--hpx:print-counter-interval`

Print the performance counter(s) specified with *--hpx:print-counter* repeatedly after the time interval (specified in milliseconds), (default: `0`, which means print once at shutdown).

`--hpx:print-counter-destination`

Print the performance counter(s) specified with *--hpx:print-counter* to the given file (default: `console`).

`--hpx:list-counters`

List the names of all registered performance counters, possible values: `minimal` (prints counter name skeletons), `full` (prints all available counter names).

`--hpx:list-counter-infos`

List the description of all registered performance counters, possible values: `minimal` (prints info for counter name skeletons), `full` (prints all available counter infos).

`--hpx:print-counter-format`

Print the performance counter(s) specified with *--hpx:print-counter*. Possible formats in CSV include a format with a header or without any header (see option *--hpx:no-csv-header*). Possible values: `csv` (prints counter values in CSV format with full names as header), `csv-short` (prints counter values in CSV format with short names provided with *--hpx:print-counter* as *--hpx:print-counter* `shortname,full-countername`

`--hpx:no-csv-header`

Print the performance counter(s) specified with *--hpx:print-counter* and `csv` or `csv-short` format specified with *--hpx:print-counter-format* without header.

`--hpx:print-counter-at` `arg`

Print the performance counter(s) specified with *--hpx:print-counter* (or *--hpx:print-counter-reset*) at the given point in time, possible argument values: `startup`, `shutdown` (default), `noshutdown`.

`--hpx:reset-counters`

Reset all performance counter(s) specified with *--hpx:print-counter* after they have been evaluated.

`--hpx:print-counters-locally`

Each *locality* prints only its own local counters. If this is used with *--hpx:print-counter-destination*=`<file>`, the code will append a `".<locality_id>"` to the file name in order to avoid clashes between localities.

Command line argument shortcuts

Additionally, the following shortcuts are available from every *HPX* application.

Table 2.9: Predefined command line option shortcuts

Shortcut option	Equivalent long option
`-a`	*--hpx:agas*
`-c`	*--hpx:console*
`-h`	*--hpx:help*
`-I`	*--hpx:ini*
`-l`	*--hpx:localities*
`-p`	*--hpx:app-config*
`-q`	*--hpx:queuing*
`-r`	*--hpx:run-agas-server*
`-t`	*--hpx:threads*
`-v`	*--hpx:version*
`-w`	*--hpx:worker*
`-x`	*--hpx:hpx*
`-0`	*--hpx:node*=0
`-1`	*--hpx:node*=1
`-2`	*--hpx:node*=2
`-3`	*--hpx:node*=3
`-4`	*--hpx:node*=4
`-5`	*--hpx:node*=5
`-6`	*--hpx:node*=6
`-7`	*--hpx:node*=7
`-8`	*--hpx:node*=8
`-9`	*--hpx:node*=9

Note

The short options listed above are disabled by default if the application is built using `#include <hpx/hpx_main.hpp>`. See *Re-use the main() function as the main HPX entry point* for more information. The rationale behind this is that in this case the user's application may handle its own command line options, since *HPX* passes all unknown options to `main()`. Short options like `-t` are prone to create ambiguities regarding what the application will support. Hence, the user should instead rely on the corresponding long options like `--hpx:threads` in such a case.

It is possible to define your own shortcut options. In fact, all of the shortcuts listed above are pre-defined using the technique described here. Also, it is possible to redefine any of the pre-defined shortcuts to expand differently as well.

Shortcut options are obtained from the internal configuration database. They are stored as key-value properties in a special properties section named `hpx.commandline`. You can define your own shortcuts by adding the corresponding definitions to one of the ini configuration files as described in the section *Configuring HPX applications*. For instance, in order to define a command line shortcut `--p`, which should expand to `-hpx:print-counter`, the following configuration information needs to be added to one of the ini configuration files:

```
[hpx.commandline.aliases]
--pc = --hpx:print-counter
```

Note

Any arguments for shortcut options passed on the command line are retained and passed as arguments to the corresponding expanded option. For instance, given the definition above, the command line option:

```
--pc=/threads{locality#0/total}/count/cumulative
```

would be expanded to:

```
--hpx:print-counter=/threads{locality#0/total}/count/cumulative
```

Important

Any shortcut option should either start with a single `'-'` or with two `'--'` characters. Shortcuts starting with a single `'-'` are interpreted as short options (i.e., everything after the first character following the `'-'` is treated as the argument). Shortcuts starting with `'--'` are interpreted as long options. No other shortcut formats are supported.

Specifying options for single localities only

For runs involving more than one *locality*, it is sometimes desirable to supply specific command line options to single localities only. When the *HPX* application is launched using a scheduler (like PBS; for more details see section *How to use HPX applications with PBS*), specifying dedicated command line options for single localities may be desirable. For this reason all of the command line options that have the general format `--hpx:<some_key>` can be used in a more general form: `--hpx:<N>:<some_key>`, where `<N>` is the number of the *locality* this command line option will be applied to; all other localities will simply ignore the option. For instance, the following PBS script passes the option `--hpx:pu-offset=4` to the *locality* `'1'` only.

```
#!/bin/bash
#
#PBS -l nodes=2:ppn=4
```

(continues on next page)

(continued from previous page)

```
APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE`
```

Caution

If the first application specific argument (inside `$APP_OPTIONS`) is a non-option (i.e., does not start with a `-` or a `--`), then it must be placed before the option *--hpx:nodes*, which, in this case, should be the last option on the command line.

Alternatively, use the option *--hpx:endnodes* to explicitly mark the end of the list of node names:

```
$ pbsdsh -u $APP_PATH --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE` --
↪hpx:endnodes $APP_OPTIONS
```

More details about *HPX* command line options

This section documents the following list of the command line options in more detail:

- *The command line option --hpx:bind*

The command line option `--hpx:bind`

This command line option allows one to specify the required affinity of the *HPX* worker threads to the underlying processing units. As a result the worker threads will run only on the processing units identified by the corresponding bind specification. The affinity settings are to be specified using *--hpx:bind*=`<BINDINGS>`, where `<BINDINGS>` have to be formatted as described below.

In addition to the syntax described below, one can use *--hpx:bind*=`none` to disable all binding of any threads to a particular core. This is mostly supported for debugging purposes.

The specified affinities refer to specific regions within a machine hardware topology. In order to understand the hardware topology of a particular machine, it may be useful to run the lstopo tool, which is part of Portable Hardware Locality (HWLOC), to see the reported topology tree. Seeing and understanding a topology tree will definitely help in understanding the concepts that are discussed below.

Affinities can be specified using hwloc tuples. Tuples of hwloc *objects* and associated *indexes* can be specified in the form `object:index`, `object:index-index` or `object:index,...,index`. Hwloc objects represent types of mapped items in a topology tree. Possible values for objects are `socket`, `numanode`, `core` and `pu` (processing unit). Indexes are non-negative integers that specify a unique physical object in a topology tree using its logical sequence number.

Chaining multiple tuples together in the more general form `object1:index1[.object2:index2[...]]` is permissible. While the first tuple's object may appear anywhere in the topology, the Nth tuple's object must have a shallower topology depth than the (N+1)th tuple's object. Put simply: as you move right in a tuple chain, objects must go deeper in the topology tree. Indexes specified in chained tuples are relative to the scope of the parent object. For example, `socket:0.core:1` refers to the second core in the first socket (all indices are zero based).

Multiple affinities can be specified using several *--hpx:bind* command line options or by appending several affinities separated by a `';'`. By default, if multiple affinities are specified, they are added.

`"all"` is a special affinity consisting in the entire current topology.

Note

All "names" in an affinity specification, such as `thread`, `socket`, `numanode`, `pu` or `all`, can be abbreviated. Thus, the affinity specification `threads:0-3=socket:0.core:1.pu:1` is fully equivalent to its shortened form `t:0-3=s:0.c:1.p:1`.

Here is a full grammar describing the possible format of mappings:

```
mappings      ::=  distribution | mapping (";" mapping)*
distribution  ::=  "compact" | "scatter" | "balanced" | "numa-balanced"
mapping       ::=  thread_spec "=" pu_specs
thread_spec   ::=  "thread:" range_specs
pu_specs      ::=  pu_spec ("." pu_spec)*
pu_spec       ::=  type ":" range_specs | "~" pu_spec
range_specs   ::=  range_spec ("," range_spec)*
range_spec    ::=  int | int "-" int | "all"
type          ::=  "socket" | "numanode" | "core" | "pu"
```

The following example assumes a system with at least 4 cores, where each core has more than 1 processing unit (hardware threads). Running `hello_world_distributed` with 4 OS threads (on 4 processing units), where each of those threads is bound to the first processing unit of each of the cores, can be achieved by invoking:

```
$ hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0
```

Here, `thread:0-3` specifies the OS threads used to define affinity bindings, and `core:0-3.pu:` defines that for each of the cores (`core:0-3`) only their first processing unit `pu:0` should be used.

Note

The command line option *--hpx:print-bind* can be used to print the bitmasks generated from the affinity mappings as specified with *--hpx:bind*. For instance, on a system with hyperthreading enabled (i.e. 2 processing units per core), the command line:

```
$ hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0 --hpx:print-bind
```

will cause this output to be printed:

```
0: PU L#0(P#0), Core L#0, Socket L#0, Node L#0(P#0)

where each bit in the bitmasks corresponds to a processing unit the listed worker thread will be bound to run on.

The difference between the four possible predefined distribution schemes (`compact`, `scatter`, `balanced` and `numa-balanced`) is best explained with an example. Imagine that we have a system with 4 cores and 4 hardware threads per core on 2 sockets. If we place 8 threads the assignments produced by the `compact`, `scatter`, `balanced` and `numa-balanced` types are shown in the figure below. Notice that `compact` does not fully utilize all the cores in the system. For this reason it is recommended that applications are run using the `scatter` or `balanced`/`numa-balanced` options in most cases.

In addition to the predefined distributions it is possible to restrict the resources used by *HPX* to the process CPU

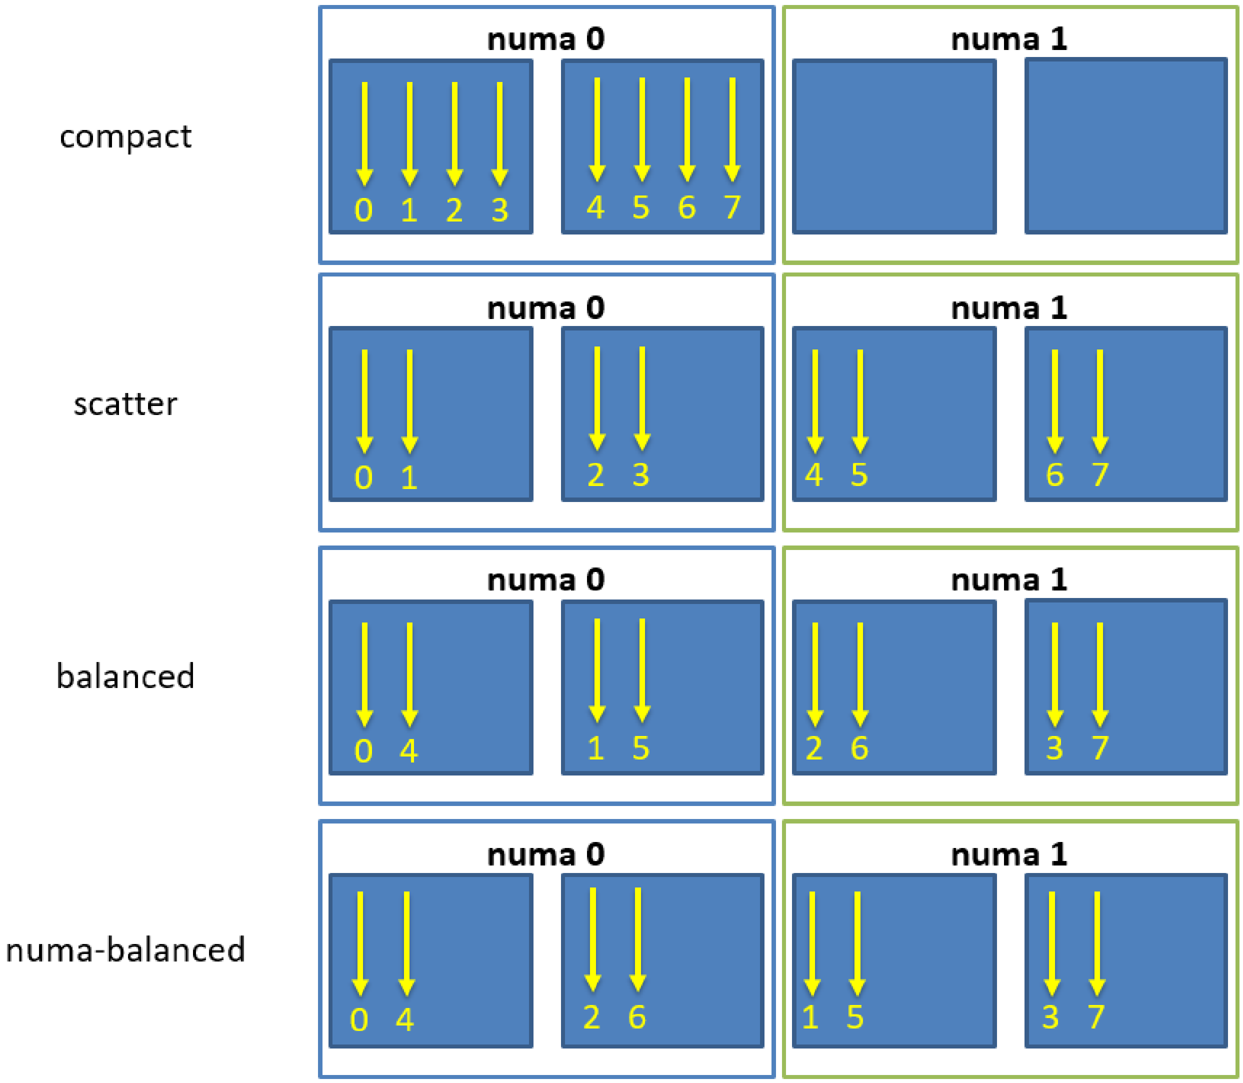

Fig. 2.7: Schematic of thread affinity type distributions.

mask. The CPU mask is typically set by e.g. MPI[75] and batch environments. Using the command line option `--hpx:use-process-mask` makes *HPX* act as if only the processing units in the CPU mask are available for use by *HPX*. The number of threads is automatically determined from the CPU mask. The number of threads can still be changed manually using this option, but only to a number less than or equal to the number of processing units in the CPU mask. The option `--hpx:print-bind` is useful in conjunction with `--hpx:use-process-mask` to make sure threads are placed as expected.

2.4.11 Writing single-node applications

Being a C++ Standard Library for Concurrency and Parallelism, *HPX* implements all of the corresponding facilities as defined by the C++ Standard but also those which are proposed as part of the ongoing C++ standardization process. This section focuses on the features available in *HPX* for parallel and concurrent computation on a single node, although many of the features presented here are also implemented to work in the distributed case.

Synchronization objects

The following objects are providing synchronization for *HPX* applications:

1. *Barrier*
2. *Condition variable*
3. *Latch*
4. *Mutex*
5. *Shared mutex*
6. *Semaphore*
7. *Composable guards*

Barrier

Barriers are used for synchronizing multiple threads. They provide a synchronization point, where all threads must wait until they have all reached the barrier, before they can continue execution. This allows multiple threads to work together to solve a common task, and ensures that no thread starts working on the next task until all threads have completed the current task. This ensures that all threads are in the same state before performing any further operations, leading to a more consistent and accurate computation.

Unlike latches, barriers are reusable: once the participating threads are released from a barrier's synchronization point, they can re-use the same barrier. It is thus useful for managing repeated tasks, or phases of a larger task, that are handled by multiple threads. The code below shows how barriers can be used to synchronize two threads:

```
#include <hpx/barrier.hpp>
#include <hpx/future.hpp>
#include <hpx/init.hpp>

#include <iostream>

int hpx_main()
{
    hpx::barrier b(2);
```

(continues on next page)

[75] https://en.wikipedia.org/wiki/Message_Passing_Interface

(continued from previous page)

```
    hpx::future<void> f1 = hpx::async([&b]() {
        std::cout << "Thread 1 started." << std::endl;
        // Do some computation
        b.arrive_and_wait();
        // Continue with next task
        std::cout << "Thread 1 finished." << std::endl;
    });

    hpx::future<void> f2 = hpx::async([&b]() {
        std::cout << "Thread 2 started." << std::endl;
        // Do some computation
        b.arrive_and_wait();
        // Continue with next task
        std::cout << "Thread 2 finished." << std::endl;
    });

    f1.get();
    f2.get();

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

In this example, two `hpx::future` objects are created, each representing a separate thread of execution. The `wait` function of the `hpx::barrier` object is called by each thread. The threads will wait at the barrier until both have reached it. Once both threads have reached the barrier, they can continue with their next task.

Condition variable

A *condition variable* is a synchronization primitive in *HPX* that allows a thread to wait for a specific condition to be satisfied before continuing execution. It is typically used in conjunction with a mutex or a lock to protect shared data that is being modified by multiple threads. Hence, it blocks one or more threads until another thread both modifies a shared variable (the condition) and notifies the `condition_variable`. The code below shows how two threads modifying the shared variable `data` can be synchronized using the `condition_variable`:

```
#include <hpx/condition_variable.hpp>
#include <hpx/init.hpp>
#include <hpx/mutex.hpp>
#include <hpx/thread.hpp>

#include <iostream>
#include <string>

hpx::condition_variable cv;
hpx::mutex m;
std::string data;
```

(continues on next page)

(continued from previous page)

```
bool ready = false;
bool processed = false;

void worker_thread()
{
    // Wait until the main thread signals that data is ready
    std::unique_lock<hpx::mutex> lk(m);
    cv.wait(lk, [] { return ready; });

    // Access the shared resource
    std::cout << "Worker thread: Processing data...\n";
    data = "Test data after";

    // Send data back to the main thread
    processed = true;
    std::cout << "Worker thread: data processing is complete\n";

    // Manual unlocking is done before notifying, to avoid waking up
    // the waiting thread only to block again
    lk.unlock();
    cv.notify_one();
}

int hpx_main()
{
    hpx::thread worker(worker_thread);

    // Do some work
    std::cout << "Main thread: Preparing data...\n";
    data = "Test data before";
    hpx::this_thread::sleep_for(std::chrono::seconds(1));
    std::cout << "Main thread: Data before processing = " << data << '\n';

    // Signal that data is ready and send data to worker thread
    {
        std::lock_guard<hpx::mutex> lk(m);
        ready = true;
        std::cout << "Main thread: Data is ready...\n";
    }
    cv.notify_one();

    // Wait for the worker thread to finish
    {
        std::unique_lock<hpx::mutex> lk(m);
        cv.wait(lk, [] { return processed; });
    }
    std::cout << "Main thread: Data after processing = " << data << '\n';
    worker.join();

    return hpx::local::finalize();
}
```

(continues on next page)

(continued from previous page)

```
int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

The main thread of the code above starts by creating a worker thread and preparing the shared variable `data`. Once the data is ready, the main thread acquires a lock on the mutex `m` using `std::lock_guard<hpx::mutex> lk(m)` and sets the ready flag to true, then signals the worker thread to start processing by calling `cv.notify_one()`. The `cv.wait()` call in the main thread then blocks until the worker thread signals that processing is complete by setting the `processed` flag.

The worker thread starts by acquiring a lock on the mutex `m` to ensure exclusive access to the shared data. The `cv.wait()` call blocks the thread until the `ready` flag is set by the main thread. Once this is true, the worker thread accesses the shared data resource, processes it, and sets the `processed` flag to indicate completion. The mutex is then unlocked using `lk.unlock()` and the `cv.notify_one()` call signals the main thread to resume execution. Finally, the new `data` is printed by the main thread to the console.

Latch

A *latch* is a downward counter which can be used to synchronize threads. The value of the counter is initialized on creation. Threads may block on the latch until the counter is decremented to zero. There is no possibility to increase or reset the counter, which makes the latch a single-use barrier.

In *HPX*, a latch is implemented as a counting semaphore, which can be initialized with a specific count value and decremented each time a thread reaches the latch. When the count value reaches zero, all waiting threads are unblocked and allowed to continue execution. The code below shows how latch can be used to synchronize 16 threads:

```
std::ptrdiff_t num_threads = 16;

///////////////////////////////////////////////////////////////////////////////
void wait_for_latch(hpx::latch& l)
{
    l.arrive_and_wait();
}

///////////////////////////////////////////////////////////////////////////////
int hpx_main(hpx::program_options::variables_map& vm)
{
    num_threads = vm["num-threads"].as<std::ptrdiff_t>();

    hpx::latch l(num_threads + 1);

    std::vector<hpx::future<void>> results;
    for (std::ptrdiff_t i = 0; i != num_threads; ++i)
        results.push_back(hpx::async(&wait_for_latch, std::ref(l)));

    // Wait for all threads to reach this point.
    l.arrive_and_wait();

    hpx::wait_all(results);

    return hpx::local::finalize();
```

(continues on next page)

(continued from previous page)

```
}
```

In the above code, the `hpx_main` function creates a latch object `l` with a count of `num_threads + 1` and `num_threads` number of threads using `hpx::async`. These threads call the `wait_for_latch` function and pass the reference to the latch object. In the `wait_for_latch` function, the thread calls the `arrive_and_wait` method on the latch, which decrements the count of the latch and causes the thread to wait until the count reaches zero. Finally, the main thread waits for all the threads to arrive at the latch by calling the `arrive_and_wait` method and then waits for all the threads to finish by calling the `hpx::wait_all` method.

Mutex

A *mutex* (short for "mutual exclusion") is a synchronization primitive in *HPX* used to control access to a shared resource, ensuring that only one thread can access it at a time. A mutex is used to protect data structures from race conditions and other synchronization-related issues. When a thread acquires a mutex, other threads that try to access the same resource will be blocked until the mutex is released. The code below shows the basic use of mutexes:

```
#include <hpx/future.hpp>
#include <hpx/init.hpp>
#include <hpx/mutex.hpp>

#include <iostream>

int hpx_main()
{
    hpx::mutex m;

    hpx::future<void> f1 = hpx::async([&m]() {
        std::scoped_lock sl(m);
        std::cout << "Thread 1 acquired the mutex" << std::endl;
    });

    hpx::future<void> f2 = hpx::async([&m]() {
        std::scoped_lock sl(m);
        std::cout << "Thread 2 acquired the mutex" << std::endl;
    });

    hpx::wait_all(f1, f2);

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

In this example, two *HPX* threads created using `hpx::async` are acquiring a `hpx::mutex m`. `std::scoped_lock sl(m)` is used to take ownership of the given mutex `m`. When control leaves the scope in which the `scoped_lock` object was created, the `scoped_lock` is destructed and the mutex is released.

Attention

A common way to acquire and release mutexes is by using the function `m.lock()` before accessing the shared resource, and `m.unlock()` called after the access is complete. However, these functions may lead to deadlocks in case of exception(s). That is, if an exception happens when the mutex is locked then the code that unlocks the mutex will never be executed, the lock will remain held by the thread that acquired it, and other threads will be unable to access the shared resource. This can cause a deadlock if the other threads are also waiting to acquire the same lock. For this reason, we suggest you use `std::scoped_lock`, which prevents this issue by releasing the lock when control leaves the scope in which the `scoped_lock` object was created.

Shared mutex

A *shared mutex* is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. In contrast to other mutex types which facilitate exclusive access, a `shared_mutex` has two levels of access:

- *Exclusive access* prevents any other thread from acquiring the mutex, just as with the normal mutex. It does not matter if the other thread tries to acquire shared or exclusive access.
- *Shared access* allows multiple threads to acquire the mutex, but all of them only in shared mode. Exclusive access is not granted until all of the previous shared holders have returned the mutex (typically, as long as an exclusive request is waiting, new shared ones are queued to be granted after the exclusive access).

Shared mutexes are especially useful when shared data can be safely read by any number of threads simultaneously, but a thread may only write the same data when no other thread is reading or writing at the same time. A typical scenario is a database: The data can be read simultaneously by different threads with no problem. However, modification of the database is critical: if some threads read data while another one is writing, the threads reading may receive inconsistent data. Hence, while a thread is writing, reading should not be allowed. After writing is complete, reads can occur simultaneously again. The code below shows how `shared_mutex` can be used to synchronize reads and writes:

```
int const writers = 3;
int const readers = 3;
int const cycles = 10;

using std::chrono::milliseconds;

int hpx_main()
{
    std::vector<hpx::thread> threads;
    std::atomic<bool> ready(false);
    hpx::shared_mutex stm;

    for (int i = 0; i < writers; ++i)
    {
        threads.emplace_back([&ready, &stm, i] {
            std::mt19937 urng(static_cast<std::uint32_t>(std::time(nullptr)));
            std::uniform_int_distribution<int> dist(1, 1000);

            while (!ready)
            { /*** wait... ***/
            }

            for (int j = 0; j < cycles; ++j)
```

(continues on next page)

(continued from previous page)

```
            {
                // scope of unique_lock
                {
                    std::unique_lock<hpx::shared_mutex> ul(stm);

                    std::cout << "^^^ Writer " << i << " starting..."
                              << std::endl;
                    hpx::this_thread::sleep_for(milliseconds(dist(urng)));
                    std::cout << "vvv Writer " << i << " finished."
                              << std::endl;
                }

                hpx::this_thread::sleep_for(milliseconds(dist(urng)));
            }
        });
    }

    for (int i = 0; i < readers; ++i)
    {
        int k = writers + i;
        threads.emplace_back([&ready, &stm, k, i] {
            HPX_UNUSED(k);
            std::mt19937 urng(static_cast<std::uint32_t>(std::time(nullptr)));
            std::uniform_int_distribution<int> dist(1, 1000);

            while (!ready)
            { /*** wait... ***/
            }

            for (int j = 0; j < cycles; ++j)
            {
                // scope of shared_lock
                {
                    std::shared_lock<hpx::shared_mutex> sl(stm);

                    std::cout << "Reader " << i << " starting..." << std::endl;
                    hpx::this_thread::sleep_for(milliseconds(dist(urng)));
                    std::cout << "Reader " << i << " finished." << std::endl;
                }
                hpx::this_thread::sleep_for(milliseconds(dist(urng)));
            }
        });
    }

    ready = true;
    for (auto& t : threads)
        t.join();

    return hpx::local::finalize();
}
```

The above code creates `writers` and `readers` threads, each of which will perform `cycles` of operations. Both the writer and reader threads use the `hpx::shared_mutex` object `stm` to synchronize access to a shared resource.

- For the writer threads, a `unique_lock` on the shared mutex is acquired before each write operation and is released after control leaves the scope in which the `unique_lock` object was created.
- For the reader threads, a `shared_lock` on the shared mutex is acquired before each read operation and is released after control leaves the scope in which the `shared_lock` object was created.

Before each operation, both the reader and writer threads sleep for a random time period, which is generated using a random number generator. The random time period simulates the processing time of the operation.

Semaphore

Semaphores are a synchronization mechanism used to control concurrent access to a shared resource. The two types of semaphores are:

- counting semaphore: it has a counter that is bigger than zero. The counter is initialized in the constructor. Acquiring the semaphore decreases the counter and releasing the semaphore increases the counter. If a thread tries to acquire the semaphore when the counter is zero, the thread will block until another thread increments the counter by releasing the semaphore. Unlike `hpx::mutex`, an `hpx::counting_semaphore` is not bound to a thread, which means that the acquire and release call of a semaphore can happen on different threads.
- binary semaphore: it is an alias for a `hpx::counting_semaphore<1>`. In this case, the least maximal value is 1. `hpx::binary_semaphore` can be used to implement locks.

```cpp
#include <hpx/init.hpp>
#include <hpx/semaphore.hpp>
#include <hpx/thread.hpp>

#include <iostream>

// initialize the semaphore with a count of 3
hpx::counting_semaphore<> semaphore(3);

void worker()
{
    semaphore.acquire();    // decrement the semaphore's count
    std::cout << "Entering critical section" << std::endl;
    hpx::this_thread::sleep_for(std::chrono::seconds(1));
    semaphore.release();    // increment the semaphore's count
    std::cout << "Exiting critical section" << std::endl;
}

int hpx_main()
{
    hpx::thread t1(worker);
    hpx::thread t2(worker);
    hpx::thread t3(worker);
    hpx::thread t4(worker);
    hpx::thread t5(worker);

    t1.join();
    t2.join();
    t3.join();
    t4.join();
    t5.join();
```

(continues on next page)

(continued from previous page)

```
    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

In this example, the counting semaphore is initialized to the value of 3. This means that up to 3 threads can access the critical section (the section of code inside `the worker()` function) at the same time. When a thread enters the critical section, it acquires the semaphore, which decrements the count, while when it exits the critical section, it releases the semaphore, incrementing thus the count. The `worker()` function simulates a critical section by acquiring the semaphore, sleeping for 1 second and then releasing the semaphore.

In the main function, 5 worker threads are created and started, each trying to enter the critical section. If the count of the semaphore is already 0, a worker will wait until another worker releases the semaphore (increasing its value).

Composable guards

Composable guards operate in a manner similar to locks, but are applied only to asynchronous functions. The guard (or guards) is automatically locked at the beginning of a specified task and automatically unlocked at the end. Because guards are never added to an existing task's execution context, the calling of guards is freely composable and can never deadlock.

To call an application with a single guard, simply declare the guard and call `run_guarded()` with a function `(task)`:

```
hpx::lcos::local::guard gu;
run_guarded(gu,task);
```

If a single method needs to run with multiple guards, use a guard set:

```
std::shared_ptr<hpx::lcos::local::guard> gu1(new hpx::lcos::local::guard());
std::shared_ptr<hpx::lcos::local::guard> gu2(new hpx::lcos::local::guard());
gs.add(*gu1);
gs.add(*gu2);
run_guarded(gs,task);
```

Guards use two atomic operations (which are not called repeatedly) to manage what they do, so overhead should be extremely low.

Execution control

The following objects are providing control of the execution in *HPX* applications:

1. *Futures*
2. *Channels*
3. *Task blocks*
4. *Task groups*
5. *Threads*

Futures

Futures are a mechanism to represent the result of a potentially asynchronous operation. A future is a type that represents a value that will become available at some point in the future, and it can be used to write asynchronous and parallel code. Futures can be returned from functions that perform time-consuming operations, allowing the calling code to continue executing while the function performs its work. The value of the future is set when the operation completes and can be accessed later. Futures are used in *HPX* to write asynchronous and parallel code. Below is an example demonstrating different features of futures:

```
#include <hpx/assert.hpp>
#include <hpx/future.hpp>
#include <hpx/hpx_main.hpp>
#include <hpx/tuple.hpp>

#include <iostream>
#include <utility>

int main()
{
    // Asynchronous execution with futures
    hpx::future<void> f1 = hpx::async(hpx::launch::async, []() {});
    hpx::shared_future<int> f2 =
        hpx::async(hpx::launch::async, []() { return 42; });
    hpx::future<int> f3 =
        f2.then([](hpx::shared_future<int>&& f) { return f.get() * 3; });

    hpx::promise<double> p;
    auto f4 = p.get_future();
    HPX_ASSERT(!f4.is_ready());
    p.set_value(123.45);
    HPX_ASSERT(f4.is_ready());

    hpx::packaged_task<int()> t([]() { return 43; });
    hpx::future<int> f5 = t.get_future();
    HPX_ASSERT(!f5.is_ready());
    t();
    HPX_ASSERT(f5.is_ready());

    // Fire-and-forget
    hpx::post([]() {
        std::cout << "This will be printed later\n" << std::flush;
    });

    // Synchronous execution
    hpx::sync([]() {
        std::cout << "This will be printed immediately\n" << std::flush;
    });

    // Combinators
    hpx::future<double> f6 = hpx::async([]() { return 3.14; });
    hpx::future<double> f7 = hpx::async([]() { return 42.0; });
    std::cout
        << hpx::when_all(f6, f7)
```

(continues on next page)

(continued from previous page)

```
              .then([](hpx::future<
                         hpx::tuple<hpx::future<double>, hpx::future<double>>>
                             f) {
                  hpx::tuple<hpx::future<double>, hpx::future<double>> t =
                      f.get();
                  double pi = hpx::get<0>(t).get();
                  double r = hpx::get<1>(t).get();
                  return pi * r * r;
              })
              .get()
          << std::endl;

    // Easier continuations with dataflow; it waits for all future or
    // shared_future arguments before executing the continuation, and also
    // accepts non-future arguments
    hpx::future<double> f8 = hpx::async([]() { return 3.14; });
    hpx::future<double> f9 = hpx::make_ready_future(42.0);
    hpx::shared_future<double> f10 = hpx::async([]() { return 123.45; });
    hpx::future<hpx::tuple<double, double>> f11 = hpx::dataflow(
        [](hpx::future<double> a, hpx::future<double> b,
            hpx::shared_future<double> c, double d) {
            return hpx::make_tuple<>(a.get() + b.get(), c.get() / d);
        },
        f8, f9, f10, -3.9);

    // split_future gives a tuple of futures from a future of tuple
    hpx::tuple<hpx::future<double>, hpx::future<double>> f12 =
        hpx::split_future(std::move(f11));
    std::cout << hpx::get<1>(f12).get() << std::endl;

    return 0;
}
```

The first section of the main function demonstrates how to use futures for asynchronous execution. The first two lines create two futures, one for void and another for an integer, using the `hpx::async()` function. These futures are executed *asynchronously* in separate threads using the `hpx::launch::async` launch policy. The third future is created by *chaining* the second future using the `then()` member function. This future multiplies the result of the second future by 3.

The next part of the code demonstrates how to use *promises* and *packaged* tasks, which are constructs used for communicating data between threads. The `promise` class is used to store a value that can be retrieved *later* using a future. The `packaged_task` class represents a task that can be executed *asynchronously*, and its result can be obtained using a future. The last three lines create a packaged task that returns an integer, obtain its future, execute the task, and check whether the future is ready or not.

The code then demonstrates how to use the `hpx::post()` and `hpx::sync()` functions for *fire-and-forget* and *synchronous* execution, respectively. The `hpx::post()` function executes a given function *asynchronously* and *returns immediately* without waiting for the result. The `hpx::sync()` function executes a given function *synchronously* and *waits* for the result before returning.

Next the code demonstrates the use of *combinators*, which are higher-order functions that combine two or more futures into a single future. The `hpx::when_all()` function is used to combine two futures, which return double values, into a tuple of futures. The `then()` member function is then used to compute the area of a circle using the values of the two futures. The `get()` member function is used to retrieve the result of the computation.

The last section demonstrates the use of `hpx::dataflow()`, which is a higher-order function that waits for all the future or shared_future arguments to be ready before executing the continuation. The `hpx::make_ready_future()` function is used to create a future with a given value. The `hpx::split_future()` function is used to split a future of a tuple into a tuple of futures. The last line retrieves the value of the second future in the tuple using `hpx::get()` and prints it to the console.

Extended facilities for futures

Concurrency is about both decomposing and composing the program from the parts that work well individually and together. It is in the composition of connected and multicore components where today's C++ libraries are still lacking.

The functionality of std::future[77] offers a partial solution. It allows for the separation of the initiation of an operation and the act of waiting for its result; however, the act of waiting is synchronous. In communication-intensive code this act of waiting can be unpredictable, inefficient and simply frustrating. The example below illustrates a possible synchronous wait using futures:

```
#include <future>
using namespace std;
int main()
{
    future<int> f = async([]() { return 123; });
    int result = f.get(); // might block
}
```

For this reason, *HPX* implements a set of extensions to std::future[78] (as proposed by N4313[79]). This proposal introduces the following key asynchronous operations to *hpx::future*, *hpx::shared_future* and *hpx::async*, which enhance and enrich these facilities.

[77] http://en.cppreference.com/w/cpp/thread/future
[78] http://en.cppreference.com/w/cpp/thread/future
[79] http://wg21.link/n4313

Table 2.11: Facilities extending `std::future`

Facility	Description
`hpx::future::then`	In asynchronous programming, it is very common for one asynchronous operation, on completion, to invoke a second operation and pass data to it. The current C++ standard does not allow one to register a continuation to a future. With `then`, instead of waiting for the result, a continuation is "attached" to the asynchronous operation, which is invoked when the result is ready. Continuations registered using then function will help to avoid blocking waits or wasting threads on polling, greatly improving the responsiveness and scalability of an application.
unwrapping constructor for *hpx::future*	In some scenarios, you might want to create a future that returns another future, resulting in nested futures. Although it is possible to write code to unwrap the outer future and retrieve the nested future and its result, such code is not easy to write because users must handle exceptions and it may cause a blocking call. Unwrapping can allow users to mitigate this problem by doing an asynchronous call to unwrap the outermost future.
`hpx::future::is_r`	There are often situations where a `get()` call on a future may not be a blocking call, or is only a blocking call under certain circumstances. This function gives the ability to test for early completion and allows us to avoid associating a continuation, which needs to be scheduled with some non-trivial overhead and near-certain loss of cache efficiency.
hpx::make_ready_futu	Some functions may know the value at the point of construction. In these cases the value is immediately available, but needs to be returned as a future. By using `hpx::make_ready_future` a future can be created that holds a pre-computed result in its shared state. In the current standard it is non-trivial to create a future directly from a value. First a promise must be created, then the promise is set, and lastly the future is retrieved from the promise. This can now be done with one operation.

The standard also omits the ability to compose multiple futures. This is a common pattern that is ubiquitous in other asynchronous frameworks and is absolutely necessary in order to make C++ a powerful asynchronous programming language. Not including these functions is synonymous to Boolean algebra without AND/OR.

In addition to the extensions proposed by N4313[80], *HPX* adds functions allowing users to compose several futures in a more flexible way.

Table 2.12: Facilities for composing `hpx::futures`

Facility	Description
hpx::when_any, `hpx::when_any_n`	Asynchronously wait for at least one of multiple future or shared_future objects to finish.
hpx::wait_any, *hpx::wait_any_n*	Synchronously wait for at least one of multiple future or shared_future objects to finish.
hpx::when_all, `hpx::when_all_n`	Asynchronously wait for all future and shared_future objects to finish.
hpx::wait_all, *hpx::wait_all_n*	Synchronously wait for all future and shared_future objects to finish.
hpx::when_some, `hpx::when_some_n`	Asynchronously wait for multiple future and shared_future objects to finish.
hpx::wait_some, *hpx::wait_some_n*	Synchronously wait for multiple future and shared_future objects to finish.
hpx::when_each	Asynchronously wait for multiple future and shared_future objects to finish and call a function for each of the future objects as soon as it becomes ready.
hpx::wait_each, *hpx::wait_each_n*	Synchronously wait for multiple future and shared_future objects to finish and call a function for each of the future objects as soon as it becomes ready.

80 http://wg21.link/n4313

Channels

Channels combine communication (the exchange of a value) with synchronization (guaranteeing that two calculations (tasks) are in a known state). A channel can transport any number of values of a given type from a sender to a receiver:

```
    hpx::lcos::local::channel<int> c;
    hpx::future<int> f = c.get();
    HPX_ASSERT(!f.is_ready());
    c.set(42);
    HPX_ASSERT(f.is_ready());
    std::cout << f.get() << std::endl;
```

Channels can be handed to another thread (or in case of channel components, to other localities), thus establishing a communication channel between two independent places in the program:

```
void do_something(hpx::lcos::local::receive_channel<int> c,
    hpx::lcos::local::send_channel<> done)
{
    // prints 43
    std::cout << c.get(hpx::launch::sync) << std::endl;
    // signal back
    done.set();
}

void send_receive_channel()
{
    hpx::lcos::local::channel<int> c;
    hpx::lcos::local::channel<> done;

    hpx::post(&do_something, c, done);

    // send some value
    c.set(43);
    // wait for thread to be done
    done.get().wait();
}
```

Note how `hpx::lcos::local::channel::get` without any arguments returns a future which is ready when a value has been set on the channel. The launch policy `hpx::launch::sync` can be used to make `hpx::lcos::local::channel::get` block until a value is set and return the value directly.

A channel component is created on one *locality* and can be sent to another *locality* using an action. This example also demonstrates how a channel can be used as a range of values:

```
// channel components need to be registered for each used type (not needed
// for hpx::lcos::local::channel)
HPX_REGISTER_CHANNEL(double)

void channel_sender(hpx::lcos::channel<double> c)
{
    for (double d : c)
        hpx::cout << d << std::endl;
}
HPX_PLAIN_ACTION(channel_sender)
```

(continues on next page)

(continued from previous page)

```
void channel()
{
    // create the channel on this locality
    hpx::lcos::channel<double> c(hpx::find_here());

    // pass the channel to a (possibly remote invoked) action
    hpx::post(channel_sender_action(), hpx::find_here(), c);

    // send some values to the receiver
    std::vector<double> v = {1.2, 3.4, 5.0};
    for (double d : v)
        c.set(d);

    // explicitly close the communication channel (implicit at destruction)
    c.close();
}
```

Task blocks

Task blocks in *HPX* provide a way to structure and organize the execution of tasks in a parallel program, making it easier to manage dependencies between tasks. A task block actually is a group of tasks that can be executed in parallel. Tasks in a task block can depend on other tasks in the same task block. The task block allows the runtime to optimize the execution of tasks, by scheduling them in an optimal order based on the dependencies between them.

The `define_task_block`, `run` and the `wait` functions implemented based on N4755[81] are based on the `task_block` concept that is a part of the common subset of the Microsoft Parallel Patterns Library (PPL)[82] and the Intel Threading Building Blocks (TBB)[83] libraries.

These implementations adopt a simpler syntax than exposed by those libraries— one that is influenced by language-based concepts, such as spawn and sync from Cilk++[84] and async and finish from X10[85]. They improve on existing practice in the following ways:

- The exception handling model is simplified and more consistent with normal C++ exceptions.
- Most violations of strict fork-join parallelism can be enforced at compile time (with compiler assistance, in some cases).
- The syntax allows scheduling approaches other than child stealing.

Consider an example of a parallel traversal of a tree, where a user-provided function compute is applied to each node of the tree, returning the sum of the results:

```
template <typename Func>
int traverse(node& n, Func && compute)
{
    int left = 0, right = 0;
    define_task_block(
        [&](task_block<>& tr) {
```

(continues on next page)

[81] http://wg21.link/n4755
[82] https://msdn.microsoft.com/en-us/library/dd492418.aspx
[83] https://www.threadingbuildingblocks.org/
[84] https://software.intel.com/en-us/articles/intel-cilk-plus/
[85] https://x10-lang.org/

(continued from previous page)

```
            if (n.left)
                tr.run([&] { left = traverse(*n.left, compute); });
            if (n.right)
                tr.run([&] { right = traverse(*n.right, compute); });
        });

    return compute(n) + left + right;
}
```

The example above demonstrates the use of two of the functions, *hpx::experimental::define_task_block* and the `hpx::experimental::task_block::run` member function of a *hpx::experimental::task_block*.

The `task_block` function delineates a region in a program code potentially containing invocations of threads spawned by the `run` member function of the `task_block` class. The `run` function spawns an *HPX* thread, a unit of work that is allowed to execute in parallel with respect to the caller. Any parallel tasks spawned by `run` within the task block are joined back to a single thread of execution at the end of the `define_task_block`. `run` takes a user-provided function object `f` and starts it asynchronously—i.e., it may return before the execution of `f` completes. The *HPX* scheduler may choose to run `f` immediately or delay running `f` until compute resources become available.

A `task_block` can be constructed only by `define_task_block` because it has no public constructors. Thus, `run` can be invoked directly or indirectly only from a user-provided function passed to `define_task_block`:

```
void g();

void f(task_block<>& tr)
{
    tr.run(g);          // OK, invoked from within task_block in h
}

void h()
{
    define_task_block(f);
}

int main()
{
    task_block<> tr;    // Error: no public constructor
    tr.run(g);          // No way to call run outside of a define_task_block
    return 0;
}
```

Extensions for task blocks

Using execution policies with task blocks

HPX implements some extensions for `task_block` beyond the actual standards proposal N4755[86]. The main addition is that a `task_block` can be invoked with an execution policy as its first argument, very similar to the parallel algorithms.

An execution policy is an object that expresses the requirements on the ordering of functions invoked as a consequence of the invocation of a task block. Enabling passing an execution policy to `define_task_block` gives the user control

[86] http://wg21.link/n4755

over the amount of parallelism employed by the created `task_block`. In the following example the use of an explicit `par` execution policy makes the user's intent explicit:

```
template <typename Func>
int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par,                // execution::parallel_policy
        [&](task_block<>& tb) {
            if (n->left)
                tb.run([&] { left = traverse(n->left, compute); });
            if (n->right)
                tb.run([&] { right = traverse(n->right, compute); });
        });

    return compute(n) + left + right;
}
```

This also causes the *hpx::experimental::task_block* object to be a template in our implementation. The template argument is the type of the execution policy used to create the task block. The template argument defaults to *hpx::execution::parallel_policy*.

HPX still supports calling *hpx::experimental::define_task_block* without an explicit execution policy. In this case the task block will run using the *hpx::execution::parallel_policy*.

HPX also adds the ability to access the execution policy that was used to create a given `task_block`.

Using executors to run tasks

Often, users want to be able to not only define an execution policy to use by default for all spawned tasks inside the task block, but also to customize the execution context for one of the tasks executed by `task_block::run`. Adding an optionally passed executor instance to that function enables this use case:

```
template <typename Func>
int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par,                // execution::parallel_policy
        [&](auto& tb) {
            if (n->left)
            {
                // use explicitly specified executor to run this task
                tb.run(my_executor(), [&] { left = traverse(n->left, compute); });
            }
            if (n->right)
            {
                // use the executor associated with the par execution policy
                tb.run([&] { right = traverse(n->right, compute); });
            }
        });
```

(continues on next page)

(continued from previous page)

```
    return compute(n) + left + right;
}
```

HPX still supports calling `hpx::experimental::task_block::run` without an explicit executor object. In this case the task will be run using the executor associated with the execution policy that was used to call *hpx::experimental::define_task_block*.

Task groups

A *task group* in *HPX* is a synchronization primitive that allows you to execute a group of tasks concurrently and wait for their completion before continuing. The tasks in an `hpx::experimental::task_group` can be added dynamically. This is the *HPX* implementation of *tbb::task_group* of the Intel Threading Building Blocks (TBB)[87] library.

The example below shows that to use a task group, you simply create an `hpx::task_group` object and add tasks to it using the `run()` method. Once all the tasks have been added, you can call the `wait()` method to synchronize the tasks and wait for them to complete.

```
#include <hpx/experimental/task_group.hpp>
#include <hpx/init.hpp>

#include <iostream>

void task1()
{
    std::cout << "Task 1 executed." << std::endl;
}

void task2()
{
    std::cout << "Task 2 executed." << std::endl;
}

int hpx_main()
{
    hpx::experimental::task_group tg;

    tg.run(task1);
    tg.run(task2);

    tg.wait();

    std::cout << "All tasks finished!" << std::endl;

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

[87] https://www.threadingbuildingblocks.org/

Note

task groups and *task blocks* are both ways to group and synchronize parallel tasks, but *task groups* are used to group multiple tasks together as a single unit, while *task blocks* are used to execute a loop in parallel, with each iteration of the loop executing in a separate task. If the difference is not clear yet, continue reading.

A *task group* is a construct that allows multiple parallel tasks to be grouped together as a single unit. The task group provides a way to synchronize all the tasks in the group before continuing with the rest of the program.

A *task block*, on the other hand, is a parallel loop construct that allows you to execute a loop in parallel, with each iteration of the loop executing in a separate task. The loop iterations are executed in a block, meaning that the loop body is executed as a single task.

Threads

A thread in *HPX* refers to a sequence of instructions that can be executed concurrently with other such sequences in multithreading environments, while sharing a same address space. These threads can communicate with each other through various means, such as futures or shared data structures.

The example below demonstrates how to launch multiple threads and synchronize them using a `hpx::latch` object. It also shows how to query the state of threads and wait for futures to complete.

```
#include <hpx/future.hpp>
#include <hpx/init.hpp>
#include <hpx/thread.hpp>

#include <functional>
#include <iostream>
#include <vector>

int const num_threads = 10;

///////////////////////////////////////////////////////////////////////////////
void wait_for_latch(hpx::latch& l)
{
    l.arrive_and_wait();
}

int hpx_main()
{
    // Spawn a couple of threads
    hpx::latch l(num_threads + 1);

    std::vector<hpx::future<void>> results;
    results.reserve(num_threads);

    for (int i = 0; i != num_threads; ++i)
        results.push_back(hpx::async(&wait_for_latch, std::ref(l)));

    // Allow spawned threads to reach latch
    hpx::this_thread::yield();

    // Enumerate all suspended threads
```

(continues on next page)

(continued from previous page)

```
    hpx::threads::enumerate_threads(
        [](hpx::threads::thread_id_type id) -> bool {
            std::cout << "thread " << hpx::thread::id(id) << " is "
                      << hpx::threads::get_thread_state_name(
                             hpx::threads::get_thread_state(id))
                      << std::endl;
            return true;    // always continue enumeration
        },
        hpx::threads::thread_schedule_state::suspended);

    // Wait for all threads to reach this point.
    l.arrive_and_wait();

    hpx::wait_all(results);

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

In more detail, the `wait_for_latch()` function is a simple helper function that waits for a `hpx::latch` object to be released. At this point we remind that `hpx::latch` is a synchronization primitive that allows multiple threads to wait for a common event to occur.

In the `hpx_main()` function, an `hpx::latch` object is created with a count of `num_threads + 1`, indicating that `num_threads` threads need to arrive at the latch before the latch is released. The loop that follows launches `num_threads` asynchronous operations, each of which calls the `wait_for_latch` function. The resulting futures are added to the vector.

After the threads have been launched, `hpx::this_thread::yield()` is called to give them a chance to reach the latch before the program proceeds. Then, the `hpx::threads::enumerate_threads` function prints the state of each suspended thread, while the next call of `l.arrive_and_wait()` waits for all the threads to reach the latch. Finally, `hpx::wait_all` is called to wait for all the futures to complete.

Hint

An advantage of using `hpx::thread` over other threading libraries is that it is optimized for high-performance parallelism, with support for lightweight threads and task scheduling to minimize thread overhead and maximize parallelism. Additionally, `hpx::thread` integrates seamlessly with other features of *HPX* such as futures, promises, and task groups, making it a powerful tool for parallel programming.

Checkout the examples of *Shared mutex*, *Condition variable*, *Semaphore* to see how *HPX* threads are used in combination with other features.

High level parallel facilities

In preparation for the upcoming C++ Standards, there are currently several proposals targeting different facilities supporting parallel programming. *HPX* implements (and extends) some of those proposals. This is well aligned with our strategy to align the APIs exposed from *HPX* with current and future C++ Standards.

At this point, *HPX* implements several of the C++ Standardization working papers, most notably N4409[88] (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4755[89] (Task Blocks), and N4406[90] (Parallel Algorithms Need Executors).

Using parallel algorithms

A parallel algorithm is a function template declared in the namespace `hpx::parallel`.

All parallel algorithms are very similar in semantics to their sequential counterparts (as defined in the `namespace std`) with an additional formal template parameter named `ExecutionPolicy`. The execution policy is generally passed as the first argument to any of the parallel algorithms and describes the manner in which the execution of these algorithms may be parallelized and the manner in which they apply user-provided function objects.

The applications of function objects in parallel algorithms invoked with an execution policy object of type *hpx::execution::sequenced_policy* or *hpx::execution::sequenced_task_policy* execute in sequential order. For *hpx::execution::sequenced_policy* the execution happens in the calling thread.

The applications of function objects in parallel algorithms invoked with an execution policy object of type *hpx::execution::parallel_policy* or *hpx::execution::parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and are indeterminately sequenced within each thread.

Important

It is the caller's responsibility to ensure correctness, such as making sure that the invocation does not introduce data races or deadlocks.

The example below demonstrates how to perform a sequential and parallel *hpx::for_each* loop on a vector of integers.

```
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>
#include <hpx/init.hpp>

#include <iostream>
#include <vector>

int hpx_main()
{
    std::vector<int> v{1, 2, 3, 4, 5};

    auto print = [](int const& n) { std::cout << n << ' '; };

    std::cout << "Print sequential: ";
    hpx::for_each(v.begin(), v.end(), print);
    std::cout << '\n';
```

(continues on next page)

[88] http://wg21.link/n4409
[89] http://wg21.link/n4755
[90] http://wg21.link/n4406

(continued from previous page)

```
    std::cout << "Print parallel: ";
    hpx::for_each(hpx::execution::par, v.begin(), v.end(), print);
    std::cout << '\n';

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

The above code uses `hpx::for_each` to print the elements of the vector `v{1, 2, 3, 4, 5}`. At first, `hpx::for_each()` is called without an execution policy, which means that it applies the lambda function `print` to each element in the vector sequentially. Hence, the elements are printed in order.

Next, `hpx::for_each()` is called with the `hpx::execution::par` execution policy, which applies the lambda function `print` to each element in the vector in parallel. Therefore, the output order of the elements in the vector is not deterministic and may vary from run to run.

Parallel exceptions

During the execution of a standard parallel algorithm, if temporary memory resources are required by any of the algorithms and no memory is available, the algorithm throws a `std::bad_alloc` exception.

During the execution of any of the parallel algorithms, if the application of a function object terminates with an uncaught exception, the behavior of the program is determined by the type of execution policy used to invoke the algorithm:

- If the execution policy object is of type *hpx::execution::parallel_unsequenced_policy*, `hpx::terminate` shall be called.
- If the execution policy object is of type *hpx::execution::sequenced_policy*, *hpx::execution::sequenced_task_policy*, *hpx::execution::parallel_policy*, or *hpx::execution::parallel_task_policy*, the execution of the algorithm terminates with an *`hpx::exception_list`* exception. All uncaught exceptions thrown during the application of user-provided function objects shall be contained in the *`hpx::exception_list`*.

For example, the number of invocations of the user-provided function object in for_each is unspecified. When *hpx::for_each* is executed sequentially, only one exception will be contained in the *`hpx::exception_list`* object.

These guarantees imply that, unless the algorithm has failed to allocate memory and terminated with `std::bad_alloc`, all exceptions thrown during the execution of the algorithm are communicated to the caller. It is unspecified whether an algorithm implementation will "forge ahead" after encountering and capturing a user exception.

The algorithm may terminate with the `std::bad_alloc` exception even if one or more user-provided function objects have terminated with an exception. For example, this can happen when an algorithm fails to allocate memory while creating or adding elements to the *`hpx::exception_list`* object.

Parallel algorithms

HPX provides implementations of the following parallel algorithms:

Table 2.13: Non-modifying parallel algorithms of header hpx/algorithm.hpp

Name	Description	C++ standard
hpx::adjacent_find	Computes the differences between adjacent elements in a range.	adjacent_find[91]
hpx::all_of	Checks if a predicate is `true` for all of the elements in a range.	all_any_none_of[92]
hpx::any_of	Checks if a predicate is `true` for any of the elements in a range.	all_any_none_of[93]
hpx::count	Returns the number of elements equal to a given value.	count[94]
hpx::count_if	Returns the number of elements satisfying a specific criteria.	count_if[95]
hpx::equal	Determines if two sets of elements are the same.	equal[96]
hpx::find	Finds the first element equal to a given value.	find[97]
hpx::find_end	Finds the last sequence of elements in a certain range.	find_end[98]
hpx::find_first_of	Searches for any one of a set of elements.	find_first_of[99]
hpx::find_if	Finds the first element satisfying a specific criteria.	find_if[100]
hpx::find_if_not	Finds the first element not satisfying a specific criteria.	find_if_not[101]
hpx::for_each	Applies a function to a range of elements.	for_each[102]
hpx::for_each_n	Applies a function to a number of elements.	for_each_n[103]
hpx::lexicographical_compa	Checks if a range of values is lexicographically less than another range of values.	lexicographical_compare[104]
hpx::mismatch	Finds the first position where two ranges differ.	mismatch[105]
hpx::none_of	Checks if a predicate is `true` for none of the elements in a range.	all_any_none_of[106]
hpx::search	Searches for a range of elements.	search[107]
hpx::search_n	Searches for a number consecutive copies of an element in a range.	search_n[108]

Table 2.14: Modifying parallel algorithms of header hpx/algorithm.hpp

Name	Description	C++ standard
hpx::copy	Copies a range of elements to a new location.	exclusive_scan[109]
hpx::copy_n	Copies a number of elements to a new location.	copy_n[110]
hpx::copy_if	Copies the elements from a range to a new location for which the given predicate is `true`	copy[111]
hpx::move	Moves a range of elements to a new location.	move[112]
hpx::fill	Assigns a range of elements a certain value.	fill[113]
hpx::fill_n	Assigns a value to a number of elements.	fill_n[114]
hpx::generate	Saves the result of a function in a range.	generate[115]
hpx::generate_n	Saves the result of N applications of a function.	generate_n[116]
`hpx::experimental::re`	Performs an inclusive scan on consecutive elements with matching keys, with a reduction to output only the final sum for each key. The key sequence `{1,1,1,2,3,3,3,3,1}` and value sequence `{2,3,4,5,6,7,8,9,10}` would be reduced to `keys={1,2,3,1}`, `values={9,5,30,10}`.	
hpx::remove	Removes the elements from a range that are equal to the given value.	remove[117]
hpx::remove_if	Removes the elements from a range that are equal to the given predicate is `false`	remove[118]
hpx::remove_copy	Copies the elements from a range to a new location that are not equal to the given value.	remove_copy[119]
hpx::remove_copy_if	Copies the elements from a range to a new location for which the given predicate is `false`	remove_copy[120]
hpx::replace	Replaces all values satisfying specific criteria with another value.	replace[121]
hpx::replace_if	Replaces all values satisfying specific criteria with another value.	replace[122]
hpx::replace_copy	Copies a range, replacing elements satisfying specific criteria with another value.	replace_copy[123]
hpx::replace_copy_if	Copies a range, replacing elements satisfying specific criteria with another value.	replace_copy[124]
hpx::reverse	Reverses the order elements in a range.	reverse[125]
hpx::reverse_copy	Creates a copy of a range that is reversed.	reverse_copy[126]
hpx::rotate	Rotates the order of elements in a range.	rotate[127]
hpx::rotate_copy	Copies and rotates a range of elements.	rotate_copy[128]
hpx::shift_left	Shifts the elements in the range left by n positions.	shift_left[129]
hpx::shift_right	Shifts the elements in the range right by n positions.	shift_right[130]
hpx::swap_ranges	Swaps two ranges of elements.	swap_ranges[131]
hpx::transform	Applies a function to a range of elements.	transform[132]
hpx::unique	Eliminates all but the first element from every consecutive group of equivalent elements from a range.	unique[133]
hpx::unique_copy	Copies the elements from one range to another in such a way that there are no consecutive equal elements.	unique_copy[134]

Table 2.15: Set operations on sorted sequences of header hpx/algorithm.hpp

Name	Description	C++ standard
hpx::merge	Merges two sorted ranges.	merge[135]
hpx::inplace_merge	Merges two ordered ranges in-place.	inplace_merge[136]
hpx::includes	Returns true if one set is a subset of another.	includes[137]
hpx::set_difference	Computes the difference between two sets.	set_difference[138]
hpx::set_intersection	Computes the intersection of two sets.	set_intersection[139]
hpx::set_symmetric_differer	Computes the symmetric difference between two sets.	set_symmetric_difference[140]
hpx::set_union	Computes the union of two sets.	set_union[141]

Table 2.16: Heap operations of header hpx/algorithm.hpp

Name	Description	C++ standard
hpx::is_heap	Returns `true` if the range is max heap.	is_heap[142]
hpx::is_heap_until	Returns the first element that breaks a max heap.	is_heap_until[143]
hpx::make_heap	Constructs a max heap in the range [first, last).	make_heap[144]

Table 2.17: Minimum/maximum operations of header hpx/algorithm.hpp

Name	Description	C++ standard
hpx::max_element	Returns the largest element in a range.	max_element[145]
hpx::min_element	Returns the smallest element in a range.	min_element[146]
hpx::minmax_element	Returns the smallest and the largest element in a range.	minmax_element[147]

Table 2.18: Partitioning Operations of header hpx/algorithm.hpp

Name	Description	C++ standard
hpx::nth_element	Partially sorts the given range making sure that it is partitioned by the given element	nth_element[148]
hpx::is_partitioned	Returns `true` if each true element for a predicate precedes the false elements in a range.	is_partitioned[149]
hpx::partition	Divides elements into two groups without preserving their relative order.	partition[150]
hpx::partition_copy	Copies a range dividing the elements into two groups.	partition_copy[151]
hpx::stable_partition	Divides elements into two groups while preserving their relative order.	stable_partition[152]

Table 2.19: Sorting Operations of header hpx/algorithm.hpp

Name	Description	C++ standard
hpx::is_sorted	Returns `true` if each element in a range is sorted.	is_sorted[153]
hpx::is_sorted_until	Returns the first unsorted element.	is_sorted_until[154]
hpx::sort	Sorts the elements in a range.	sort[155]
hpx::stable_sort	Sorts the elements in a range, maintain sequence of equal elements.	stable_sort[156]
hpx::partial_sort	Sorts the first elements in a range.	partial_sort[157]
hpx::partial_sort_copy	Sorts the first elements in a range, storing the result in another range.	partial_sort_copy[158]
*hpx::experimental::sort_by_*	Sorts one range of data using keys supplied in another range.	

Table 2.20: Numeric Parallel Algorithms of header hpx/numeric.hpp

Name	Description	C++ standard
hpx::adjacent_difference	Calculates the difference between each element in an input range and the preceding element.	adjacent_difference[159]
hpx::exclusive_scan	Does an exclusive parallel scan over a range of elements.	exclusive_scan[160]
hpx::inclusive_scan	Does an inclusive parallel scan over a range of elements.	inclusive_scan[161]
hpx::reduce	Sums up a range of elements.	reduce[162]
hpx::transform_exclusive_s	Does an exclusive parallel scan over a range of elements after applying a function.	transform_exclusive_scan[163]
hpx::transform_inclusive_s	Does an inclusive parallel scan over a range of elements after applying a function.	transform_inclusive_scan[164]
hpx::transform_reduce	Sums up a range of elements after applying a function. Also, accumulates the inner products of two input ranges.	transform_reduce[165]

Table 2.21: Dynamic Memory Management of header hpx/memory.hpp

Name	Description	C++ standard
hpx::destroy	Destroys a range of objects.	destroy[166]
hpx::destroy_n	Destroys a range of objects.	destroy_n[167]
hpx::uninitialized_copy	Copies a range of objects to an uninitialized area of memory.	uninitial-ized_copy[168]
hpx::uninitialized_copy_n	Copies a number of objects to an uninitialized area of memory.	uninitial-ized_copy_n[169]
hpx::uninitialized_default_c	Copies a range of objects to an uninitialized area of memory.	uninitial-ized_default_construct[170]
hpx::uninitialized_default_c	Copies a number of objects to an uninitialized area of memory.	uninitial-ized_default_construct_n[171]
hpx::uninitialized_fill	Copies an object to an uninitialized area of memory.	uninitialized_fill[172]
hpx::uninitialized_fill_n	Copies an object to an uninitialized area of memory.	uninitial-ized_fill_n[173]
hpx::uninitialized_move	Moves a range of objects to an uninitialized area of memory.	uninitial-ized_move[174]
hpx::uninitialized_move_n	Moves a number of objects to an uninitialized area of memory.	uninitial-ized_move_n[175]
hpx::uninitialized_value_co	Constructs objects in an uninitialized area of memory.	uninitial-ized_value_construct[176]
hpx::uninitialized_value_co	Constructs objects in an uninitialized area of memory.	uninitial-ized_value_construct_n[177]

Table 2.22: Index-based for-loops of header hpx/algorithm.hpp

Name	Description
hpx::experimental::for_loop	Implements loop functionality over a range specified by integral or iterator bounds.
hpx::experimental::for_loop_strided	Implements loop functionality over a range specified by integral or iterator bounds.
hpx::experimental::for_loop_n	Implements loop functionality over a range specified by integral or iterator bounds.
hpx::experimental::for_loop_n_stride	Implements loop functionality over a range specified by integral or iterator bounds.

Executor parameters and executor parameter traits

HPX introduces the notion of execution parameters and execution parameter traits. At this point, the only parameter that can be customized is the size of the chunks of work executed on a single *HPX* thread (such as the number of loop iterations combined to run as a single task).

An executor parameter object is responsible for exposing the calculation of the size of the chunks scheduled. It abstracts the (potentially platform-specific) algorithms of determining those chunk sizes.

The way executor parameters are implemented is aligned with the way executors are implemented. All functionalities of concrete executor parameter types are exposed and accessible through a corresponding customization point, e.g. `get_chunk_size()`.

With `executor_parameter_traits`, clients access all types of executor parameters uniformly, e.g.:

```
std::size_t chunk_size =
    hpx::execution::experimental::get_chunk_size(my_parameter, my_executor,
        num_cores, num_tasks);
```

This call synchronously retrieves the size of a single chunk of loop iterations (or similar) to combine for execution on a single *HPX* thread if the overall number of cores `num_cores` and tasks to schedule is given by `num_tasks`. The lambda function exposes a means of test-probing the execution of a single iteration for performance measurement purposes. The execution parameter type might dynamically determine the execution time of one or more tasks in order to calculate the chunk size; see *hpx::execution::experimental::auto_chunk_size* for an example of this executor parameter type.

Other functions in the interface exist to discover whether an executor parameter type should be invoked once (i.e., it returns a static chunk size; see *hpx::execution::experimental::static_chunk_size*) or whether it should be invoked for each scheduled chunk of work (i.e., it returns a variable chunk size; for an example, see *hpx::execution::experimental::guided_chunk_size*).

Although this interface appears to require executor parameter type authors to implement all different basic operations, none are required. In practice, all operations have sensible defaults. However, some executor parameter types will naturally specialize all operations for maximum efficiency.

HPX implements the following executor parameter types:

- *hpx::execution::experimental::auto_chunk_size*: Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameter type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.
- *hpx::execution::experimental::static_chunk_size*: Loop iterations are divided into pieces of a given size and then assigned to threads. If the size is not specified, the iterations are, if possible, evenly divided contiguously among the threads. This executor parameters type is equivalent to OpenMP's STATIC scheduling directive.
- *hpx::execution::experimental::dynamic_chunk_size*: Loop iterations are divided into pieces of a given size and then dynamically scheduled among the cores; when a core finishes one chunk, it is dynamically assigned another. If the size is not specified, the default chunk size is 1. This executor parameter type is equivalent to OpenMP's DYNAMIC scheduling directive.
- *hpx::execution::experimental::guided_chunk_size*: Iterations are dynamically assigned to cores in blocks as cores request them until no blocks remain to be assigned. This is similar to `dynamic_chunk_size` except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to `number_of_iterations / number_of_cores`. Subsequent blocks are proportional to `number_of_iterations_remaining / number_of_cores`. The optional chunk size parameter defines the minimum block size. The default minimal chunk size is 1. This executor parameter type is equivalent to OpenMP's GUIDED scheduling directive.

2.4.12 Writing distributed applications

This section focuses on the features of *HPX* needed to write distributed applications, namely the *Active Global Address Space* (*AGAS*), remotely executable functions (i.e., *actions*), and distributed objects (i.e., *components*).

Global names

HPX implements an *Active Global Address Space* (*AGAS*) which exposes a single uniform address space spanning all localities an application runs on. AGAS is a fundamental component of the ParalleX execution model. Conceptually, there is no rigid demarcation of local or global memory in AGAS; all available memory is a part of the same address space. AGAS enables named objects to be moved (migrated) across localities without having to change the object's name; i.e., no references to migrated objects have to be ever updated. This feature has significance for dynamic load balancing and in applications where the workflow is highly dynamic, allowing work to be migrated from heavily loaded nodes to less loaded nodes. In addition, immutability of names ensures that AGAS does not have to keep extra indirections ("bread crumbs") when objects move, hence, minimizing complexity of code management for system developers as well as minimizing overheads in maintaining and managing aliases.

The AGAS implementation in *HPX* does not automatically expose every local address to the global address space. It is the responsibility of the programmer to explicitly define which of the objects have to be globally visible and which of the objects are purely local.

In *HPX* global addresses (global names) are represented using the `hpx::id_type` data type. This data type is conceptually very similar to `void*` pointers as it does not expose any type information of the object it is referring to.

The only predefined global addresses are assigned to all localities. The following *HPX* API functions allow one to retrieve the global addresses of localities:

- `hpx::find_here`: retrieves the global address of the *locality* this function is called on.
- `hpx::find_all_localities`: retrieves the global addresses of all localities available to this application (including the *locality* the function is being called on).
- `hpx::find_remote_localities`: retrieves the global addresses of all remote localities available to this application (not including the *locality* the function is being called on).
- `hpx::get_num_localities`: retrieves the number of localities available to this application.
- `hpx::find_locality`: retrieves the global address of any *locality* supporting the given component type.
- `hpx::get_colocation_id`: retrieves the global address of the *locality* currently hosting the object with the given global address.

Additionally, the global addresses of localities can be used to create new instances of components using the following *HPX* API function:

- `hpx::components::new_`: Creates a new instance of the given `Component` type on the specified *locality*.

Note

HPX does not expose any functionality to delete component instances. All global addresses (as represented using `hpx::id_type`) are automatically garbage collected. When the last (global) reference to a particular component instance goes out of scope, the corresponding component instance is automatically deleted.

Posting actions

Action type definition

Actions are special types used to describe possibly remote operations. For every global function and every member function which has to be invoked distantly, a special type must be defined. For any global function the special macro *HPX_PLAIN_ACTION* can be used to define the action type. Here is an example demonstrating this:

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action);
```

Important

The macro *HPX_PLAIN_ACTION* has to be placed in global namespace, even if the wrapped function is located in some other namespace. The newly defined action type is placed in the global namespace as well.

If the action type should be defined somewhere not in global namespace, the action type definition has to be split into two macro invocations (*HPX_DEFINE_PLAIN_ACTION* and *HPX_REGISTER_ACTION*) as shown in the next example:

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // On conforming compilers the following macro expands to:
    //
    //    typedef hpx::actions::make_action<
    //        decltype(&some_global_function), &some_global_function
    //    >::type some_global_action;
    //
    // This will define the action type 'some_global_action' which represents
    // the function 'some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}

// The following macro expands to a series of definitions of global objects
// which are needed for proper serialization and initialization support
// enabling the remote invocation of the function``some_global_function``
HPX_REGISTER_ACTION(app::some_global_action, app_some_global_action);
```

The shown code defines an action type `some_global_action` inside the namespace `app`.

Important

If the action type definition is split between two macros as shown above, the name of the action type to create has to be the same for both macro invocations (here `some_global_action`).

Important

The second argument passed to *HPX_REGISTER_ACTION* (`app_some_global_action`) has to comprise a globally unique C++ identifier representing the action. This is used for serialization purposes.

For member functions of objects which have been registered with AGAS (e.g., 'components'), a different registration macro *HPX_DEFINE_COMPONENT_ACTION* has to be utilized. Any component needs to be declared in a header file and have some special support macros defined in a source file. Here is an example demonstrating this. The first snippet has to go into the header file:

```
namespace app
{
    struct some_component
      : hpx::components::component_base<some_component>
    {
        int some_member_function(std::string s)
        {
            return std::stoi(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function,
            some_member_action);
    };
}

// Note: The second argument to the macro below has to be systemwide-unique
//       C++ identifiers
HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_component_
↪some_action);
```

The next snippet belongs in a source file (e.g., the main application source file) in the simplest case:

```
typedef hpx::components::component<app::some_component> component_type;
typedef app::some_component some_component;

HPX_REGISTER_COMPONENT(component_type, some_component);

// The parameters for this macro have to be the same as used in the corresponding
// HPX_REGISTER_ACTION_DECLARATION() macro invocation above
typedef some_component::some_member_action some_component_some_action;
HPX_REGISTER_ACTION(some_component_some_action);
```

While these macro invocations are a bit more complex than those for simple global functions, they should still be manageable.

The most important macro invocation is the *HPX_DEFINE_COMPONENT_ACTION* in the header file as this defines the action type we need to invoke the member function. For a complete example of a simple component action see `component_in_executable.cpp`.

Reflection-based component actions (experimental)

Note

This feature requires a compiler with C++26 reflection support (`HPX_HAVE_CXX26_REFLECTION`) and is currently experimental.

When reflection support is available, component actions can be defined with a single macro instead of the three-step process described above:

```
namespace app
{
    struct some_component
      : hpx::components::component_base<some_component>
    {
        int some_member_function(std::string s)
        {
            return std::stoi(s);
        }
        // This single line replaces HPX_DEFINE_COMPONENT_ACTION,
        // HPX_REGISTER_ACTION_DECLARATION, and HPX_REGISTER_ACTION.
        HPX_COMPONENT_ACTION(some_component, some_member_function,
            some_member_action);
    };
}
```

The resulting `some_member_action` type can be used exactly like an action type created with *HPX_DEFINE_COMPONENT_ACTION*, with *hpx::post*, *hpx::async*, and *hpx::sync*, or by invoking it directly. No separate registration step is required in the source file.

Action invocation

The process of invoking a global function (or a member function of an object) with the help of the associated action is called ‘posting the action’. Actions can have arguments, which will be supplied while the action is applied. At the minimum, one parameter is required to `post` any action - the id of the *locality* the associated function should be invoked on (for global functions), or the id of the component instance (for member functions). Generally, *HPX* provides several ways to `post` an action, all of which are described in the following sections.

Generally, *HPX* actions are very similar to ‘normal’ C++ functions except that actions can be invoked remotely. Fig. **??** below shows an overview of the main API exposed by HPX. This shows the function invocation syntax as defined by the C++ language (dark gray), the additional invocation syntax as provided through C++ Standard Library features (medium gray), and the extensions added by *HPX* (light gray) where:

- `f` function to invoke,
- `p..`: (optional) arguments,
- R: return type of `f`,

- `action`: action type defined by, *HPX_DEFINE_PLAIN_ACTION* or *HPX_DEFINE_COMPONENT_ACTION* encapsulating `f`,
- `a`: an instance of the type `action`,
- `id`: the global address the action is applied to.

R f(p...)	Synchronous (return R)	Asynchronous (return future<R>)	Fire & Forget (return void)
Functions (direct)	f(p…) C++	async(f, p…)	post(f, p…)
Functions (lazy)	bind(f, p…)(…)	async(bind(f, p…), …) C++ Library	post(bind(f, p…), …)
Actions (direct)	HPX_ACTION(f, a) a(id, p…)	HPX_ACTION(f, a) async(a, id, p…)	HPX_ACTION(f, a) post(a, id, p…)
Actions (lazy)	HPX_ACTION(f, a) bind(a, id, p…)(…)	HPX_ACTION(f, a) async(bind(a, id, p…), …)	HPX_ACTION(f, a) post(bind(a, id, p…), …) HPX

Fig. 2.8: Overview of the main API exposed by *HPX*.

This figure shows that *HPX* allows the user to `post` actions with a syntax similar to the C++ standard. In fact, all action types have an overloaded function operator allowing to synchronously `post` the action. Further, *HPX* implements `hpx::async` which semantically works similar to the way `std::async` works for plain C++ function.

> **Note**
>
> The similarity of posting an action to conventional function invocations extends even further. *HPX* implements `hpx::bind` and `hpx::function` two facilities which are semantically equivalent to the `std::bind` and `std::function` types as defined by the C++11 Standard. While `hpx::async` extends beyond the conventional semantics by supporting actions and conventional C++ functions, the *HPX* facilities `hpx::bind` and `hpx::function` extend beyond the conventional standard facilities too. The *HPX* facilities not only support conventional functions, but can be used for actions as well.

Additionally, *HPX* exposes `hpx::post` and `hpx::async_continue` both of which refine and extend the standard C++ facilities.

The different ways to invoke a function in *HPX* will be explained in more detail in the following sections.

Posting an action asynchronously without any synchronization

This method ('fire and forget') will make sure the function associated with the action is scheduled to run on the target *locality*. Posting the action does not wait for the function to start running, instead it is a fully asynchronous operation. The following example shows how to `post` the action as defined *in the previous section* on the local *locality* (the *locality* this code runs on):

```
some_global_action act;     // define an instance of some_global_action
hpx::post(act, hpx::find_here(), 2.0);
```

(the function `hpx::find_here()` returns the id of the local *locality*, i.e. the *locality* this code executes on).

Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```
some_component_action act;     // define an instance of some_component_action
hpx::post(act, id, "42");
```

In this case any value returned from this action (e.g. in this case the integer `42` is ignored. Please look at *Action type definition* for the code defining the component action `some_component_action` used.

Posting an action asynchronously with synchronization

This method will make sure the action is scheduled to run on the target *locality*. Posting the action itself does not wait for the function to start running or to complete, instead this is a fully asynchronous operation similar to using `hpx::post` as described above. The difference is that this method will return an instance of a `hpx::future<>` encapsulating the result of the (possibly remote) execution. The future can be used to synchronize with the asynchronous operation. The following example shows how to `post` the action from above on the local *locality*:

```
some_global_action act;     // define an instance of some_global_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), 2.0);
//
// ... other code can be executed here
//
f.get();    // this will possibly wait for the asynchronous operation to 'return'
```

(as before, the function `hpx::find_here()` returns the id of the local *locality* (the *locality* this code is executed on).

Note

The use of a `hpx::future<void>` allows the current thread to synchronize with any remote operation not returning any value.

Note

Any `std::future<>` returned from `std::async()` is required to block in its destructor if the value has not been set for this future yet. This is not true for `hpx::future<>` which will never block in its destructor, even if the value has not been returned to the future yet. We believe that consistency in the behavior of futures is more important than standards conformance in this case.

Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```
some_component_action act;     // define an instance of some_component_action
hpx::future<int> f = hpx::async(act, id, "42");
//
// ... other code can be executed here
//
cout << f.get();    // this will possibly wait for the asynchronous operation to 'return'
↪42
```

Note

The invocation of `f.get()` will return the result immediately (without suspending the calling thread) if the result from the asynchronous operation has already been returned. Otherwise, the invocation of `f.get()` will suspend the execution of the calling thread until the asynchronous operation returns its result.

Posting an action synchronously

This method will schedule the function wrapped in the specified action on the target *locality*. While the invocation appears to be synchronous (as we will see), the calling thread will be suspended while waiting for the function to return. Invoking a plain action (e.g. a global function) synchronously is straightforward:

```
some_global_action act;     // define an instance of some_global_action
act(hpx::find_here(), 2.0);
```

While this call looks just like a normal synchronous function invocation, the function wrapped by the action will be scheduled to run on a new thread and the calling thread will be suspended. After the new thread has executed the wrapped global function, the waiting thread will resume and return from the synchronous call.

Equivalently, any action wrapping a component member function can be invoked synchronously as follows:

```
some_component_action act;     // define an instance of some_component_action
int result = act(id, "42");
```

The action invocation will either schedule a new thread locally to execute the wrapped member function (as before, `id` is the global address of the component instance the member function should be invoked on), or it will send a parcel to the remote *locality* of the component causing a new thread to be scheduled there. The calling thread will be suspended until the function returns its result. This result will be returned from the synchronous action invocation.

It is very important to understand that this 'synchronous' invocation syntax in fact conceals an asynchronous function call. This is beneficial as the calling thread is suspended while waiting for the outcome of a potentially remote operation. The *HPX* thread scheduler will schedule other work in the meantime, allowing the application to make further progress while the remote result is computed. This helps overlapping computation with communication and hiding communication latencies.

Note

The syntax of posting an action is always the same, regardless whether the target *locality* is remote to the invocation *locality* or not. This is a very important feature of *HPX* as it frees the user from the task of keeping track what actions have to be applied locally and which actions are remote. If the target for posting an action is local, a new thread is automatically created and scheduled. Once this thread is scheduled and run, it will execute the function encapsulated by that action. If the target is remote, *HPX* will send a parcel to the remote *locality* which encapsulates the action and its parameters. Once the parcel is received on the remote *locality* *HPX* will create and schedule a new thread there. Once this thread runs on the remote *locality*, it will execute the function encapsulated by the action.

Posting an action with a continuation but without any synchronization

This method is very similar to the method described in section *Posting an action asynchronously without any synchronization*. The difference is that it allows the user to chain a sequence of asynchronous operations, while handing the (intermediate) results from one step to the next step in the chain. Where `hpx::post` invokes a single function using 'fire and forget' semantics, `hpx::post_continue` asynchronously triggers a chain of functions without the need for the execution flow 'to come back' to the invocation site. Each of the asynchronous functions can be executed on a different *locality*.

Posting an action with a continuation and with synchronization

This method is very similar to the method described in section *Posting an action asynchronously with synchronization*. In addition to what `hpx::async` can do, the functions `hpx::async_continue` takes an additional function argument. This function will be called as the continuation of the executed action. It is expected to perform additional operations and to make sure that a result is returned to the original invocation site. This method chains operations asynchronously by providing a continuation operation which is automatically executed once the first action has finished executing.

As an example we chain two actions, where the result of the first action is forwarded to the second action and the result of the second action is sent back to the original invocation site:

```
// first action
std::int32_t action1(std::int32_t i)
{
    return i+1;
}
HPX_PLAIN_ACTION(action1);    // defines action1_type

// second action
std::int32_t action2(std::int32_t i)
{
    return i*2;
}
HPX_PLAIN_ACTION(action2);    // defines action2_type

// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;     // define an instance of 'action1_type'
action2_type act2;     // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2),
        hpx::find_here(), 42);
hpx::cout << f.get() << "\n";   // will print: 86 ((42 + 1) * 2)
```

By default, the continuation is executed on the same *locality* as `hpx::async_continue` is invoked from. If you want to specify the *locality* where the continuation should be executed, the code above has to be written as:

```
// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;     // define an instance of 'action1_type'
action2_type act2;     // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2, hpx::find_here()),
        hpx::find_here(), 42);
hpx::cout << f.get() << "\n";   // will print: 86 ((42 + 1) * 2)
```

Similarly, it is possible to chain more than 2 operations:

```
action1_type act1;     // define an instance of 'action1_type'
action2_type act2;     // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1,
        hpx::make_continuation(act2, hpx::make_continuation(act1)),
        hpx::find_here(), 42);
hpx::cout << f.get() << "\n";   // will print: 87 ((42 + 1) * 2 + 1)
```

The function `hpx::make_continuation` creates a special function object which exposes the following prototype:

```
struct continuation
{
    template <typename Result>
    void operator()(hpx::id_type id, Result&& result) const
    {
        ...
    }
};
```

where the parameters passed to the overloaded function operator `operator()()` are:

- the `id` is the global id where the final result of the asynchronous chain of operations should be sent to (in most cases this is the id of the `hpx::future` returned from the initial call to `hpx::async_continue`. Any custom continuation function should make sure this `id` is forwarded to the last operation in the chain.
- the `result` is the result value of the current operation in the asynchronous execution chain. This value needs to be forwarded to the next operation.

Note

All of those operations are implemented by the predefined continuation function object which is returned from `hpx::make_continuation`. Any (custom) function object used as a continuation should conform to the same interface.

Action error handling

Like in any other asynchronous invocation scheme it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In *HPX* all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation *locality*, where it is rethrown during synchronization with the calling thread.

Important

Exceptions thrown during asynchronous execution can be transferred back to the invoking thread only for the synchronous and the asynchronous case with synchronization. Like with any other unhandled exception, any exception thrown during the execution of an asynchronous action *without* synchronization will result in calling `hpx::terminate` causing the running application to exit immediately.

Note

Even if error handling internally relies on exceptions, most of the API functions exposed by *HPX* can be used without throwing an exception. Please see *Working with exceptions* for more information.

As an example, we will assume that the following remote function will be executed:

```
namespace app
{
    void some_function_with_error(int arg)
    {
        if (arg < 0) {
            HPX_THROW_EXCEPTION(hpx::error::bad_parameter,
                "some_function_with_error",
                "some really bad error happened");
        }
        // do something else...
    }
}

// This will define the action type 'some_error_action' which represents
// the function 'app::some_function_with_error'.
HPX_PLAIN_ACTION(app::some_function_with_error, some_error_action);
```

The use of *HPX_THROW_EXCEPTION* to report the error encapsulates the creation of a *hpx::exception* which is initialized with the error code `hpx::error::bad_parameter`. Additionally it carries the passed strings, the information about the file name, line number, and call stack of the point the exception was thrown from.

We invoke this action using the synchronous syntax as described before:

```
// note: wrapped function will throw hpx::exception
some_error_action act;            // define an instance of some_error_action
try {
    act(hpx::find_here(), -3);    // exception will be rethrown from here
}
catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
```

(continues on next page)

(continued from previous page)

```
    cout << e.what();
}
```

If this action is invoked asynchronously with synchronization, the exception is propagated to the waiting thread as well and is re-thrown from the future's function `get()`:

```
// note: wrapped function will throw hpx::exception
some_error_action act;            // define an instance of some_error_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), -3);
try {
    f.get();                      // exception will be rethrown from here
}
catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

For more information about error handling please refer to the section *Working with exceptions*. There we also explain how to handle error conditions without having to rely on exception.

Writing components

A component in *HPX* is a C++ class which can be created remotely and for which its member functions can be invoked remotely as well. The following sections highlight how components can be defined, created, and used.

Defining components

In order for a C++ class type to be managed remotely in *HPX*, the type must be derived from the `hpx::components::component_base` template type. We call such C++ class types 'components'.

Note that the component type itself is passed as a template argument to the base class:

```
// header file some_component.hpp

#include <hpx/include/components.hpp>

namespace app
{
    // Define a new component type 'some_component'
    struct some_component
      : hpx::components::component_base<some_component>
    {
        // This member function is has to be invoked remotely
        int some_member_function(std::string const& s)
        {
            return std::stoi(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
```

(continues on next page)

(continued from previous page)

```
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function, some_member_
↪action);
    };
}

// This will generate the necessary boiler-plate code for the action allowing
// it to be invoked remotely. This declaration macro has to be placed in the
// header file defining the component itself.
//
// Note: The second argument to the macro below has to be systemwide-unique
//       C++ identifiers
//
HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_component_
↪some_action);
```

There is more boiler plate code which has to be placed into a source file in order for the component to be usable. Every component type is required to have macros placed into its source file, one for each component type and one macro for each of the actions defined by the component type.

For instance:

```
// source file some_component.cpp

#include "some_component.hpp"

// The following code generates all necessary boiler plate to enable the
// remote creation of 'app::some_component' instances with 'hpx::new_<>()'
//
using some_component = app::some_component;
using some_component_type = hpx::components::component<some_component>;

// Please note that the second argument to this macro must be a
// (system-wide) unique C++-style identifier (without any namespaces)
//
HPX_REGISTER_COMPONENT(some_component_type, some_component);
```

Note

When C++26 reflection is enabled (`HPX_WITH_CXX26_REFLECTION=ON`), the second argument to *HPX_REGISTER_COMPONENT* can be omitted. The component name is then derived automatically from the server type via `std::meta::identifier_of`:

```
// With C++26 reflection -- single argument, name derived automatically
HPX_REGISTER_COMPONENT(some_component_type)
```

The derived name is fully qualified (includes enclosing namespaces) and is equivalent to the explicit two-argument form. Explicit names always take precedence over reflection-derived ones.

> // The parameters for this macro have to be the same as used in the corresponding // HPX_REGISTER_ACTION_DECLARATION() macro invocation in the corresponding // header file. // // Please note that the second argument to this macro must be a // (system-wide) unique C++-style identifier (without any namespaces) // HPX_REGISTER_ACTION(app::some_component::some_member_action,

```
        some_component_some_action);
```

Defining client side representation classes

Often it is very convenient to define a separate type for a component which can be used on the client side (from where the component is instantiated and used). This step might seem as unnecessary duplicating code, however it significantly increases the type safety of the code.

A possible implementation of such a client side representation for the component described in the previous section could look like:

```
#include <hpx/include/components.hpp>

namespace app
{
    // Define a client side representation type for the component type
    // 'some_component' defined in the previous section.
    //
    struct some_component_client
      : hpx::components::client_base<some_component_client, some_component>
    {
        using base_type = hpx::components::client_base<
                some_component_client, some_component>;

        some_component_client(hpx::future<hpx::id_type> && id)
          : base_type(std::move(id))
        {}

        hpx::future<int> some_member_function(std::string const& s)
        {
            some_component::some_member_action act;
            return hpx::async(act, get_id(), s);
        }
    };
}
```

A client side object stores the global id of the component instance it represents. This global id is accessible by calling the function `client_base<>::get_id()`. The special constructor which is provided in the example allows to create this client side object directly using the API function *hpx::new_*.

Creating component instances

Instances of defined component types can be created in two different ways. If the component to create has a defined client side representation type, then this can be used, otherwise use the server type.

The following examples assume that `some_component_type` is the type of the server side implementation of the component to create. All additional arguments (see `, ...` notation below) are passed through to the corresponding constructor calls of those objects:

```
// create one instance on the given locality
hpx::id_type here = hpx::find_here();
```

(continues on next page)

(continued from previous page)

```
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = find_here();
hpx::future<std::vector<hpx::id_type>> f =
    hpx::new_<some_component_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
hpx::future<std::vector<hpx::id_type>> f = hpx::new_<some_component_type[]>(
    hpx::binpacking(hpx::find_all_localities()), num, ...);
```

The examples below demonstrate the use of the same API functions for creating client side representation objects (instead of just plain ids). These examples assume that `client_type` is the type of the client side representation of the component type to create. As above, all additional arguments (see `, ...` notation below) are passed through to the corresponding constructor calls of the server side implementation objects corresponding to the `client_type`:

```
// create one instance on the given locality
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<std::vector<client_type>> f =
    hpx::new_<client_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
hpx::future<std::vector<client_type>> f = hpx::new_<client_type[]>(
    hpx::binpacking(hpx::find_all_localities()), num, ...);
```

Using component instances

After having created the component instances as described above, we can simply use them as indicated below:

```
#include <hpx/include/components.hpp>
#include <iostream>
#include <vector>

// Define a simple component
struct some_component : hpx::components::component_base<some_component>
{
    void print() const
    {
        std::cout << "Hello from component instance!" << std::endl;
    }
    HPX_DEFINE_COMPONENT_ACTION(some_component, print, print_action);
};

typedef some_component::print_action print_action;

// Create one instance on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f1 =
    hpx::new_<some_component>(here);

// Get the future value
hpx::id_type instance_id = f1.get();

// Invoke action on the instance
hpx::async<print_action>(instance_id).get();

// Create multiple instances on the given locality
int num = 3;
hpx::future<std::vector<hpx::id_type>> f2 =
    hpx::new_<some_component[]>(here, num);

// Get the future value
std::vector<hpx::id_type> instance_ids = f2.get();

// Invoke action on each instance
for (const auto& id : instance_ids)
{
    hpx::async<print_action>(id).get();
}
```

We can use the component instances with distribution policies the same way.

Segmented containers

In parallel programming, there is now a plethora of solutions aimed at implementing “partially contiguous” or segmented data structures, whether on shared memory systems or distributed memory systems. *HPX* implements such structures by drawing inspiration from Standard C++ containers.

Using segmented containers

A segmented container is a template class that is described in the namespace `hpx`. All segmented containers are very similar semantically to their sequential counterpart (defined in `namespace std` but with an additional template parameter named `DistPolicy`). The distribution policy is an optional parameter that is passed last to the segmented container constructor (after the container size when no default value is given, after the default value if not). The distribution policy describes the manner in which a container is segmented and the placement of each segment among the available runtime localities.

However, only a part of the `std` container member functions were reimplemented:

- `(constructor)`, `(destructor)`, `operator=`
- `operator[]`
- `begin`, `cbegin`, `end`, `cend`
- `size`

An example of how to use the `partitioned_vector` container would be:

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

// By default, the number of segments is equal to the current number of
// localities
//
hpx::partitioned_vector<double> va(50);
hpx::partitioned_vector<double> vb(50, 0.0);
```

An example of how to use the `partitioned_vector` container with distribution policies would be:

```
#include <hpx/include/partitioned_vector.hpp>
#include <hpx/modules/runtime_distributed.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

std::size_t num_segments = 10;
std::vector<hpx::id_type> locs = hpx::find_all_localities();

auto layout =
        hpx::container_layout( num_segments, locs );
```

(continues on next page)

(continued from previous page)

```
// The number of segments is 10 and those segments are spread across the
// localities collected in the variable locs in a Round-Robin manner
//
hpx::partitioned_vector<double> va(50, layout);
hpx::partitioned_vector<double> vb(50, 0.0, layout);
```

By definition, a segmented container must be accessible from any thread although its construction is synchronous only for the thread who has called its constructor. To overcome this problem, it is possible to assign a symbolic name to the segmented container:

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

hpx::future<void> fserver = hpx::async(
  [](){
    hpx::partitioned_vector<double> v(50);

    // Register the 'partitioned_vector' with the name "some_name"
    //
    v.register_as("some_name");

    /* Do some code  */
  });

hpx::future<void> fclient =
  hpx::async(
    [](){
      // Naked 'partitioned_vector'
      //
      hpx::partitioned_vector<double> v;

      // Now the variable v points to the same 'partitioned_vector' that has
      // been registered with the name "some_name"
      //
      v.connect_to("some_name");

      /* Do some code  */
    });
```

Segmented containers

HPX provides the following segmented containers:

Table 2.23: Sequence containers

Name	Description	In header	C++ standard
`hpx::partitioned_vec`	Dynamic segmented contiguous array.	`<hpx/include/partitioned_vector.hpp>`	vector[178]

Table 2.24: Unordered associative containers

Name	Description	In header	C++ standard
`hpx::unordere`	Segmented collection of key-value pairs, hashed by keys, keys are unique.	`<hpx/include/unordered_map.hpp>`	unordered_map[179]

Segmented iterators and segmented iterator traits

The basic iterator used in the STL library is only suitable for one-dimensional structures. The iterators we use in *HPX* must adapt to the segmented format of our containers. Our iterators are then able to know when incrementing themselves if the next element of type `T` is in the same data segment or in another segment. In this second case, the iterator will automatically point to the beginning of the next segment.

Note

Note that the dereference operation `operator *` does not directly return a reference of type `T&` but an intermediate object wrapping this reference. When this object is used as an l-value, a remote write operation is performed; When this object is used as an r-value, implicit conversion to `T` type will take care of performing remote read operation.

It is sometimes useful not only to iterate element by element, but also segment by segment, or simply get a local iterator in order to avoid additional construction costs at each deferencing operations. To mitigate this need, the `hpx::traits::segmented_iterator_traits` are used.

With `segmented_iterator_traits` users can uniformly get the iterators which specifically iterates over segments (by providing a segmented iterator as a parameter), or get the local begin/end iterators of the nearest local segment (by providing a per-segment iterator as a parameter):

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<T>::iterator;
using traits   = hpx::traits::segmented_iterator_traits<iterator>;
```

(continues on next page)

[178] http://en.cppreference.com/w/cpp/container/vector
[179] http://en.cppreference.com/w/cpp/container/unordered_map

(continued from previous page)

```
hpx::partitioned_vector<T> v;
std::size_t count = 0;

auto seg_begin = traits::segment(v.begin());
auto seg_end   = traits::segment(v.end());

// Iterate over segments
for (auto seg_it = seg_begin; seg_it != seg_end; ++seg_it)
{
    auto loc_begin = traits::begin(seg_it);
    auto loc_end   = traits::end(seg_it);

    // Iterate over elements inside segments
    for (auto lit = loc_begin; lit != loc_end; ++lit, ++count)
    {
        *lit = count;
    }
}
```

Which is equivalent to:

```
hpx::partitioned_vector<T> v;
std::size_t count = 0;

auto begin = v.begin();
auto end   = v.end();

for (auto it = begin; it != end; ++it, ++count)
{
    *it = count;
}
```

Using views

The use of multidimensional arrays is quite common in the numerical field whether to perform dense matrix operations or to process images. It exist many libraries which implement such object classes overloading their basic operators (e.g. +, -, *, (), etc.). However, such operation becomes more delicate when the underlying data layout is segmented or when it is mandatory to use optimized linear algebra subroutines (i.e. BLAS subroutines).

Our solution is thus to relax the level of abstraction by allowing the user to work not directly on n-dimensionnal data, but on "n-dimensionnal collections of 1-D arrays". The use of well-accepted techniques on contiguous data is thus preserved at the segment level, and the composability of the segments is made possible thanks to multidimensional array-inspired access mode.

Preface: Why SPMD?

Although *HPX* refutes by design this programming model, the *locality* plays a dominant role when it comes to implement vectorized code. To maximize local computations and avoid unneeded data transfers, a parallel section (or Single Programming Multiple Data section) is required. Because the use of global variables is prohibited, this parallel section is created via the RAII idiom.

To define a parallel section, simply write an action taking a `spmd_block` variable as a first parameter:

```
#include <hpx/modules/collectives.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */)
{
    // Parallel section

    /* Do some code */
}
HPX_PLAIN_ACTION(bulk_function, bulk_action);
```

Note

In the following paragraphs, we will use the term "image" several times. An image is defined as a lightweight process whose entry point is a function provided by the user. It's an "image of the function".

The `spmd_block` class contains the following methods:

- Team information: `get_num_images`, `this_image`, `images_per_locality`
- Control statements: `sync_all`, `sync_images`

Here is a sample code summarizing the features offered by the `spmd_block` class:

```
#include <hpx/modules/collectives.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */)
{
    std::size_t num_images = block.get_num_images();
    std::size_t this_image = block.this_image();
    std::size_t images_per_locality = block.images_per_locality();

    /* Do some code */

    // Synchronize all images in the team
    block.sync_all();

    /* Do some code */

    // Synchronize image 0 and image 1
    block.sync_images(0,1);

    /* Do some code */

    std::vector<std::size_t> vec_images = {2,3,4};
```

(continues on next page)

(continued from previous page)

```
    // Synchronize images 2, 3 and 4
    block.sync_images(vec_images);

    // Alternative call to synchronize images 2, 3 and 4
    block.sync_images(vec_images.begin(), vec_images.end());

    /* Do some code */

    // Non-blocking version of sync_all()
    hpx::future<void> event =
        block.sync_all(hpx::launch::async);

    // Callback waiting for 'event' to be ready before being scheduled
    hpx::future<void> cb =
        event.then(
          [](hpx::future<void>)
          {

            /* Do some code */

          });

    // Finally wait for the execution tree to be finished
    cb.get();
}
HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);
```

Then, in order to invoke the parallel section, call the function `define_spmd_block` specifying an arbitrary symbolic name and indicating the number of images per *locality* to create:

```
void bulk_function(hpx::lcos::spmd_block block, /* , arg0, arg1, ... */)
{

}
HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);

int main()
{
    /* std::size_t arg0, arg1, ...; */

    bulk_action act;
    std::size_t images_per_locality = 4;

    // Instantiate the parallel section
    hpx::lcos::define_spmd_block(
        "some_name", images_per_locality, std::move(act) /*, arg0, arg1, ... */);

    return 0;
}
```

> **Note**
>
> In principle, the user should never call the `spmd_block` constructor. The `define_spmd_block` function is responsible of instantiating `spmd_block` objects and broadcasting them to each created image.

SPMD multidimensional views

Some classes are defined as "container views" when the purpose is to observe and/or modify the values of a container using another perspective than the one that characterizes the container. For example, the values of an `std::vector` object can be accessed via the expression `[i]`. Container views can be used, for example, when it is desired for those values to be "viewed" as a 2D matrix that would have been flattened in a `std::vector`. The values would be possibly accessible via the expression `vv(i,j)` which would call internally the expression `v[k]`.

By default, the `partitioned_vector` class integrates 1-D views of its segments:

```
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<double>::iterator;
using traits   = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<double> v;

// Create a 1-D view of the vector of segments
auto vv = traits::segment(v.begin());

// Access segment i
std::vector<double> v = vv[i];
```

Our views are called "multidimensional" in the sense that they generalize to N dimensions the purpose of `segmented_iterator_traits::segment()` in the 1-D case. Note that in a parallel section, the 2-D expression `a(i,j) = b(i,j)` is quite confusing because without convention, each of the images invoked will race to execute the statement. For this reason, our views are not only multidimensional but also "spmd-aware".

> **Note**
>
> SPMD-awareness: The convention is simple. If an assignment statement contains a view subscript as an l-value, it is only and only the image holding the r-value who is evaluating the statement. (In MPI sense, it is called a Put operation).

Subscript-based operations

Here are some examples of using subscripts in the 2-D view case:

```
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

using Vec = hpx::partitioned_vector<double>;
using View_2D = hpx::partitioned_vector_view<double,2>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t height, width;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {height,width});

    // The l-value is a view subscript, the image that owns vv(1,0)
    // evaluates the assignment.
    vv(0,1) = vv(1,0);

    // The l-value is a view subscript, the image that owns the r-value
    // (result of expression 'std::vector<double>(4,1.0)') evaluates the
    // assignment : oops! race between all participating images.
    vv(2,3) = std::vector<double>(4,1.0);
}
```

Iterator-based operations

Here are some examples of using iterators in the 3-D view case:

```
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(int);

using Vec = hpx::partitioned_vector<int>;
using View_3D = hpx::partitioned_vector_view<int,3>;

/* Do some code */
```

(continues on next page)

(continued from previous page)

```
Vec v1, v2;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t sixe_x, size_y, size_z;

    // Instantiate the views
    View_3D vv1(block, v1.begin(), v1.end(), {sixe_x,size_y,size_z});
    View_3D vv2(block, v2.begin(), v2.end(), {sixe_x,size_y,size_z});

    // Save previous segments covered by vv1 into segments covered by vv2
    auto vv2_it = vv2.begin();
    auto vv1_it = vv1.cbegin();

    for(; vv2_it != vv2.end(); vv2_it++, vv1_it++)
    {
        // It's a Put operation
        *vv2_it = *vv1_it;
    }

    // Ensure that all images have performed their Put operations
    block.sync_all();

    // Ensure that only one image is putting updated data into the different
    // segments covered by vv1
    if(block.this_image() == 0)
    {
        int idx = 0;

        // Update all the segments covered by vv1
        for(auto i = vv1.begin(); i != vv1.end(); i++)
        {
            // It's a Put operation
            *i = std::vector<float>(elt_size,idx++);
        }
    }
}
```

Here is an example that shows how to iterate only over segments owned by the current image:

```
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/components/containers/partitioned_vector/partitioned_vector_local_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_1D = hpx::partitioned_vector_view<float,1>;
```

(continues on next page)

(continued from previous page)

```
/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t num_segments;

    // Instantiate the view
    View_1D vv(block, v.begin(), v.end(), {num_segments});

    // Instantiate the local view from the view
    auto local_vv = hpx::local_view(vv);

    for ( auto i = local_vv.begin(); i != local_vv.end(); i++ )
    {
        std::vector<float> & segment = *i;

        /* Do some code */
    }

}
```

Instantiating sub-views

It is possible to construct views from other views: we call it sub-views. The constraint nevertheless for the subviews is to retain the dimension and the value type of the input view. Here is an example showing how to create a sub-view:

```
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_2D = hpx::partitioned_vector_view<float,2>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t N = 20;
    std::size_t tilesize = 5;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {N,N});
```

(continues on next page)

(continued from previous page)

```
    // Instantiate the subview
    View_2D svv(
        block,&vv(tilesize,0),&vv(2*tilesize-1,tilesize-1),{tilesize,tilesize},{N,N});

    if(block.this_image() == 0)
    {
        // Equivalent to 'vv(tilesize,0) = 2.0f'
        svv(0,0) = 2.0f;

        // Equivalent to 'vv(2*tilesize-1,tilesize-1) = 3.0f'
        svv(tilesize-1,tilesize-1) = 3.0f;
    }

}
```

Note

The last parameter of the subview constructor is the size of the original view. If one would like to create a subview of the subview and so on, this parameter should stay unchanged. `{N,N}` for the above example).

C++ co-arrays

Fortran has extended its scalar element indexing approach to reference each segment of a distributed array. In this extension, a segment is attributed a ?co-index? and lives in a specific *locality*. A co-index provides the application with enough information to retrieve the corresponding data reference. In C++, containers present themselves as a ?smarter? alternative of Fortran arrays but there are still no corresponding standardized features similar to the Fortran co-indexing approach. We present here an implementation of such features in *HPX*.

Preface: co-array, a segmented container tied to a SPMD multidimensional views

As mentioned before, a co-array is a distributed array whose segments are accessible through an array-inspired access mode. We have previously seen that it is possible to reproduce such access mode using the concept of views. Nevertheless, the user must pre-create a segmented container to instantiate this view. We illustrate below how a single constructor call can perform those two operations:

```
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/modules/collectives.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'
//
HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;

    std::size_t height=32, width=4, segment_size=10;
```

(continues on next page)

(continued from previous page)

```
    hpx::coarray<double,3> a(block, "a", {height,width,_}, segment_size);

    /* Do some code */
}
```

Unlike segmented containers, a co-array object can only be instantiated within a parallel section. Here is the description of the parameters to provide to the coarray constructor:

Table 2.25: Parameters of coarray constructor

Parameter	Description
`block`	Reference to a `spmd_block` object
`"a"`	Symbolic name of type `std::string`
`{height,width, _}`	Dimensions of the `coarray` object
`segment_size`	Size of a co-indexed element (i.e. size of the object referenced by the expression `a(i,j,k)`)

Note that the "last dimension size" cannot be set by the user. It only accepts the constexpr variable `hpx::container::placeholders::_`. This size, which is considered private, is equal to the number of current images (value returned by `block.get_num_images()`).

Note

An important constraint to remember about coarray objects is that all segments sharing the same "last dimension index" are located in the same image.

Using co-arrays

The member functions owned by the `coarray` objects are exactly the same as those of spmd multidimensional views. These are:

```
* Subscript-based operations
* Iterator-based operations
```

However, one additional functionality is provided. Knowing that the element `a(i,j,k)` is in the memory of the `k`th image, the use of local subscripts is possible.

Note

For spmd multidimensional views, subscripts are only global as it still involves potential remote data transfers.

Here is an example of using local subscripts:

```
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/modules/collectives.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'
```

(continues on next page)

(continued from previous page)

```
//
HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;

    std::size_t height=32, width=4, segment_size=10;

    hpx::coarray<double,3> a(block, "a", {height,width,_}, segment_size);

    double idx = block.this_image()*height*width;

    for (std::size_t j = 0; j<width; j++)
    for (std::size_t i = 0; i<height; i++)
    {
        // Local write operation performed via the use of local subscript
        a(i,j,_) = std::vector<double>(elt_size,idx);
        idx++;
    }

    block.sync_all();
}
```

Note

When the "last dimension index" of a subscript is equal to `hpx::container::placeholders::_`, local subscript (and not global subscript) is used. It is equivalent to a global subscript used with a "last dimension index" equal to the value returned by `block.this_image()`.

2.4.13 Running on batch systems

This section walks you through launching *HPX* applications on various batch systems.

How to use *HPX* applications with PBS

Most *HPX* applications are executed on parallel computers. These platforms typically provide integrated job management services that facilitate the allocation of computing resources for each parallel program. *HPX* includes support for one of the most common job management systems, the Portable Batch System (PBS).

All PBS jobs require a script to specify the resource requirements and other parameters associated with a parallel job. The PBS script is basically a shell script with PBS directives placed within commented sections at the beginning of the file. The remaining (not commented-out) portions of the file executes just like any other regular shell script. While the description of all available PBS options is outside the scope of this tutorial (the interested reader may refer to in-depth documentation[180] for more information), below is a minimal example to illustrate the approach. The following test application will use the multithreaded `hello_world_distributed` program, explained in the section *Remote execution with actions*.

[180] http://www.clusterresources.com/torquedocs21/

```
#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

Caution

If the first application specific argument (inside `$APP_OPTIONS`) is a non-option (i.e., does not start with a `-` or a `--`), then the argument has to be placed before the option *--hpx:nodes*, which, in this case, should be the last option on the command line.

Alternatively, use the option *--hpx:endnodes* to explicitly mark the end of the list of node names:

```
$ pbsdsh -u $APP_PATH --hpx:nodes`cat $PBS_NODEFILE` --hpx:endnodes $APP_OPTIONS
```

The `#PBS -l nodes=2:ppn=4` directive will cause two compute nodes to be allocated for the application, as specified in the option `nodes`. Each of the nodes will dedicate four cores to the program, as per the option `ppn`, short for "processors per node" (PBS does not distinguish between processors and cores). Note that requesting more cores per node than physically available is pointless and may prevent PBS from accepting the script.

On newer PBS versions the PBS command syntax might be different. For instance, the PBS script above would look like:

```
#!/bin/bash
#
#PBS -l select=2:ncpus=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

`APP_PATH` and `APP_OPTIONS` are shell variables that respectively specify the correct path to the executable (`hello_world_distributed` in this case) and the command line options. Since the `hello_world_distributed` application doesn't need any command line options, `APP_OPTIONS` has been left empty. Unlike in other execution environments, there is no need to use the *--hpx:threads* option to indicate the required number of OS threads per node; the *HPX* library will derive this parameter automatically from PBS.

Finally, pbsdsh is a PBS command that starts tasks to the resources allocated to the current job. It is recommended to leave this line as shown and modify only the PBS options and shell variables as needed for a specific application.

Important

A script invoked by pbsdsh starts in a very basic environment: the user's `$HOME` directory is defined and is the current directory, the `LANG` variable is set to `C` and the `PATH` is set to the basic `/usr/local/bin:/usr/bin:/bin` as defined in a system-wide file pbs_environment. Nothing that would normally be set up by a system shell profile or user shell profile is defined, unlike the environment for the main job script.

Another choice is for the pbsdsh command in your main job script to invoke your program via a shell, like `sh` or `bash`, so that it gives an initialized environment for each instance. Users can create a small script `runme.sh`, which is used to invoke the program:

```
#!/bin/bash
# Small script which invokes the program based on what was passed on its
# command line.
#
# This script is executed by the bash shell which will initialize all
# environment variables as usual.
$@
```

Now, the script is invoked using the pbsdsh tool:

```
#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u runme.sh $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

All that remains now is submitting the job to the queuing system. Assuming that the contents of the PBS script were saved in the file `pbs_hello_world.sh` in the current directory, this is accomplished by typing:

```
$ qsub ./pbs_hello_world_pbs.sh
```

If the job is accepted, qsub will print out the assigned job ID, which may look like:

```
$ 42.supercomputer.some.university.edu
```

To check the status of your job, issue the following command:

```
$ qstat 42.supercomputer.some.university.edu
```

and look for a single-letter job status symbol. The common cases include:

- *Q* - signifies that the job is queued and awaiting its turn to be executed.
- *R* - indicates that the job is currently running.
- *C* - means that the job has completed.

The example qstat output below shows a job waiting for execution resources to become available:

```
Job id                    Name             User            Time Use S Queue
------------------------- ---------------- --------------- -------- - -----
42.supercomputer          ...ello_world.sh joe_user               0 Q batch
```

After the job completes, PBS will place two files, `pbs_hello_world.sh.o42` and `pbs_hello_world.sh.e42`, in the directory where the job was submitted. The first contains the standard output and the second contains the standard error from all the nodes on which the application executed. In our example, the error output file should be empty and the standard output file should contain something similar to:

```
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
hello world from OS-thread 1 on locality 1
```

(continues on next page)

(continued from previous page)

```
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 1
hello world from OS-thread 2 on locality 1
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 1
```

Congratulations! You have just run your first distributed *HPX* application!

How to use *HPX* applications with SLURM

Just like PBS (described in section *How to use HPX applications with PBS*), SLURM is a job management system which is widely used on large supercomputing systems. Any *HPX* application can easily be run using SLURM. This section describes how this can be done.

The easiest way to run an *HPX* application using SLURM is to utilize the command line tool srun, which interacts with the SLURM batch scheduling system:

```
$ srun -p <partition> -N <number-of-nodes> hpx-application <application-arguments>
```

Here, `<partition>` is one of the node partitions existing on the target machine (consult the machine's documentation to get a list of existing partitions) and `<number-of-nodes>` is the number of compute nodes that should be used. By default, the *HPX* application is started with one *locality* per node and uses all available cores on a node. You can change the number of localities started per node (for example, to account for NUMA effects) by specifying the `-n` option of srun. The number of cores per *locality* can be set by `-c`. The `<application-arguments>` are any application specific arguments that need to be passed on to the application.

Note

There is no need to use any of the *HPX* command line options related to the number of localities, number of threads, or related to networking ports. All of this information is automatically extracted from the SLURM environment by the *HPX* startup code.

Important

The srun documentation explicitly states: "If `-c` is specified without `-n`, as many tasks will be allocated per node as possible while satisfying the `-c` restriction. For instance on a cluster with 8 CPUs per node, a job request for 4 nodes and 3 CPUs per task may be allocated 3 or 6 CPUs per node (1 or 2 tasks per node) depending upon resource consumption by other jobs." For this reason, it's recommended to always specify `-n <number-of-instances>`, even if `<number-of-instances>` is equal to one (1).

Interactive shells

To get an interactive development shell on one of the nodes, users can issue the following command:

```
$ srun -p <node-type> -N <number-of-nodes> --pty /bin/bash -l
```

After the shell has been opened, users can run their *HPX* application. By default, it uses all available cores. Note that if you requested one node, you don't need to do `srun` again. However, if you requested more than one node, and want to run your distributed application, you can use `srun` again to start up the distributed *HPX* application. It will use the resources that have been requested for the interactive shell.

Scheduling batch jobs

The above mentioned method of running *HPX* applications is fine for development purposes. The disadvantage that comes with `srun` is that it only returns once the application is finished. This might not be appropriate for longer-running applications (for example, benchmarks or larger scale simulations). In order to cope with that limitation, users can use the sbatch command.

The `sbatch` command expects a script that it can run once the requested resources are available. In order to request resources, users need to add `#SBATCH` comments in their script or provide the necessary parameters to `sbatch` directly. The parameters are the same as with `run`. The commands you need to execute are the same you would need to start your application as if you were in an interactive shell.

2.4.14 Debugging *HPX* applications

Using a debugger with *HPX* applications

Using a debugger such as `gdb` with *HPX* applications is no problem. However, there are some things to keep in mind to make the experience somewhat more productive.

Call stacks in *HPX* can often be quite unwieldy as the library is heavily templated and the call stacks can be very deep. For this reason it is sometimes a good idea compile *HPX* in `RelWithDebInfo` mode, which applies some optimizations but keeps debugging symbols. This can often compress call stacks significantly. On the other hand, stepping through the code can also be more difficult because of statements being reordered and variables being optimized away. Also, note that because *HPX* implements user-space threads and context switching, call stacks may not always be complete in a debugger.

HPX launches not only worker threads but also a few helper threads. The first thread is the main thread, which typically does no work in an *HPX* application, except at startup and shutdown. If using the default settings, *HPX* will spawn six additional threads (used for service thread pools). The first worker thread is usually the eighth thread, and most user codes will be run on these worker threads. The last thread is a helper thread used for *HPX* shutdown.

Finally, since *HPX* is a multi-threaded runtime, the following `gdb` options can be helpful:

```
set pagination off
set non-stop on
```

Non-stop mode allows users to have a single thread stop on a breakpoint without stopping all other threads as well.

Using sanitizers with *HPX* applications

Warning

Not all parts of *HPX* are sanitizer clean. This means that users may end up with false positives from *HPX* itself when using sanitizers for their applications.

To use sanitizers with *HPX*, turn on `HPX_WITH_SANITIZERS` and turn off `HPX_WITH_STACKOVERFLOW_DETECTION` during CMake[181] configuration. It's recommended to also build Boost with the same sanitizers that will be used for *HPX*. The appropriate sanitizers can then be enabled using CMake by appending `-fsanitize=address -fno-omit-frame-pointer` to `CMAKE_CXX_FLAGS` and `-fsanitize=address` to `CMAKE_EXE_LINKER_FLAGS`. Replace `address` with the sanitizer that you want to use.

Debugging applications using core files

For *HPX* to generate useful core files, *HPX* has to be compiled without signal and exception handlers *`HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL`*. If this option is not specified, the signal handlers change the application state. For example, after a segmentation fault the stack trace will show the signal handler. Similarly, unhandled exceptions are also caught by these handlers and the stack trace will not point to the location where the unhandled exception was thrown.

In general, core files are a helpful tool to inspect the state of the application at the moment of the crash (post-mortem debugging), without the need of attaching a debugger beforehand. This approach to debugging is especially useful if the error cannot be reliably reproduced, as only a single crashed application run is required to gain potentially helpful information like a stacktrace.

To debug with core files, the operating system first has to be told to actually write them. On most Unix systems this can be done by calling:

```
$ ulimit -c unlimited
```

in the shell. Now the debugger can be started up with:

```
$ gdb <application> <core file name>
```

The debugger should now display the last state of the application. The default file name for core files is `core`.

2.4.15 Optimizing *HPX* applications

Performance counters

Performance counters in *HPX* are used to provide information as to how well the runtime system or an application is performing. The counter data can help determine system bottlenecks, and fine-tune system and application performance. The *HPX* runtime system, its networking, and other layers provide counter data that an application can consume to provide users with information about how well the application is performing.

Applications can also use counter data to determine how much system resources to consume. For example, an application that transfers data over the network could consume counter data from a network switch to determine how much data to transfer without competing for network bandwidth with other network traffic. The application could use the counter data to adjust its transfer rate as the bandwidth usage from other network traffic increases or decreases.

[181] https://www.cmake.org

Performance counters are *HPX* parallel processes that expose a predefined interface. *HPX* exposes special API functions that allow one to create, manage, and read the counter data, and release instances of performance counters. Performance Counter instances are accessed by name, and these names have a predefined structure which is described in the section *Performance counter names*. The advantage of this is that any Performance Counter can be accessed remotely (from a different *locality*) or locally (from the same *locality*). Moreover, since all counters expose their data using the same API, any code consuming counter data can be utilized to access arbitrary system information with minimal effort.

Counter data may be accessed in real time. More information about how to consume counter data can be found in the section *Consuming performance counter data*.

All *HPX* applications provide command line options related to performance counters, such as the ability to list available counter types, or periodically query specific counters to be printed to the screen or save them in a file. For more information, please refer to the section *HPX Command Line Options*.

Performance counter names

All Performance Counter instances have a name uniquely identifying each instance. This name can be used to access the counter, retrieve all related meta data, and to query the counter data (as described in the section *Consuming performance counter data*). Counter names are strings with a predefined structure. The general form of a countername is:

```
/objectname{full_instancename}/countername@parameters
```

where `full_instancename` could be either another (full) counter name or a string formatted as:

```
parentinstancename#parentindex/instancename#instanceindex
```

Each separate part of a countername (e.g., `objectname`, `countername` `parentinstancename`, `instancename`, and `parameters`) should start with a letter (`'a'`… `'z'`, `'A'`… `'Z'`) or an underscore character (`'_'`), optionally followed by letters, digits (`'0'`… `'9'`), hyphen (`'-'`), or underscore characters. Whitespace is not allowed inside a counter name. The characters `'/'`, `'{'`, `'}'`, `'#'` and `'@'` have a special meaning and are used to delimit the different parts of the counter name.

The parts `parentinstanceindex` and `instanceindex` are integers. If an index is not specified, *HPX* will assume a default of `-1`.

Two counter name examples

This section gives examples of both simple counter names and aggregate counter names. For more information on simple and aggregate counter names, please see *Performance counter instances*.

An example of a well-formed (and meaningful) simple counter name would be:

```
/threads{locality#0/total}/count/cumulative
```

This counter returns the current cumulative number of executed (retired) *HPX* threads for the *locality* `0`. The counter type of this counter is `/threads/count/cumulative` and the full instance name is `locality#0/total`. This counter type does not require an `instanceindex` or `parameters` to be specified.

In this case, the `parentindex` (the `'0'`) designates the *locality* for which the counter instance is created. The counter will return the number of *HPX* threads retired on that particular *locality*.

Another example for a well formed (aggregate) counter name is:

```
/statistics{/threads{locality#0/total}/count/cumulative}/average@500
```

This counter takes the simple counter from the first example, samples its values every `500` milliseconds, and returns the average of the value samples whenever it is queried. The counter type of this counter is `/statistics/average` and the instance name is the full name of the counter for which the values have to be averaged. In this case, the `parameters` (the `'500'`) specify the sampling interval for the averaging to take place (in milliseconds).

Performance counter types

Every performance counter belongs to a specific performance counter type which classifies the counters into groups of common semantics. The type of a counter is identified by the `objectname` and the `countername` parts of the name.

```
/objectname/countername
```

When an application starts *HPX* will register all available counter types on each of the localities. These counter types are held in a special performance counter registration database, which can be used to retrieve the meta data related to a counter type and to create counter instances based on a given counter instance name.

Performance counter instances

The `full_instancename` distinguishes different counter instances of the same counter type. The formatting of the `full_instancename` depends on the counter type. There are two types of counters: simple counters, which usually generate the counter values based on direct measurements, and aggregate counters, which take another counter and transform its values before generating their own counter values. An example for a simple counter is given *above*: counting retired *HPX* threads. An aggregate counter is shown as an example *above* as well: calculating the average of the underlying counter values sampled at constant time intervals.

While simple counters use instance names formatted as `parentinstancename#parentindex/instancename#instanceindex`, most aggregate counters have the full counter name of the embedded counter as their instance name.

Not all simple counter types require specifying all four elements of a full counter instance name; some of the parts (`parentinstancename`, `parentindex`, `instancename`, and `instanceindex`) are optional for specific counters. Please refer to the documentation of a particular counter for more information about the formatting requirements for the name of this counter (see *Existing HPX performance counters*).

The `parameters` are used to pass additional information to a counter at creation time. They are optional, and they fully depend on the concrete counter. Even if a specific counter type allows additional parameters to be given, those usually are not required as sensible defaults will be chosen. Please refer to the documentation of a particular counter for more information about what parameters are supported, how to specify them, and what default values are assumed (see also *Existing HPX performance counters*).

Every *locality* of an application exposes its own set of performance counter types and performance counter instances. The set of exposed counters is determined dynamically at application start based on the execution environment of the application. For instance, this set is influenced by the current hardware environment for the *locality* (such as whether the *locality* has access to accelerators), and the software environment of the application (such as the number of OS threads used to execute *HPX* threads).

Using wildcards in performance counter names

It is possible to use wildcard characters when specifying performance counter names. Performance counter names can contain two types of wildcard characters:

- Wildcard characters in the performance counter type
- Wildcard characters in the performance counter instance name

A wildcard character has a meaning which is very close to usual file name wildcard matching rules implemented by common shells (like bash).

Table 2.26: Wildcard characters in the performance counter type

Wildcard	Description
`*`	This wildcard character matches any number (zero or more) of arbitrary characters.
`?`	This wildcard character matches any single arbitrary character.
`[...]`	This wildcard character matches any single character from the list of specified within the square brackets.

Table 2.27: Wildcard characters in the performance counter instance name

Wildcard	Description
`*`	This wildcard character matches any *locality* or any thread, depending on whether it is used for `locality#*` or `worker-thread#*`. No other wildcards are allowed in counter instance names.

Consuming performance counter data

You can consume performance data using either the command line interface, the *HPX* application or the *HPX* API. The command line interface is easier to use, but it is less flexible and does not allow one to adjust the behaviour of your application at runtime. The command line interface provides a convenience abstraction but simplified abstraction for querying and logging performance counter data for a set of performance counters.

Consuming performance counter data from the command line

HPX provides a set of predefined command line options for every application that uses `hpx::init` for its initialization. While there are many more command line options available (see *HPX Command Line Options*), the set of options related to performance counters allows one to list existing counters, and query existing counters once at application termination or repeatedly after a constant time interval.

The following table summarizes the available command line options:

Table 2.28: *HPX* Command Line Options Related to Performance Counters

Command line option	Description
`--hpx:pr`	Prints the specified performance counter either repeatedly and/or at the times specified by `--hpx:print-counter-at` (see also option `--hpx:print-counter-interval`).
`--hpx:pr`	Prints the specified performance counter either repeatedly and/or at the times specified by `--hpx:print-counter-at`. Reset the counter after the value is queried (see also option `--hpx:print-counter-interval`).
`--hpx:pr`	Prints the performance counter(s) specified with `--hpx:print-counter` repeatedly after the time interval (specified in milliseconds) (default:`0` which means print once at shutdown).
`--hpx:pr`	Prints the performance counter(s) specified with `--hpx:print-counter` to the given file (default: console).
`--hpx:li`	Lists the names of all registered performance counters.
`--hpx:li`	Lists the description of all registered performance counters.
`--hpx:pr`	Prints the performance counter(s) specified with `--hpx:print-counter`. Possible formats in CVS format with header or without any header (see option `--hpx:no-csv-header`), possible values: `csv` (prints counter values in CSV format with full names as header) `csv-short` (prints counter values in CSV format with shortnames provided with `--hpx:print-counter` as `--hpx:print-counter shortname,full-countername`).
`--hpx:no`	Prints the performance counter(s) specified with `--hpx:print-counter` and `csv` or `csv-short` format specified with `--hpx:print-counter-format` without header.
`--hpx:pr arg`	Prints the performance counter(s) specified with `--hpx:print-counter` (or `--hpx:print-counter-reset`) at the given point in time. Possible argument values: `startup`, `shutdown` (default), `noshutdown`.
`--hpx:re`	Resets all performance counter(s) specified with `--hpx:print-counter` after they have been evaluated.
`--hpx:pr`	Appends counter type description to generated output.
`--hpx:pr`	Each locality prints only its own local counters.

While the options `--hpx:list-counters` and `--hpx:list-counter-infos` give a short list of all available counters, the full documentation for those can be found in the section *Existing HPX performance counters*.

HPX-Top

HPX-Top is a real-time, terminal-based dashboard designed for monitoring the health and performance of distributed *HPX* applications. Inspired by tools like `htop` and `btop`, it provides a high-level overview of system utilization, network flow, and internal runtime metrics.

Fig. 2.9: HPX-Top Real-time Performance Dashboard

Features

- **Locality-Aware Monitoring**: Automatically detects and displays metrics for all localities in a running distributed application.
- **Thread Pool Utilization**: Visualizes real-time usage of worker threads with instantaneous counts and historical sparkline graphs.
- **Parcel Throughput**: Tracks incoming and outgoing parcels, helping to identify network-bound bottlenecks or communication hotspots.
- **AGAS Health Monitor**: Displays cache hit and miss rates for the Application Global Address Space (AGAS), crucial for diagnosing naming service bottlenecks.

Usage

HPX-Top is implemented as a Python script that acts as a wrapper around your *HPX* application. It automatically configures the necessary performance counters and output formats.

The tool requires the `rich` Python library for rendering the terminal UI:

```
$ pip install rich
```

To monitor an *HPX* application, launch it through `hpx-top.py`:

```
$ python3 tools/hpx-top.py ./your_application --hpx:threads=4 [other HPX flags]
```

You can also run HPX-Top in mock mode to explore the interface without a running *HPX* application:

```
$ python3 tools/hpx-top.py --mock
```

Technical Details

The tool leverages *HPX*'s built-in performance counter framework. It launches the target application with specific flags (`--hpx:print-counter-interval` and `--hpx:print-counter-format=csv-short`) and parses the standard output in a non-blocking background thread to update the TUI.

HPX Smart Telemetry (hpx_stat_viewer)

HPX Smart Telemetry (`hpx_stat_viewer.py`) is an intelligent, lightweight performance dashboard designed to identify performance anomalies in real-time. While `hpx-top` provides a broad system overview, `hpx_stat_viewer` focuses on deep-dive analysis of specific metrics with built-in heuristic alerting.

Fig. 2.10: HPX Smart Telemetry Dashboard with Anomaly Detection

Features

- **Heuristic Anomaly Detection**: Uses an Exponential Moving Average (EMA) to monitor counter trends. It automatically flags sudden spikes (+150%) or drops (-60%) with prominent visual alerts like `[ SPIKE]` and `[ DROP]`.
- **Live History Sparklines**: Displays 10-tick historical trend graphs next to every metric, helping developers distinguish between momentary noise and persistent bottlenecks.
- **Smart Filtering and Grouping**: Supports regex-based counter filtering and automatically groups metrics by locality for large-scale distributed runs.
- **Zero-Dependency Core**: Requires no external TUI libraries, making it highly portable for various terminal environments.

Usage

`hpx_stat_viewer.py` reads HPX counter data from standard input in `csv-short` transient format. This allows it to be used for both live monitoring and post-mortem analysis of log files.

To monitor a live application with smart filtering:

```
$ ./your_hpx_app --hpx:print-counter-interval=500 --hpx:print-counter-format=csv-short ... | \
  python3 tools/hpx_stat_viewer.py --filter "threads|utilization"
```

To replay an offline performance log for analysis:

```
$ python3 tools/hpx_stat_viewer.py --replay your_hpx_counters.csv --speed 0.5
```

Technical Details

The dashboard implements a thread-safe parser that handles HPX's CSV-short format. The anomaly detection engine uses a smoothing factor of 0.4 for its EMA calculations, balancing responsiveness with stability. It is officially integrated into the HPX installation rules under the `tools` component.

A simple example

All of the commandline options mentioned above can be tested using the `hello_world_distributed` example.

Listing all available counters `hello_world_distributed --hpx:list-counters` yields:

```
List of available counter instances (replace * below with the appropriate
sequence number)
-------------------------------------------------------------------------
/agas/count/allocate /agas/count/bind /agas/count/bind_gid
/agas/count/bind_name ... /threads{locality#*/allocator#*}/count/objects
/threads{locality#*/total}/count/stack-recycles
/threads{locality#*/total}/idle-rate
/threads{locality#*/worker-thread#*}/idle-rate
```

Providing more information about all available counters, `hello_world_distributed --hpx:list-counter-infos` yields:

```
Information about available counter instances (replace * below with the
appropriate sequence number)
------------------------------------------------------------------------------
fullname: /agas/count/allocate helptext: returns the number of invocations of
the AGAS service 'allocate' type: counter_type::raw version: 1.0.0
------------------------------------------------------------------------------

------------------------------------------------------------------------------
fullname: /agas/count/bind helptext: returns the number of invocations of the
AGAS service 'bind' type: counter_type::raw version: 1.0.0
------------------------------------------------------------------------------

------------------------------------------------------------------------------
fullname: /agas/count/bind_gid helptext: returns the number of invocations of
the AGAS service 'bind_gid' type: counter_type::raw version: 1.0.0
------------------------------------------------------------------------------

...
```

This command will not only list the counter names but also a short description of the data exposed by this counter.

> **Note**
>
> The list of available counters may differ depending on the concrete execution environment (hardware or software) of your application.

Requesting the counter data for one or more performance counters can be achieved by invoking `hello_world_distributed` with a list of counter names:

```
$ hello_world_distributed \
    --hpx:print-counter=/threads{locality#0/total}/count/cumulative \
    --hpx:print-counter=/agas{locality#0/total}/count/bind
```

which yields for instance:

```
hello world from OS-thread 0 on locality 0
/threads{locality#0/total}/count/cumulative,1,0.212527,[s],33
/agas{locality#0/total}/count/bind,1,0.212790,[s],11
```

The first line is the normal output generated by `hello_world_distributed` and has no relation to the counter data listed. The last two lines contain the counter data as gathered at application shutdown. These lines have six fields, the counter name, the sequence number of the counter invocation, the time stamp at which this information has been sampled, the unit of measure for the time stamp, the actual counter value and an optional unit of measure for the counter value.

Note

The command line option `--hpx:print-counter-types` will append a seventh field to the generated output. This field will hold an abbreviated counter type.

The actual counter value can be represented by a single number (for counters returning singular values) or a list of numbers separated by `':'` (for counters returning an array of values, like for instance a histogram).

Note

The name of the performance counter will be enclosed in double quotes `'"'` if it contains one or more commas `','`.

Requesting to query the counter data once after a constant time interval with this command line:

```
$ hello_world_distributed \
    --hpx:print-counter=/threads{locality#0/total}/count/cumulative \
    --hpx:print-counter=/agas{locality#0/total}/count/bind \
    --hpx:print-counter-interval=20
```

yields for instance (leaving off the actual console output of the `hello_world_distributed` example for brevity):

```
threads{locality#0/total}/count/cumulative,1,0.002409,[s],22
agas{locality#0/total}/count/bind,1,0.002542,[s],9
threads{locality#0/total}/count/cumulative,2,0.023002,[s],41
agas{locality#0/total}/count/bind,2,0.023557,[s],10
threads{locality#0/total}/count/cumulative,3,0.037514,[s],46
agas{locality#0/total}/count/bind,3,0.038679,[s],10
```

The command `--hpx:print-counter-destination=<file>` will redirect all counter data gathered to the specified file name, which avoids cluttering the console output of your application.

The command line option `--hpx:print-counter` supports using a limited set of wildcards for a (very limited) set of use cases. In particular, all occurrences of `#*` as in `locality#*` and in `worker-thread#*` will be automatically expanded to the proper set of performance counter names representing the actual environment for the executed program. For instance, if your program is utilizing four worker threads for the execution of *HPX* threads (see command line option *--hpx:threads*) the following command line

```
$ hello_world_distributed \
    --hpx:threads=4 \
    --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative
```

will print the value of the performance counters monitoring each of the worker threads:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.0025214,[s],27
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.0025453,[s],33
/threads{locality#0/worker-thread#2}/count/cumulative,1,0.0025683,[s],29
/threads{locality#0/worker-thread#3}/count/cumulative,1,0.0025904,[s],33
```

The command `--hpx:print-counter-format` takes values `csv` and `csv-short` to generate CSV formatted counter values with a header.

With format as csv:

```
$ hello_world_distributed \
    --hpx:threads=2 \
    --hpx:print-counter-format csv \
    --hpx:print-counter /threads{locality#*/total}/count/cumulative \
    --hpx:print-counter /threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the full countername as a header:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
/threads{locality#*/total}/count/cumulative,/threads{locality#*/total}/count/cumulative-
↪phases
39,93
```

With format csv-short:

```
$ hello_world_distributed \
    --hpx:threads 2 \
    --hpx:print-counter-format csv-short \
    --hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
    --hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the short countername as a header:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
cumulative,phases
39,93
```

With format csv and csv-short when used with `--hpx:print-counter-interval`:

```
$ hello_world_distributed \
    --hpx:threads 2 \
    --hpx:print-counter-format csv-short \
    --hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
    --hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases \
    --hpx:print-counter-interval 5
```

will print the header only once repeating the performance counter value(s) repeatedly:

```
cum,phases
25,42
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
44,95
```

The command `--hpx:no-csv-header` can be used with `--hpx:print-counter-format` to print performance counter values in CSV format without any header:

```
$ hello_world_distributed \
--hpx:threads 2 \
--hpx:print-counter-format csv-short \
--hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
--hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases \
--hpx:no-csv-header
```

will print:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
37,91
```

Consuming performance counter data using the *HPX* API

HPX provides an API that allows users to discover performance counters and to retrieve the current value of any existing performance counter from any application.

Discover existing performance counters

Retrieve the current value of any performance counter

Performance counters are specialized *HPX* components. In order to retrieve a counter value, the performance counter needs to be instantiated. *HPX* exposes a client component object for this purpose:

```
hpx::performance_counters::performance_counter counter(std::string const& name);
```

Instantiating an instance of this type will create the performance counter identified by the given `name`. Only the first invocation for any given counter name will create a new instance of that counter. All following invocations for a given counter name will reference the initially created instance. This ensures that at any point in time there is never more than one active instance of any of the existing performance counters.

In order to access the counter value (or to invoke any of the other functionality related to a performance counter, like `start`, `stop` or `reset`) member functions of the created client component instance should be called:

```
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count(
    "/threads{locality#0/total}/count/cumulative");
hpx::cout << count.get_value<int>().get() << std::endl;
```

For more information about the client component type, see `hpx::performance_counters::performance_counter`

Note

In the above example `count.get_value()` returns a future. In order to print the result we must append `.get()` to retrieve the value. You could write the above example like this for more clarity:

```
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count(
    "/threads{locality#0/total}/count/cumulative");
hpx::future<int> result = count.get_value<int>();
hpx::cout << result.get() << std::endl;
```

Providing performance counter data

HPX offers several ways by which you may provide your own data as a performance counter. This has the benefit of exposing additional, possibly application-specific information using the existing Performance Counter framework, unifying the process of gathering data about your application.

An application that wants to provide counter data can implement a performance counter to provide the data. When a consumer queries performance data, the *HPX* runtime system calls the provider to collect the data. The runtime system uses an internal registry to determine which provider to call.

Generally, there are two ways of exposing your own performance counter data: a simple, function-based way and a more complex, but more powerful way of implementing a full performance counter. Both alternatives are described in the following sections.

Exposing performance counter data using a simple function

The simplest way to expose arbitrary numeric data is to write a function which will then be called whenever a consumer queries this counter. Currently, this type of performance counter can only be used to expose integer values. The expected signature of this function is:

```
std::int64_t some_performance_data(bool reset);
```

The argument `bool reset` (which is supplied by the runtime system when the function is invoked) specifies whether the counter value should be reset after evaluating the current value (if applicable).

For instance, here is such a function returning how often it was invoked:

```
// The atomic variable 'counter' ensures the thread safety of the counter.
boost::atomic<std::int64_t> counter(0);

std::int64_t some_performance_data(bool reset)
{
    std::int64_t result = ++counter;
    if (reset)
```

(continues on next page)

(continued from previous page)

```
        counter = 0;
    return result;
}
```

This example function exposes a linearly-increasing value as our performance data. The value is incremented on each invocation, i.e., each time a consumer requests the counter data of this performance counter.

The next step in exposing this counter to the runtime system is to register the function as a new raw counter type using the *HPX* API function `hpx::performance_counters::install_counter_type`. A counter type represents certain common characteristics of counters, like their counter type name and any associated description information. The following snippet shows an example of how to register the function `some_performance_data`, which is shown above, for a counter type named `"/test/data"`. This registration has to be executed before any consumer instantiates, and queries an instance of this counter type:

```
#include <hpx/include/performance_counters.hpp>

void register_counter_type()
{
    // Call the HPX API function to register the counter type.
    hpx::performance_counters::install_counter_type(
        "/test/data",                                      // counter type name
        &some_performance_data,                            // function providing counter␣
↪data
        "returns a linearly increasing counter value"    // description text (optional)
        ""                                                 // unit of measure (optional)
    );
}
```

Now it is possible to instantiate a new counter instance based on the naming scheme `"/test{locality#*/total}/data"` where `*` is a zero-based integer index identifying the *locality* for which the counter instance should be accessed. The function `hpx::performance_counters::install_counter_type` enables users to instantiate exactly one counter instance for each *locality*. Repeated requests to instantiate such a counter will return the same instance, i.e., the instance created for the first request.

If this counter needs to be accessed using the standard *HPX* command line options, the registration has to be performed during application startup, before `hpx_main` is executed. The best way to achieve this is to register an *HPX* startup function using the API function *hpx::register_startup_function* before calling `hpx::init` to initialize the runtime system:

```
int main(int argc, char* argv[])
{
    // By registering the counter type we make it available to any consumer
    // who creates and queries an instance of the type "/test/data".
    //
    // This registration should be performed during startup. The
    // function 'register_counter_type' should be executed as an HPX thread right
    // before hpx_main is executed.
    hpx::register_startup_function(&register_counter_type);

    // Initialize and run HPX.
    return hpx::init(argc, argv);
}
```

Please see the code in `simplest_performance_counter.cpp` for a full example demonstrating this functionality.

Implementing a full performance counter

Sometimes, the simple way of exposing a single value as a performance counter is not sufficient. For that reason, *HPX* provides a means of implementing full performance counters which support:

- Retrieving the descriptive information about the performance counter
- Retrieving the current counter value
- Resetting the performance counter (value)
- Starting the performance counter
- Stopping the performance counter
- Setting the (initial) value of the performance counter

Every full performance counter will implement a predefined interface:

}    // namespace hpx::performance_counters

#include <hpx/config/warnings_suffix.hpp>
```

In order to implement a full performance counter, you have to create an *HPX* component exposing this interface. To simplify this task, *HPX* provides a ready-made base class which handles all the boiler plate of creating a component for you. The remainder of this section will explain the process of creating a full performance counter based on the Sine example, which you can find in the directory `examples/performance_counters/sine/`.

The base class is defined in the header file `base_performance_counter.cpp` as:

```
//  Copyright (c) 2007-2026 Hartmut Kaiser
//
//  SPDX-License-Identifier: BSL-1.0
//  Distributed under the Boost Software License, Version 1.0. (See accompanying
//  file LICENSE_1_0.txt or copy at http://www.boost.org/LICENSE_1_0.txt)

#pragma once

#include <hpx/config.hpp>
#include <hpx/modules/actions_base.hpp>
#include <hpx/modules/components_base.hpp>
#include <hpx/modules/runtime_local.hpp>

#include <hpx/performance_counters/counters.hpp>
#include <hpx/performance_counters/server/base_performance_counter.hpp>

#if defined(DOXYGEN)
///////////////////////////////////////////////////////////////////////////////
//[performance_counter_base_class
namespace hpx::performance_counters {

    template <typename Derived>
    class base_performance_counter;
}    // namespace hpx::performance_counters
//]
#endif

///////////////////////////////////////////////////////////////////////////////
namespace hpx::performance_counters {

    HPX_CXX_EXPORT template <typename Derived>
    class base_performance_counter
      : public hpx::performance_counters::server::base_performance_counter
      , public hpx::components::component_base<Derived>
    {
    private:
        using base_type = hpx::components::component_base<Derived>;

    public:
        using type_holder = Derived;
        using base_type_holder =
            hpx::performance_counters::server::base_performance_counter;

        // NOLINTBEGIN(bugprone-crtp-constructor-accessibility)
        base_performance_counter() = default;

        explicit base_performance_counter(
            hpx::performance_counters::counter_info const& info)
          : base_type_holder(info)
        {
        }
```

(continues on next page)

(continued from previous page)

```
        // NOLINTEND(bugprone-crtp-constructor-accessibility)

        // Disambiguate finalize() which is implemented in both base classes
        void finalize()
        {
            base_type_holder::finalize();
            base_type::finalize();
        }

        hpx::naming::address get_current_address() const
        {
            return hpx::naming::address(
                hpx::naming::get_gid_from_locality_id(hpx::get_locality_id()),
                hpx::components::get_component_type<Derived>(),
                const_cast<Derived*>(static_cast<Derived const*>(this)));
        }
    };
}    // namespace hpx::performance_counters
```

The single template parameter is expected to receive the type of the derived class implementing the performance counter. In the Sine example this looks like:

```
//  Copyright (c) 2007-2012 Hartmut Kaiser
//
//  SPDX-License-Identifier: BSL-1.0
//  Distributed under the Boost Software License, Version 1.0. (See accompanying
//  file LICENSE_1_0.txt or copy at http://www.boost.org/LICENSE_1_0.txt)

#pragma once

#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/lcos_local.hpp>
#include <hpx/include/performance_counters.hpp>
#include <hpx/include/util.hpp>

#include <cstdint>

namespace performance_counters { namespace sine { namespace server {
    ///////////////////////////////////////////////////////////////////////////
    //[sine_counter_definition
    class sine_counter
      : public hpx::performance_counters::base_performance_counter<sine_counter>
    //]
    {
    public:
        sine_counter()
          : current_value_(0)
          , evaluated_at_(0)
        {
        }
```

(continues on next page)

(continued from previous page)

```
        explicit sine_counter(
            hpx::performance_counters::counter_info const& info);

        /// This function will be called in order to query the current value of
        /// this performance counter
        hpx::performance_counters::counter_value get_counter_value(bool reset);

        /// The functions below will be called to start and stop collecting
        /// counter values from this counter.
        bool start();
        bool stop();

        /// finalize() will be called just before the instance gets destructed
        void finalize();

    protected:
        bool evaluate();

    private:
        typedef hpx::spinlock mutex_type;

        mutable mutex_type mtx_;
        double current_value_;
        std::uint64_t evaluated_at_;

        hpx::util::interval_timer timer_;
    };
}}}    // namespace performance_counters::sine::server
#endif
```

i.e., the type `sine_counter` is derived from the base class passing the type as a template argument (please see `simplest_performance_counter.cpp` for the full source code of the counter definition). For more information about this technique (called Curiously Recurring Template Pattern - CRTP), please see for instance the corresponding Wikipedia article[182]. This base class itself is derived from the `performance_counter` interface described above.

Additionally, a full performance counter implementation not only exposes the actual value but also provides information about:

- The point in time a particular value was retrieved.
- A (sequential) invocation count.
- The actual counter value.
- An optional scaling coefficient.
- Information about the counter status.

[182] http://en.wikipedia.org/wiki/Curiously_recurring_template_pattern

Existing *HPX* performance counters

The *HPX* runtime system exposes a wide variety of predefined performance counters. These counters expose critical information about different modules of the runtime system. They can help determine system bottlenecks and fine-tune system and application performance.

Table 2.29: AGAS performance counter /agas/count/<agas_service>

Counter type	/agas/count/<agas_service> where <agas_service> is one of the following: *primary namespace services*: route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, allocate, begin_migration, end_migration *component namespace services*: bind_prefix, bind_name, resolve_id, unbind_name, iterate_types, get_component_typename, num_localities_type *locality namespace services*: free, localities, num_localities, num_threads, resolve_locality, resolved_localities *symbol namespace services*: bind, resolve, unbind, iterate_names, on_symbol_namespace_event
Counter instance formatting	<agas_instance>/total where <agas_instance> is the name of the *AGAS* service to query. Currently, this value will be locality#0 where 0 is the root *locality* (the id of the locality hosting the *AGAS* service). The value for * can be any *locality* id for the following <agas_service>: route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, bin, resolve, unbind, and iterate_names (only the primary and symbol *AGAS* service components live on all localities, whereas all other *AGAS* services are available on locality#0 only).
Description	Returns the total number of invocations of the specified *AGAS* service since its creation.

Table 2.30: AGAS performance counter /agas/<agas_service_category>/count

Counter type	/agas/<agas_service_category>/count where <agas_service_category> is one of the following: primary, locality, component or symbol
Counter instance formatting	<agas_instance>/total where <agas_instance> is the name of the *AGAS* service to query. Currently, this value will be locality#0 where 0 is the root *locality* (the id of the *locality* hosting the *AGAS* service). Except for <agas_service_category>, primary or symbol for which the value for * can be any *locality* id (only the primary and symbol *AGAS* service components live on all localities, whereas all other *AGAS* services are available on locality#0 only).
Description	Returns the overall total number of invocations of all *AGAS* services provided by the given *AGAS* service category since its creation.

Table 2.31: AGAS performance counter /agas/<agas_service_category>/count

Counter type	/agas/<agas_service_category>/count where <agas_service_category> is one of the following: primary, locality, component or symbol
Counter instance formatting	<agas_instance>/total where <agas_instance> is the name of the *AGAS* service to query. Currently, this value will be locality#0 where 0 is the root *locality* (the id of the *locality* hosting the *AGAS* service). Except for <agas_service_category>, primary or symbol for which the value for * can be any *locality* id (only the primary and symbol *AGAS* service components live on all localities, whereas all other *AGAS* services are available on locality#0 only).
Description	Returns the overall total number of invocations of all *AGAS* services provided by the given *AGAS* service category since its creation.

Table 2.32: AGAS performance counter agas/time/<agas_service>

Counter type	agas/time/<agas_service> where <agas_service> is one of the following: *primary namespace services*: route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, allocate begin_migration, end_migration *component namespace services*: bind_prefix, bind_name, resolve_id, unbind_name, iterate_types, get_component_typename, num_localities_type *locality namespace services*: free, localities, num_localities, num_threads, resolve_locality, resolved_localities *symbol namespace services*: bind, resolve, unbind, iterate_names, on_symbol_namespace_event
Counter instance formatting	<agas_instance>/total where <agas_instance> is the name of the *AGAS* service to query. Currently, this value will be locality#0 where 0 is the root *locality* (the id of the *locality* hosting the *AGAS* service). The value for * can be any *locality* id for the following <agas_service>: route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, bin, resolve, unbind, and iterate_names (only the primary and symbol *AGAS* service components live on all localities, whereas all other *AGAS* services are available on locality#0 only).
Description	Returns the overall execution time of the specified *AGAS* service since its creation (in nanoseconds).

Table 2.33: AGAS performance counter */agas/<agas_service_category>/time*`

Counter type	`/agas/<agas_service_category>/time` where `<agas_service_category>` is one of the following: `primary`, `locality`, `component` or `symbol`
Counter instance formatting	`<agas_instance>/total` where `<agas_instance>` is the name of the *AGAS* service to query. Currently, this value will be `locality#0` where `0` is the root *locality* (the id of the *locality* hosting the *AGAS* service). Except for `<agas_service_category` `primary` or `symbol` for which the value for * can be any *locality* id (only the primary and symbol *AGAS* service components live on all localities, whereas all other *AGAS* services are available on `locality#0` only).
Description	Returns the overall execution time of all *AGAS* services provided by the given *AGAS* service category since its creation (in nanoseconds).

Table 2.34: AGAS performance counter `/agas/count/entries`

Counter type	`/agas/count/entries`
Counter instance formatting	`locality#*/total` where * is the *locality* id of the *locality* the *AGAS* cache should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of cache entries resident in the *AGAS* cache of the specified *locality* (see `<cache_statistics>`).

Table 2.35: AGAS performance counter `/agas/count/<cache_statistics>`

Counter type	`/agas/count/<cache_statistics>` where `<cache_statistics>` is one of the following: `cache/evictions`, `cache/hits`, `cache/insertions`, `cache/misses`
Counter instance formatting	`locality#*/total` where * is the *locality* id of the *locality* the *AGAS* cache should be queried. The *locality* id is a (zero based) number identifying the *locality*
Description	Returns the number of cache events (evictions, hits, inserts, and misses) in the *AGAS* cache of the specified *locality* (see `<cache_statistics>`).

Table 2.36: AGAS performance counter `/agas/count/<full_cache_statistics>`

Counter type	`/agas/count/<full_cache_statistics>` where `<full_cache_statistics>` is one of the following: `cache/get_entry`, `cache/insert_entry`, `cache/update_entry`, `cache/erase_entry`
Counter instance formatting	`locality#*/total` where * is the *locality* id of the *locality* the *AGAS* cache should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of invocations of the specified cache API function of the *AGAS* cache.

Table 2.37: AGAS performance counter `/agas/time/<full_cache_statistics>`

Counter type	`/agas/time/<full_cache_statistics>` where `<full_cache_statistics>` is one of the following: `cache/get_entry`, `cache/insert_entry`, `cache/update_entry`, `cache/erase_entry`
Counter instance formatting	`locality#*/total` where `*` is the *locality* id of the *locality* the *AGAS* cache should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall time spent executing of the specified API function of the *AGAS* cache.

Table 2.38: Parcel layer performance counter `/data/count/<connection_type>/<operation>`

Counter type	`/data/count/<connection_type>/<operation>`
	where: `<operation>` is one of the following: `sent`, `received`
	`<connection_type>` is one of the following: `tcp`, `mpi`

Counter instance formatting	`locality#*/total` where `*` is the *locality* id of the *locality* the overall number of transmitted bytes should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number of raw (uncompressed) bytes sent or received (see `<operation>`, e.g. `sent` or `received`) for the specified `<connection_type>`. The performance counters are available only if the compile time constant `HPX_HAVE_PARCELPORT_COUNTERS` was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_COUNTERS`. The performance counters for the connection type `mpi` are available only if the compile time constant `HPX_HAVE_PARCELPORT_MPI` was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_MPI`. Please see *CMake options* for more details.

Table 2.39: Parcel layer performance counter /data/time/<connection_type>/<operation>

Counter type	/data/time/<connection_type>/<operation> where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the total transmission time should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the total time (in nanoseconds) between the start of each asynchronous transmission operation and the end of the corresponding operation for the specified <connection_type> the given *locality* (see <operation>, e.g. sent or received). The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.40: Parcel layer performance counter /serialize/count/<connection_type>/<operation>

Counter type	/serialize/count/<connection_type>/<operation> where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the overall number of transmitted bytes should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number of bytes transferred (see <operation>, e.g. sent or received possibly compressed) for the specified <connection_type> by the given *locality*. The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.
Description	If the configure-time option -DHPX_WITH_PARCELPORT_ACTION_COUNTERS=On was specified, this counter allows one to specify an optional action name as its parameter. In this case the counter will report the number of bytes transmitted for the given action only.

Table 2.41: Parcel layer performance counter /serialize/time/<connection_type>/<operation>

Counter type	/serialize/time/<connection_type>/<operation> where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the serialization time should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall time spent performing outgoing data serialization for the specified <connection_type> on the given *locality* (see <operation>, e.g. sent or received). The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.
Parameters	If the configure-time option -DHPX_WITH_PARCELPORT_ACTION_COUNTERS=On was specified, this counter allows one to specify an optional action name as its parameter. In this case the counter will report the serialization time for the given action only.

Table 2.42: Parcel layer performance counter /parcels/count/routed

Counter type	/parcels/count/routed
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the number of routed parcels should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number of routed (outbound) parcels transferred by the given *locality*. Routed parcels are those which cannot directly be delivered to its destination as the local *AGAS* is not able to resolve the destination address. In this case a parcel is sent to the *AGAS* service component which is responsible for creating the destination GID (and is responsible for resolving the destination address). This *AGAS* service component will deliver the parcel to its final target.
Parameters	If the configure-time option -DHPX_WITH_PARCELPORT_ACTION_COUNTERS=On was specified, this counter allows one to specify an optional action name as its parameter. In this case the counter will report the number of parcels for the given action only.

Table 2.43: Parcel layer performance counter `/parcels/count/<connection_type>/<operation>`

Counter type	`/parcels/count/<connection_type>/<operation>`
	where:
	`<operation>` is one of the following: `sent`, `received`
	`<connection_type>` is one of the following: `tcp`, `mpi`

Counter instance formatting	`locality#*/total` where `*` is the *locality* id of the *locality* the number of parcels should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number of parcels transferred using the specified `<connection_type>` by the given *locality* (see `operation>`, e.g. `sent` or `received`. The performance counters are available only if the compile time constant `HPX_HAVE_PARCELPORT_COUNTERS` was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_COUNTERS`. The performance counters for the connection type `mpi` are available only if the compile time constant `HPX_HAVE_PARCELPORT_MPI` was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_MPI`. Please see *CMake options* for more details.

Table 2.44: Parcel layer performance counter `/messages/count/<connection_type>/<operation>`

Counter type	`/messages/count/<connection_type>/<operation>` where:
	`<operation>` is one of the following: `sent`, `received`
	`<connection_type>` is one of the following: `tcp`, `mpi`

Counter instance formatting	`locality#*/total` where `*` is the *locality* id of the *locality* the number of messages should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number of messages[183] transferred using the specified `<connection_type>` by the given *locality* (see `<operation>`, e.g. `sent` or `received`) The performance counters are available only if the compile time constant `HPX_HAVE_PARCELPORT_COUNTERS` was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_COUNTERS`. The performance counters for the connection type `mpi` are available only if the compile time constant `HPX_HAVE_PARCELPORT_MPI` was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_MPI`. Please see *CMake options* for more details.

[183] A message can potentially consist of more than one *parcel*.

Table 2.45: Parcel layer performance counter /parcelport/count/<connection_type>/zero_copy_chunks/<operation>

Counter type	/parcelport/count/<connection_type>/zero_copy_chunks/<operation> where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the overall number of transmitted bytes should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number of zero-copy chunks sent or received (see <operation>, e.g. sent or received) for the specified <connection_type>. The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.46: Parcel layer performance counter /parcelport/count-max/<connection_type>/zero_copy_chunks/<operation>

Counter type	/parcelport/count-max/<connection_type>/zero_copy_chunks/<operation> where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the overall number of transmitted bytes should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the maximum number of zero-copy chunks sent or received per message (see <operation>, e.g. sent or received) for the specified <connection_type>. The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.47: Parcel layer performance counter /parcelport/size/<connection_type>/zero_copy_chunks/<operation>

Counter type	/parcelport/size/<connection_type>/zero_copy_chunks/<operation> where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the overall number of transmitted bytes should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall size of zero-copy chunks sent or received (see <operation>, e.g. sent or received) for the specified <connection_type>. The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.48: Parcel layer performance counter /parcelport/size-max/<connection_type>/zero_copy_chunks/<operation>

Counter type	/parcelport/size-max/<connection_type>/zero_copy_chunks/<operation> where: <operation> is one of the following: sent, received <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the overall number of transmitted bytes should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the maximum size of zero-copy chunks sent or received (see <operation>, e.g. sent or received) for the specified <connection_type>. The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.49: Parcel layer performance counter /parcelport/count/<connection_type>/<cache_statistics>

Counter type	/parcelport/count/<connection_type>/<cache_statistics> where: <cache_statistics> is one of the following: cache/insertions, cache/evictions, cache/hits, cache/misses, cache/reclaims <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the number of messages should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number cache events (evictions, hits, inserts, misses, and reclaims) for the connection cache of the given connection type on the given *locality* (see <cache_statistics, e.g. ache/insertions, cache/evictions, cache/hits, cache/misses or``cache/reclaims``. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.50: Parcel layer performance counter /parcelport/count/<connection_type>/cache-reservation-failures

Counter type	/parcelport/count/<connection_type>/cache-reservation-failures where <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the counter should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the cumulative number of times get_or_reserve() returned false because every connection slot in the connection cache was already checked out (pool saturation). This is distinct from ordinary cache misses, which occur whenever a new connection to a *locality* is first created and do not cause parcel deferral. A non-zero and growing value of this counter means that outgoing parcels are being silently queued until a connection is reclaimed; raising hpx.max_connections or hpx.max_connections_per_locality in the ini configuration will relieve the saturation. When pool exhaustion is detected, *HPX* also emits a warning-level log message (throttled to at most once every five seconds) of the form: parcelport connection cache exhausted: N/M connections in use, K deferred reservation(s) since last reset. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.51: Parcel layer performance counters /parcelport/count/<connection_type>/cache-connections and /parcelport/count/<connection_type>/cache-max-connections

Counter type	/parcelport/count/<connection_type>/cache-connections /parcelport/count/<connection_type>/cache-max-connections where <connection_type> is one of the following: tcp, mpi
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the counter should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	cache-connections returns the current number of connections tracked by the connection cache for the given connection type on the given *locality*. This includes both connections that are currently checked out and connections that are idle and available for reuse. cache-max-connections returns the configured upper limit on the total number of connections the cache is allowed to hold. This value is fixed at startup and corresponds to the hpx.max_connections ini key. Together these two counters give the pool utilisation ratio. If cache-connections is consistently equal to cache-max-connections and cache-reservation-failures is increasing, the connection pool is saturated and the limit should be raised. The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the *HPX* core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI. Please see *CMake options* for more details.

Table 2.52: Parcel layer performance counter /parcelqueue/length/<operation>

Counter type	/parcelqueue/length/<operation> where <operation> is one of the following: sent, receive
Counter instance formatting	locality#*/total where * is the *locality* id of the *locality* the *parcel* queue should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the current number of parcels stored in the *parcel* queue (see <operation> for which queue to query, e.g. sent or received).

Table 2.53: Thread manager performance counter /threads/count/cumulative

Counter type	/threads/count/cumulative
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the overall number of retired *HPX*-threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. **pool#* is defining the pool for which the current value of the** idle-loop counter should be queried for. **worker-thread#* is defining the worker thread for which the overall** number of retired *HPX*-threads should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the overall number of executed (retired) *HPX*-threads on the given *locality* since application start. If the instance name is total the counter returns the accumulated number of retired *HPX*-threads for all worker threads (cores) on that *locality*. If the instance name is worker-thread#* the counter will return the overall number of retired *HPX*-threads for all worker threads separately. This counter is available only if the configuration time constant HPX_WITH_THREAD_CUMULATIVE_COUNTS is set to ON (default: ON).

Table 2.54: Thread manager performance counter /threads/time/average

Counter type	/threads/time/average
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the average time spent executing one *HPX*-thread should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the average time spent executing one *HPX*-thread should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the average time spent executing one *HPX*-thread on the given *locality* since application start. If the instance name is total the counter returns the average time spent executing one *HPX*-thread for all worker threads (cores) on that *locality*. If the instance name is worker-thread#* the counter will return the average time spent executing one *HPX*-thread for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_THREAD_CUMULATIVE_COUNTS (default: ON) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure for this counter is nanosecond [ns].

Table 2.55: Thread manager performance counter `/threads/time/average-overhead`

Counter type	`/threads/time/average-overhead`
Counter instance formatting	`locality#*/total` or `locality#*/worker-thread#*` or `locality#*/pool#*/worker-thread#*` where: `locality#*` is defining the *locality* for which the average overhead spent executing one *HPX*-thread should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. `pool#*` is defining the pool for which the current value of the idle-loop counter should be queried for. `worker-thread#*` is defining the worker thread for which the average overhead spent executing one *HPX*-thread should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option `--hpx:threads`. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the average time spent on overhead while executing one *HPX*-thread on the given *locality* since application start. If the instance name is `total` the counter returns the average time spent on overhead while executing one *HPX*-thread for all worker threads (cores) on that *locality*. If the instance name is `worker-thread#*` the counter will return the average time spent on overhead executing one *HPX*-thread for all worker threads separately. This counter is available only if the configuration time constants `HPX_WITH_THREAD_CUMULATIVE_COUNTS` (default: `ON`) and `HPX_WITH_THREAD_IDLE_RATES` are set to `ON` (default: `OFF`). The unit of measure for this counter is nanosecond [ns].

Table 2.56: Thread manager performance counter `/threads/count/cumulative-phases`

Counter type	`/threads/count/cumulative-phases`
Counter instance formatting	`locality#*/total` or `locality#*/worker-thread#*` or `locality#*/pool#*/worker-thread#*` where: `locality#*` is defining the *locality* for which the overall number of executed *HPX*-thread phases (invocations) should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. `pool#*` is defining the pool for which the current value of the idle-loop counter should be queried for. `worker-thread#*` is defining the worker thread for which the overall number of executed *HPX*-thread phases (invocations) should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option `--hpx:threads`. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the overall number of executed *HPX*-thread phases (invocations) on the given *locality* since application start. If the instance name is `total` the counter returns the accumulated number of executed *HPX*-thread phases (invocations) for all worker threads (cores) on that *locality*. If the instance name is `worker-thread#*` the counter will return the overall number of executed *HPX*-thread phases for all worker threads separately. This counter is available only if the configuration time constant `HPX_WITH_THREAD_CUMULATIVE_COUNTS` is set to `ON` (default: `ON`). The unit of measure for this counter is nanosecond [ns].

Table 2.57: Thread manager performance counter /threads/time/average-phase

Counter type	/threads/time/average-phase
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the average time spent executing one *HPX*-thread phase (invocation) should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the average time executing one *HPX*-thread phase (invocation) should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option --hpx:threads. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the average time spent executing one *HPX*-thread phase (invocation) on the given *locality* since application start. If the instance name is total the counter returns the average time spent executing one *HPX*-thread phase (invocation) for all worker threads (cores) on that *locality*. If the instance name is worker-thread#* the counter will return the average time spent executing one *HPX*-thread phase for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_THREAD_CUMULATIVE_COUNTS (default: ON) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure for this counter is nanosecond [ns].

Table 2.58: Thread manager performance counter `/threads/time/average-phase-overhead`

Counter type	`/threads/time/average-phase-overhead`
Counter instance formatting	`locality#*/total` or `locality#*/worker-thread#*` or `locality#*/pool#*/worker-thread#*` where: `locality#*` is defining the *locality* for which the average time overhead executing one *HPX*-thread phase (invocation) should be queried for. The *locality* id (given by the `*`) is a (zero based) number identifying the *locality*. `pool#*` is defining the pool for which the current value of the idle-loop counter should be queried for. `worker-thread#*` is defining the worker thread for which the average overhead executing one *HPX*-thread phase (invocation) should be queried for. The worker thread number (given by the `*`) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option `--hpx:threads`. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the average time spent on overhead executing one *HPX*-thread phase (invocation) on the given *locality* since application start. If the instance name is `total` the counter returns the average time spent on overhead while executing one *HPX*-thread phase (invocation) for all worker threads (cores) on that *locality*. If the instance name is `worker-thread#*` the counter will return the average time spent on overhead executing one *HPX*-thread phase for all worker threads separately. This counter is available only if the configuration time constants `HPX_WITH_THREAD_CUMULATIVE_COUNTS` (default: `ON`) and `HPX_WITH_THREAD_IDLE_RATES` are set to `ON` (default: `OFF`). The unit of measure for this counter is nanosecond [ns].

Table 2.59: Thread manager performance counter `/threads/time/overall`

Counter type	`/threads/time/overall`
Counter instance formatting	`locality#*/total` or `locality#*/worker-thread#*` or `locality#*/pool#*/worker-thread#*` where: `locality#*` is defining the *locality* for which the overall time spent running the scheduler should be queried for. The *locality* id (given by the `*`) is a (zero based) number identifying the *locality*. `pool#*` is defining the pool for which the current value of the idle-loop counter should be queried for. `worker-thread#*` is defining the worker thread for which the overall time spent running the scheduler should be queried for. The worker thread number (given by the `*`) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option `--hpx:threads`. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the overall time spent running the scheduler on the given *locality* since application start. If the instance name is `total` the counter returns the overall time spent running the scheduler for all worker threads (cores) on that *locality*. If the instance name is `worker-thread#*` the counter will return the overall time spent running the scheduler for all worker threads separately. This counter is available only if the configuration time constant `HPX_WITH_THREAD_IDLE_RATES` is set to `ON` (default: `OFF`). The unit of measure for this counter is nanosecond [ns].

Table 2.60: Thread manager performance counter /threads/time/cumulative

Counter type	/threads/time/cumulative
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the overall time spent executing all *HPX*-threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the overall time spent executing all *HPX*-threads should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the overall time spent executing all *HPX*-threads on the given *locality* since application start. If the instance name is total the counter returns the overall time spent executing all *HPX*-threads for all worker threads (cores) on that *locality*. If the instance name is worker-thread#* the counter will return the overall time spent executing all *HPX*-threads for all worker threads separately. This counter is available only if the configuration time constants HPX_THREAD_MAINTAIN_CUMULATIVE_COUNTS (default: ON) and HPX_THREAD_MAINTAIN_IDLE_RATES are set to ON (default: OFF).

Table 2.61: Thread manager performance counter /threads/time/cumulative-overheads

Counter type	/threads/time/cumulative-overheads
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the overall overhead time incurred by executing all *HPX*-threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the the overall overhead time incurred by executing all *HPX*-threads should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the overall overhead time incurred executing all *HPX*-threads on the given *locality* since application start. If the instance name is total the counter returns the overall overhead time incurred executing all *HPX*-threads for all worker threads (cores) on that *locality*. If the instance name is worker-thread#* the counter will return the overall overhead time incurred executing all *HPX*-threads for all worker threads separately. This counter is available only if the configuration time constants HPX_THREAD_MAINTAIN_CUMULATIVE_COUNTS (default: ON) and HPX_THREAD_MAINTAIN_IDLE_RATES are set to ON (default: OFF). The unit of measure for this counter is nanosecond [ns].

Table 2.62: Thread manager performance counter threads/count/instantaneous/<thread-state>

Counter type	threads/count/instantaneous/<thread-state> where: <thread-state> is one of the following: all, active, pending, suspended, terminated, staged
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the current number of threads with the given state should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the current number of threads with the given state should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool. The staged thread state refers to registered tasks before they are converted to thread objects.
Description	Returns the current number of *HPX*-threads having the given thread state on the given *locality*. If the instance name is total the counter returns the current number of *HPX*-threads of the given state for all worker threads (cores) on that *locality*. If the instance name is worker-thread#* the counter will return the current number of *HPX*-threads in the given state for all worker threads separately.

Table 2.63: Thread manager performance counter threads/wait-time/<thread-state>

Counter type	threads/wait-time/<thread-state> where: <thread-state> is one of the following: pending staged
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the average wait time of *HPX*-threads (pending) or thread descriptions (staged) with the given state should be queried for. The *locality* id (given by * is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the average wait time for the given state should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool. The staged thread state refers to the wait time of registered tasks before they are converted into thread objects, while the pending thread state refers to the wait time of threads in any of the scheduling queues.
Description	Returns the average wait time of *HPX*-threads (if the thread state is pending or of task descriptions (if the thread state is staged on the given *locality* since application start. If the instance name is total the counter returns the wait time of *HPX*-threads of the given state for all worker threads (cores) on that *locality*. If the instance name is worker-thread#* the counter will return the wait time of *HPX*-threads in the given state for all worker threads separately. These counters are available only if the compile time constant HPX_WITH_THREAD_QUEUE_WAITTIME was defined while compiling the *HPX* core library (default: OFF). The unit of measure for this counter is nanosecond [ns].

Table 2.64: Thread manager performance counter /threads/idle-rate

Counter type	/threads/idle-rate
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the average idle rate of all (or one) worker threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality* pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the averaged idle rate should be queried for. The worker thread number (given by the * is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the average idle rate for the given worker thread(s) on the given *locality*. The idle rate is defined as the ratio of the time spent on scheduling and management tasks and the overall time spent executing work since the application started. This counter is available only if the configuration time constant HPX_WITH_THREAD_IDLE_RATES is set to ON (default: OFF).

Table 2.65: Thread manager performance counter /threads/creation-idle-rate

Counter type	/threads/creation-idle-rate
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the average creation idle rate of all (or one) worker threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the averaged idle rate should be queried for. The worker thread number (given by the * is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the average idle rate for the given worker thread(s) on the given *locality* which is caused by creating new threads. The creation idle rate is defined as the ratio of the time spent on creating new threads and the overall time spent executing work since the application started. This counter is available only if the configuration time constants HPX_WITH_THREAD_IDLE_RATES (default: OFF) and HPX_WITH_THREAD_CREATION_AND_CLEANUP_RATES are set to ON.

Table 2.66: Thread manager performance counter /threads/cleanup-idle-rate

Counter type	/threads/cleanup-idle-rate
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the average cleanup idle rate of all (or one) worker threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the averaged cleanup idle rate should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the average idle rate for the given worker thread(s) on the given *locality* which is caused by cleaning up terminated threads. The cleanup idle rate is defined as the ratio of the time spent on cleaning up terminated thread objects and the overall time spent executing work since the application started. This counter is available only if the configuration time constants HPX_WITH_THREAD_IDLE_RATES (default: OFF) and HPX_WITH_THREAD_CREATION_AND_CLEANUP_RATES are set to ON.

Table 2.67: Thread manager performance counter /threadqueue/length

Counter type	/threadqueue/length
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the current length of all thread queues in the scheduler for all (or one) worker threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the current length of all thread queues in the scheduler should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the overall length of all queues for the given worker thread(s) on the given *locality*.

Table 2.68: Thread manager performance counter `/threads/count/stack-unbinds`

Counter type	`/threads/count/stack-unbinds`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the unbind (madvise) operations should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the total number of *HPX*-thread unbind (madvise) operations performed for the referenced *locality*. Note that this counter is not available on Windows based platforms.

Table 2.69: Thread manager performance counter `/threads/count/stack-recycles`

Counter type	`/threads/count/stack-recycles`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the recycling operations should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the total number of *HPX*-thread recycling operations performed.

Table 2.70: Thread manager performance counter `/threads/count/stolen-from-pending`

Counter type	`/threads/count/stolen-from-pending`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of 'stole' threads should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the total number of *HPX*-threads 'stolen' from the pending thread queue by a neighboring thread worker thread (these threads are executed by a different worker thread than they were initially scheduled on). This counter is available only if the configuration time constant `HPX_WITH_THREAD_STEALING_COUNTS` is set to `ON` (default: `ON`).

Table 2.71: Thread manager performance counter `/threads/count/pending-misses`

Counter type	`/threads/count/pending-misses`
Counter instance formatting	`locality#*/total` or `locality#*/worker-thread#*` or `locality#*/pool#*/worker-thread#*` where: `locality#*` is defining the *locality* for which the number of pending queue misses of all (or one) worker threads should be queried for. The *locality* id (given by the `*`) is a (zero based) number identifying the *locality* `pool#*` is defining the pool for which the current value of the idle-loop counter should be queried for. `worker-thread#*` is defining the worker thread for which the number of pending queue misses should be queried for. The worker thread number (given by the `*`) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option `--hpx:threads`. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the total number of times that the referenced worker-thread on the referenced *locality* failed to find pending *HPX*-threads in its associated queue. This counter is available only if the configuration time constant `HPX_WITH_THREAD_STEALING_COUNTS` is set to `ON` (default: `ON`).

Table 2.72: Thread manager performance counter `/threads/count/pending-accesses`

Counter type	`/threads/count/pending-accesses`
Counter instance formatting	`locality#*/total` or `locality#*/worker-thread#*` or `locality#*/pool#*/worker-thread#*` where: `locality#*` is defining the *locality* for which the number of pending queue accesses of all (or one) worker threads should be queried for. The *locality* id (given by the `*`) is a (zero based) number identifying the *locality* `pool#*` is defining the pool for which the current value of the idle-loop counter should be queried for. `worker-thread#*` is defining the worker thread for which the number of pending queue accesses should be queried for. The worker thread number (given by the `*`) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option `--hpx:threads`. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the total number of times that the referenced worker-thread on the referenced *locality* looked for pending *HPX*-threads in its associated queue. This counter is available only if the configuration time constant `HPX_WITH_THREAD_STEALING_COUNTS` is set to `ON` (default: `ON`).

Table 2.73: Thread manager performance counter /threads/count/stolen-from-staged

Counter type	/threads/count/stolen-from-staged
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the number of *HPX*-threads stolen from the staged queue of all (or one) worker threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the number of *HPX*-threads stolen from the staged queue should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the total number of *HPX*-threads 'stolen' from the staged thread queue by a neighboring worker thread (these threads are executed by a different worker thread than they were initially scheduled on). This counter is available only if the configuration time constant HPX_WITH_THREAD_STEALING_COUNTS is set to ON (default: ON).

Table 2.74: Thread manager performance counter /threads/count/stolen-to-pending

Counter type	/threads/count/stolen-to-pending
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the number of *HPX*-threads stolen to the pending queue of all (or one) worker threads should be queried for. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the number of *HPX*-threads stolen to the pending queue should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the total number of *HPX*-threads 'stolen' to the pending thread queue of the worker thread (these threads are executed by a different worker thread than they were initially scheduled on). This counter is available only if the configuration time constant HPX_WITH_THREAD_STEALING_COUNTS is set to ON (default: ON).

Table 2.75: Thread manager performance counter /threads/count/stolen-to-staged

Counter type	/threads/count/stolen-to-staged
Counter instance formatting	locality#*/total or locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the number of *HPX*-threads stolen to the staged queue of all (or one) worker threads should be queried for. The *locality* id (given by *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the number of *HPX*-threads stolen to the staged queue should be queried for. The worker thread number (given by the *) is a (zero based) worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the total number of *HPX*-threads 'stolen' to the staged thread queue of a neighboring worker thread (these threads are executed by a different worker thread than they were initially scheduled on). This counter is available only if the configuration time constant HPX_WITH_THREAD_STEALING_COUNTS is set to ON (default: ON).

Table 2.76: Thread manager performance counter /threads/count/objects

Counter type	/threads/count/objects
Counter instance formatting	locality#*/total or locality#*/allocator#* where: locality#* is defining the *locality* for which the current (cumulative) number of all created *HPX*-thread objects should be queried for. The *locality* id (given by *) is a (zero based) number identifying the *locality*. allocator#* is defining the number of the allocator instance using which the threads have been created. *HPX* uses a varying number of allocators to create (and recycle) *HPX*-thread objects, most likely these counters are of use for debugging purposes only. The allocator id (given by *) is a (zero based) number identifying the allocator to query.
Description	Returns the total number of *HPX*-thread objects created. Note that thread objects are reused to improve system performance, thus this number does not reflect the number of actually executed (retired) *HPX*-threads.

Table 2.77: Thread manager performance counter `/scheduler/utilization/instantaneous`

Counter type	`/scheduler/utilization/instantaneous`
Counter instance formatting	`locality#*/total` where: `locality#*` is defining the *locality* for which the current (instantaneous) scheduler utilization queried for. The *locality* id (given by *) is a (zero based) number identifying the *locality*.
Description	**Returns the total (instantaneous) scheduler utilization. This is the** current percentage of scheduler threads executing *HPX* threads.
Parameters	Percent

Table 2.78: Thread manager performance counter `/threads/idle-loop-count/instantaneous`

Counter type	`/threads/idle-loop-count/instantaneous`
Counter instance formatting	`locality#*/worker-thread#*` or `locality#*/pool#*/worker-thread#*` where: `locality#*` is defining the *locality* for which the current current accumulated value of all idle-loop counters of all worker threads should be queried. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. `pool#*` is defining the pool for which the current value of the idle-loop counter should be queried for. `worker-thread#*` is defining the worker thread for which the current value of the idle-loop counter should be queried for. The worker thread number (given by the *) is a (zero based) worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option `--hpx:threads`. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the current (instantaneous) idle-loop count for the given *HPX*- worker thread or the accumulated value for all worker threads.

Table 2.79: Thread manager performance counter /threads/busy-loop-count/instantaneous

Counter type	/threads/busy-loop-count/instantaneous
Counter instance formatting	locality#*/worker-thread#* or locality#*/pool#*/worker-thread#* where: locality#* is defining the *locality* for which the current current accumulated value of all busy-loop counters of all worker threads should be queried. The *locality* id (given by the *) is a (zero based) number identifying the *locality*. pool#* is defining the pool for which the current value of the idle-loop counter should be queried for. worker-thread#* is defining the worker thread for which the current value of the busy-loop counter should be queried for. The worker thread number (given by the *) is a (zero based) worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*. If no pool-name is specified the counter refers to the 'default' pool.
Description	Returns the current (instantaneous) busy-loop count for the given *HPX*- worker thread or the accumulated value for all worker threads.

Table 2.80: Thread manager performance counter /threads/time/background-work-duration

Counter type	/threads/time/background-work-duration
Counter instance formatting	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the locality for which the overall time spent performing background work should be queried for. The locality id (given by *) is a (zero based) number identifying the locality. worker-thread#* is defining the worker thread for which the overall time spent performing background work should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*.
Description	Returns the overall time spent performing background work on the given locality since application start. If the instance name is total the counter returns the overall time spent performing background work for all worker threads (cores) on that locality. If the instance name is worker-thread#* the counter will return the overall time spent performing background work for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_BACKGROUND_THREAD_COUNTERS (default: OFF) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure for this counter is nanosecond [ns].

Table 2.81: Thread manager performance counter /threads/background-overhead

Counter type	/threads/background-overhead
Counter instance formatting	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the locality for which the background overhead should be queried for. The locality id (given by *) is a (zero based) number identifying the locality. worker-thread#* is defining the worker thread for which the background overhead should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option --hpx:threads.
Description	Returns the background overhead on the given locality since application start. If the instance name is total the counter returns the background overhead for all worker threads (cores) on that locality. If the instance name is worker-thread#* the counter will return background overhead for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_BACKGROUND_THREAD_COUNTERS (default: OFF) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure displayed for this counter is 0.1%.

Table 2.82: Thread manager performance counter /threads/time/background-send-duration

Counter type	/threads/time/background-send-duration
Counter instance formatting	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the locality for which the overall time spent performing background work related to sending parcels should be queried for. The locality id (given by *) is a (zero based) number identifying the locality. worker-thread#* is defining the worker thread for which the overall time spent performing background work related to sending parcels should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option --hpx:threads.
Description	Returns the overall time spent performing background work related to sending parcels on the given locality since application start. If the instance name is total the counter returns the overall time spent performing background work for all worker threads (cores) on that locality. If the instance name is worker-thread#* the counter will return the overall time spent performing background work for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_BACKGROUND_THREAD_COUNTERS (default: OFF) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure for this counter is nanosecond [ns]. This counter will currently return meaningful values for the MPI parcelport only.

Table 2.83: Thread manager performance counter /threads/background-send-overhead

Counter type	/threads/background-send-overhead
Counter instance formatting	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the locality for which the background overhead related to sending parcels should be queried for. The locality id (given by *) is a (zero based) number identifying the locality. worker-thread#* is defining the worker thread for which the background overhead related to sending parcels should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*.
Description	Returns the background overhead related to sending parcels on the given locality since application start. If the instance name is total the counter returns the background overhead for all worker threads (cores) on that locality. If the instance name is worker-thread#* the counter will return background overhead for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_BACKGROUND_THREAD_COUNTERS (default: OFF) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure displayed for this counter is 0.1%. This counter will currently return meaningful values for the MPI parcelport only.

Table 2.84: Thread manager performance counter /threads/time/background-receive-duration

Counter type	/threads/time/background-receive-duration
Counter instance formatting	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the locality for which the overall time spent performing background work related to receiving parcels should be queried for. The locality id (given by *) is a (zero based) number identifying the locality. worker-thread#* is defining the worker thread for which the overall time spent performing background work related to receiving parcels should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*.
Description	Returns the overall time spent performing background work related to receiving parcels on the given locality since application start. If the instance name is total the counter returns the overall time spent performing background work for all worker threads (cores) on that locality. If the instance name is worker-thread#* the counter will return the overall time spent performing background work for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_BACKGROUND_THREAD_COUNTERS (default: OFF) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure for this counter is nanosecond [ns]. This counter will currently return meaningful values for the MPI parcelport only.

Table 2.85: Thread manager performance counter /threads/background-receive-overhead

Counter type	/threads/background-receive-overhead
Counter instance formatting	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the locality for which the background overhead related to receiving should be queried for. The locality id (given by *) is a (zero based) number identifying the locality. worker-thread#* is defining the worker thread for which the background overhead related to receiving parcels should be queried for. The worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*.
Description	Returns the background overhead related to receiving parcels on the given locality since application start. If the instance name is total the counter returns the background overhead for all worker threads (cores) on that locality. If the instance name is worker-thread#* the counter will return background overhead for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_BACKGROUND_THREAD_COUNTERS (default: OFF) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure displayed for this counter is 0.1%. This counter will currently return meaningful values for the MPI parcelport only.

Table 2.86: General performance counter /runtime/count/component

Counter type	/runtime/count/component
Counter instance formatting	locality#*/total where: * is the *locality* id of the *locality* the number of components should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall number of currently active components of the specified type on the given *locality*.
Parameters	The type of the component. This is the string which has been used while registering the component with *HPX*, e.g. which has been passed as the second parameter to the macro *HPX_REGISTER_COMPONENT*.

Table 2.87: General performance counter /runtime/count/action-invocation

Counter type	/runtime/count/action-invocation
Counter instance formatting	locality#*/total where: * is the *locality* id of the locality the number of action invocations should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall (local) invocation count of the specified action type on the given *locality*.
Parameters	The action type. This is the string which has been used while registering the action with *HPX*, e.g. which has been passed as the second parameter to the macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID*.

Table 2.88: General performance counter `/runtime/count/remote-action-invocation`

Counter type	`/runtime/count/remote-action-invocation`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of action invocations should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall (remote) invocation count of the specified action type on the given *locality*.
Parameters	The action type. This is the string which has been used while registering the action with *HPX*, e.g. which has been passed as the second parameter to the macro *`HPX_REGISTER_ACTION`* or *`HPX_REGISTER_ACTION_ID`*.

Table 2.89: General performance counter `/runtime/uptime`

Counter type	`/runtime/uptime`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the system uptime should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the overall time since application start on the given *locality* in nanoseconds.

Table 2.90: General performance counter `/runtime/memory/virtual`

Counter type	`/runtime/memory/virtual`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the allocated virtual memory should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the amount of virtual memory currently allocated by the referenced *locality* (in bytes).

Table 2.91: General performance counter `/runtime/memory/resident`

Counter type	`/runtime/memory/resident`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the allocated resident memory should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the amount of resident memory currently allocated by the referenced *locality* (in bytes).

Table 2.92: General performance counter `/runtime/memory/total`

Counter type	`/runtime/memory/total`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the total available memory should be queried. The *locality* id is a (zero based) number identifying the *locality*. Note: only supported in Linux.
Description	**Returns the total available memory for use by the referenced** *locality* (in bytes). This counter is available on Linux and Windows systems only.

Table 2.93: General performance counter `/runtime/io/read_bytes_issued`

Counter type	`/runtime/io/read_bytes_issued`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of bytes read should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of bytes read by the process (aggregate of count arguments passed to read() call or its analogues). This performance counter is available only on systems which expose the related data through the /proc file system.

Table 2.94: General performance counter `/runtime/io/write_bytes_issued`

Counter type	`/runtime/io/write_bytes_issued`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of bytes written should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of bytes written by the process (aggregate of count arguments passed to write() call or its analogues). This performance counter is available only on systems which expose the related data through the /proc file system.

Table 2.95: General performance counter `/runtime/io/read_syscalls`

Counter type	`/runtime/io/read_syscalls`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of system calls should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of system calls that perform I/O reads. This performance counter is available only on systems which expose the related data through the /proc file system.

Table 2.96: General performance counter /runtime/io/write_syscalls

Counter type	`/runtime/io/write_syscalls`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of system calls should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of system calls that perform I/O writes. This performance counter is available only on systems which expose the related data through the /proc file system.

Table 2.97: General performance counter /runtime/io/read_bytes_transferred

Counter type	`/runtime/io/read_bytes_transferred`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of bytes transferred should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of bytes retrieved from storage by I/O operations. This performance counter is available only on systems which expose the related data through the /proc file system.

Table 2.98: General performance counter /runtime/io/write_bytes_transferred

Counter type	`/runtime/io/write_bytes_transferred`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of bytes transferred should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of bytes retrieved from storage by I/O operations. This performance counter is available only on systems which expose the related data through the /proc file system.

Table 2.99: General performance counter /runtime/io/write_bytes_cancelled

Counter type	`/runtime/io/write_bytes_cancelled`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of bytes not being transferred should be queried. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of bytes accounted by write_bytes_transferred that has not been ultimately stored due to truncation or deletion. This performance counter is available only on systems which expose the related data through the /proc file system.

Table 2.100: Performance counter /papi/<papi_event>

Counter type	/papi/<papi_event> where: <papi_event> is the name of the PAPI event to expose as a performance counter (such as PAPI_SR_INS). Note that the list of available PAPI events changes depending on the used architecture. For a full list of available PAPI events and their (short) description use the --hpx:list-counters and --hpx:papi-event-info=all command line options.
Counter instance formatting	locality#*/total or locality#*/worker-thread#* where: locality#* is defining the *locality* for which the current current accumulated value of all busy-loop counters of all worker threads should be queried. The *locality* id (given by *) is a (zero based) number identifying the *locality*. worker-thread#* is defining the worker thread for which the current value of the busy-loop counter should be queried for. The worker thread number (given by the *) is a (zero based) worker thread number (given by the *) is a (zero based) number identifying the worker thread. The number of available worker threads is usually specified on the command line for the application using the option *--hpx:threads*.
Description	Returns the current count of occurrences of the specified PAPI event. This counter is available only if the configuration time constant HPX_WITH_PAPI is set to ON (default: OFF).

Table 2.101: Performance counter /statistics/average

Counter type	/statistics/average
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current average (mean) value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.

Table 2.102: Performance counter /statistics/rolling_average

Counter type	/statistics/rolling_average
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current rolling average (mean) value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to three comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value will be interpreted as the size of the rolling window (the number of latest values to use to calculate the rolling average). The default value for this is 10. The third value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.

Table 2.103: Performance counter `/statistics/stddev`

Counter type	`/statistics/stddev`
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current standard deviation (stddev) value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume `1000` [ms] as the default. The second value can be either `0` or `1` and specifies whether the underlying counter should be reset during evaluation `1` or not `0`. The default value is `0`.

Table 2.104: Performance counter `/statistics/rolling_stddev`

Counter type	`/statistics/rolling_stddev`
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current rolling variance (stddev) value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to three comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume `1000` [ms] as the default. The second value will be interpreted as the size of the rolling window (the number of latest values to use to calculate the rolling average). The default value for this is `10`. The third value can be either `0` or `1` and specifies whether the underlying counter should be reset during evaluation `1` or not `0`. The default value is `0`.

Table 2.105: Performance counter `/statistics/median`

Counter type	`/statistics/median`
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current (statistically estimated) median value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume `1000` [ms] as the default. The second value can be either `0` or `1` and specifies whether the underlying counter should be reset during evaluation `1` or not `0`. The default value is `0`.

Table 2.106: Performance counter /statistics/max

Counter type	/statistics/max
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current maximum value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.

Table 2.107: Performance counter /statistics/rolling_max

Counter type	/statistics/rolling_max
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current rolling maximum value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to three comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value will be interpreted as the size of the rolling window (the number of latest values to use to calculate the rolling average). The default value for this is 10. The third value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.

Table 2.108: Performance counter /statistics/min

Counter type	/statistics/min
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current minimum value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.

Table 2.109: Performance counter `/statistics/rolling_min`

Counter type	`/statistics/rolling_min`
Counter instance formatting	Any full performance counter name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.
Description	Returns the current rolling minimum value calculated based on the values queried from the underlying counter (the one specified as the instance name).
Parameters	Any parameter will be interpreted as a list of up to three comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume `1000` [ms] as the default. The second value will be interpreted as the size of the rolling window (the number of latest values to use to calculate the rolling average). The default value for this is `10`. The third value can be either `0` or `1` and specifies whether the underlying counter should be reset during evaluation `1` or not `0`. The default value is `0`.

Table 2.110: Performance counter `/arithmetics/add`

Counter type	`/arithmetics/add`
Description	Returns the sum calculated based on the values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.111: Performance counter `/arithmetics/subtract`

Counter type	`/arithmetics/subtract`
Description	Returns the difference calculated based on the values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.112: Performance counter `/arithmetics/multiply`

Counter type	`/arithmetics/multiply`
Description	Returns the product calculated based on the values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.113: Performance counter `/arithmetics/divide`

Counter type	`/arithmetics/divide`
Description	Returns the result of division of the values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.114: Performance counter `/arithmetics/mean`

Counter type	`/arithmetics/mean`
Description	Returns the average value of all values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.115: Performance counter `/arithmetics/variance`

Counter type	`/arithmetics/variance`
Description	Returns the standard deviation of all values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.116: Performance counter `/arithmetics/median`

Counter type	`/arithmetics/median`
Description	Returns the median value of all values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.117: Performance counter `/arithmetics/min`

Counter type	`/arithmetics/min`
Description	Returns the minimum value of all values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.118: Performance counter `/arithmetics/max`

Counter type	`/arithmetics/max`
Description	Returns the maximum value of all values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Table 2.119: Performance counter `/arithmetics/count`

Counter type	`/arithmetics/count`
Description	Returns the count value of all values queried from the underlying counters (the ones specified as the parameters).
Parameters	The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.

Note

The `/arithmetics` counters can consume an arbitrary number of other counters. For this reason those have to be specified as parameters (a comma separated list of counters appended after a `'@'`). For instance:

```
$ ./bin/hello_world_distributed -t2 \
    --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative \
    --hpx:print-counter=/arithmetics/add@/threads{locality#0/worker-thread#*}/count/
↪cumulative
hello world from OS-thread 0 on locality 0
hello world from OS-thread 1 on locality 0
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.515640,[s],25
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.515520,[s],36
/arithmetics/add@/threads{locality#0/worker-thread#*}/count/cumulative,1,0.516445,[s],
↪64
```

Since all wildcards in the parameters are expanded, this example is fully equivalent to specifying both counters separately to `/arithmetics/add`:

```
$ ./bin/hello_world_distributed -t2 \
    --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative \
    --hpx:print-counter=/arithmetics/add@\
        /threads{locality#0/worker-thread#0}/count/cumulative,\
        /threads{locality#0/worker-thread#1}/count/cumulative
```

Table 2.120: Performance counter `/coalescing/count/parcels`

Counter type	`/coalescing/count/parcels`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of parcels for the given action should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of parcels handled by the message handler associated with the action which is given by the counter parameter.
Parameters	The action type. This is the string which has been used while registering the action with *HPX*, e.g. which has been passed as the second parameter to the macro *`HPX_REGISTER_ACTION`* or *`HPX_REGISTER_ACTION_ID`*.

Table 2.121: Performance counter `/coalescing/count/messages`

Counter type	`/coalescing/count/messages`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of messages for the given action should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the number of messages generated by the message handler associated with the action which is given by the counter parameter.
Parameters	The action type. This is the string which has been used while registering the action with *HPX*, e.g. which has been passed as the second parameter to the macro `HPX_REGISTER_ACTION` or `HPX_REGISTER_ACTION_ID`.

Table 2.122: Performance counter `/coalescing/count/average-parcels-per-message`

Counter type	`/coalescing/count/average-parcels-per-message`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the number of messages for the given action should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the average number of parcels sent in a message generated by the message handler associated with the action which is given by the counter parameter.
Parameters	The action type. This is the string which has been used while registering the action with *HPX*, e.g. which has been passed as the second parameter to the macro `HPX_REGISTER_ACTION` or `HPX_REGISTER_ACTION_ID`

Table 2.123: Performance counter `/coalescing/time/average-parcel-arrival`

Counter type	`/coalescing/time/average-parcel-arrival`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the average time between parcels for the given action should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns the average time between arriving parcels for the action which is given by the counter parameter.
Parameters	The action type. This is the string which has been used while registering the action with *HPX*, e.g. which has been passed as the second parameter to the macro `HPX_REGISTER_ACTION` or `HPX_REGISTER_ACTION_ID`

Table 2.124: Performance counter /coalescing/time/parcel-arrival-histogram

Counter type	`/coalescing/time/parcel-arrival-histogram`
Counter instance formatting	`locality#*/total` where: * is the *locality* id of the *locality* the average time between parcels for the given action should be queried for. The *locality* id is a (zero based) number identifying the *locality*.
Description	Returns a histogram representing the times between arriving parcels for the action which is given by the counter parameter. This counter returns an array of values, where the first three values represent the three parameters used for the histogram followed by one value for each of the histogram buckets. The first unit of measure displayed for this counter `[ns]` refers to the lower and upper boundary values in the returned histogram data only. The second unit of measure displayed `[0.1%]` refers to the actual histogram data. For each bucket the counter shows a value between `0` and `1000` which corresponds to a percentage value between `0%` and `100%`.
Parameters	The action type and optional histogram parameters. The action type is the string which has been used while registering the action with *HPX*, e.g. which has been passed as the second parameter to the macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID*. The action type may be followed by a comma separated list of up-to three numbers: the lower and upper boundaries for the collected histogram, and the number of buckets for the histogram to generate. By default these three numbers will be assumed to be `0` (`[ns]`, lower bound), `1000000` (`[ns]`, upper bound), and `20` (number of buckets to generate).

Note

The performance counters related to *parcel* coalescing are available only if the configuration time constant `HPX_WITH_PARCEL_COALESCING` is set to `ON` (default: `ON`). However, even in this case it will be available only for actions that are enabled for parcel coalescing (see the macros `HPX_ACTION_USES_MESSAGE_COALESCING` and `HPX_ACTION_USES_MESSAGE_COALESCING_NOTHROW`).

APEX integration

HPX provides integration with APEX[184], which is a framework for application profiling using task timers and various performance counters Huck *et al.*[194]. It can be added as a `git` submodule by turning on the option *HPX_WITH_APEX:BOOL* during CMake[185] configuration. TAU[186] is an optional dependency when using APEX.

To build *HPX* with APEX[187], add *HPX_WITH_APEX*=`ON`, and, optionally, `Tau_ROOT=$PATH_TO_TAU` to your CMake[188] configuration. In addition, you can override the tag used for APEX[189] with the `HPX_WITH_APEX_TAG` option. Please see the APEX *HPX* documentation[190] for detailed instructions on using APEX[191] with *HPX*.

Tracy integration

HPX provides integration with the Tracy[192] profiler, which offers per-thread zone tracking, message logs, and fiber support. Enable it with *HPX_WITH_TRACY*=ON during CMake[193] configuration.

Tracy can be supplied via a system install (point `Tracy_ROOT` at the install tree) or fetched by CMake at configure time by adding `HPX_WITH_FETCH_TRACY=ON`. The version fetched is pinned by `HPX_WITH_TRACY_TAG`, which defaults to `v0.14.1`. When Tracy is fetched, *HPX* forces `TRACY_ENABLE`, `TRACY_ON_DEMAND` and `TRACY_FIBERS` on the built client. A system-supplied Tracy must have been built with the same three options; Tracy 0.14 mangles its exported profiler symbol based on the active define set, so a mismatch fails at link time rather than producing a silent inconsistency at runtime.

To profile a distributed run, additionally enable *HPX_WITH_PARCEL_PROFILING*=ON so per-parcel identifiers are carried on the wire and the `send_parcel` / `recv_parcel` / `parcel_scheduled` events can be correlated across localities by parcel id.

Event classes can be compiled out individually to reduce the tracing cost when only a subset of the timeline is being investigated: *HPX_WITH_TRACING_LIFECYCLE_EVENTS*, *HPX_WITH_TRACING_CAUSAL_EVENTS*, and *HPX_WITH_TRACING_WORK_STEALING_EVENTS*. All three default to `ON`; turning one off compiles the wrapper for that class to a no-op, so the runtime connection check and the event body do not run (argument evaluation at each call site is unchanged). These gates affect the Tracy backend, which is the only backend that emits these classes today; the APEX, ITT-Notify and empty backends already treat all three as no-ops.

Start `tracy-profiler` (or `tracy-capture` for headless capture) before or during the run. Tracy discovers instrumented processes via UDP broadcast on the local network; no port configuration is required for the common case.

2.4.16 Using the LCI parcelport

Basic information

The Lightweight Communication Interface[195] (LCI) is an ongoing research project aiming to provide efficient support for applications with irregular and asynchronous communication patterns such as graph analysis, sparse linear algebra, and task-based runtime on modern parallel architectures. Its features include (a) support for more communication primitives such as two-sided send/recv and one-sided (dynamic or direct) remote put/get (b) better multi-threaded performance (c) explicit user control of communication resource (d) flexible signaling mechanisms such as synchronizer, completion queue, and active message handler. It is designed to be a low-level communication library used by high-level libraries and frameworks.

The LCI parcelport is an experimental parcelport. It aims to provide the best possible communication performance on high-performance computation platforms. Compared to the MPI parcelport, it uses much fewer messages and memory copies to transfer an *HPX* parcel over the network. Its message transmission path involves minimum synchronization points and is almost lock-free. It is expected to be much faster than the MPI parcelport.

[192] https://github.com/wolfpld/tracy
[193] https://www.cmake.org
[195] https://github.com/uiuc-hpc/lci

Build *HPX* with the LCI parcelport

While building *HPX*, you can specify a set of CMake[196] variables to enable and configure the LCI parcelport. Below, there is a set of the most important and frequently used CMake variables.

HPX_WITH_PARCELPORT_LCI

Enable the LCI parcelport. This enables the use of LCI for networking operations in the *HPX* runtime. The default value is `OFF` because it's not available on all systems and/or requires another dependency. However, this experimental parcelport may provide better performance than the MPI parcelport. You must set this variable to `ON` in order to use the LCI parcelport. All the following variables only make sense when this variable is set to `ON`.

HPX_WITH_FETCH_LCI

Use FetchContent to fetch LCI. The default value is `OFF`. If this option is set to `OFF`. You need to install your own LCI library and *HPX* will try to find it using CMake[197] `find_package`. You can specify the location of the LCI installation by the environmental variable `LCI_ROOT`. Refer to the LCI README[198] for how to install LCI. If this option is set to `ON`. *HPX* will fetch and build LCI for you. You can use the following CMake[199] variables to configure this behavior for your platform.

HPX_WITH_LCI_TAG

This variable only takes effect when `HPX_WITH_FETCH_LCI` is set to `ON` and `FETCHCONTENT_SOURCE_DIR_LCI` is not set. *HPX* will fetch LCI from its github repository. This variable controls the branch/tag LCI will be fetched.

FETCHCONTENT_SOURCE_DIR_LCI

This variable only takes effect when `HPX_WITH_FETCH_LCI` is set to `ON`. When it is defined, `HPX_WITH_LCI_TAG` will be ignored. It accepts a path to a local version of LCI source code and *HPX* will fetch and build LCI from there. The default value is set conservatively for the stability of *HPX*, but users are welcome to set this variable to `master` for potentially better performance.

Run *HPX* with the LCI parcelport

We use the same mechanisms as MPI to launch LCI, so you can use the same way you run MPI parcelport to run LCI parcelport. Typically, it would be `hpxrun.py`, `mpirun`, or `srun`.

`hpxrun.py` serves as a wrapper for `mpirun` and `srun`. If you are using `hpxrun.py`, pass `-p lci` to the scripts. You also need to pass either `-r mpi` or `-r srun` to select the correct run wrapper according to the platform.

If you are using `mpirun` or `srun`, you can just pass `--hpx:ini=hpx.parcel.lci.priority=1000`, `--hpx:ini=hpx.parcel.lci.enable=1`, and `--hpx:ini=hpx.parcel.bootstrap=lci` to the *HPX* applications.

The `hpxrun.py` argument `-r none` (the default option for the run wrapper) and its corresponding *HPX* arguments `--hpx:hpx` and `--hpx:agas` do not work for the MPI or the LCI parcelport.

196 https://www.cmake.org
197 https://www.cmake.org
198 https://github.com/uiuc-hpc/lci#readme
199 https://www.cmake.org

Performance tuning of the LCI parcelport

We encourage users to set the following environmental variables when using the LCI parcelport to get better performance.

```
$ export LCI_SERVER_MAX_SENDS=1024
$ export LCI_SERVER_MAX_RECVS=4096
$ export LCI_SERVER_NUM_PKTS=65536
$ export LCI_SERVER_MAX_CQES=65536
$ export LCI_PACKET_SIZE=12288
```

This setting needs roughly 800MB memory per process. The memory consumption mainly comes from the packets, which can be calculated using *LCI_SERVER_NUM_PKTS x LCI_PACKET_SIZE*.

In addition, users can tune the following command-line options when using the LCI parcelport to get better performance.

--hpx:ini=hpx.parcel.lci.ndevices=<int>

The number of LCI devices to use. The default value is 2. An LCI device represents a collection of network resources. More devices lead to lower thread contention, but too many devices may lead to load imbalance or hardware overhead.

--hpx:ini=hpx.parcel.lci.progress_type=<worker|rp>

The way to progress the LCI device. The default value is `worker`. The `worker` option uses all worker threads to progress the LCI devices. The `rp` option uses dedicated pinned threads to progress the LCI devices. Normally, the `worker` option gives better performance, but the `rp` option has been observed with better performance on some clusters with prior generation of InfiniBand hardware.

2.4.17 Using the LCW parcelport

Basic information

The LCW parcelport is an advanced MPI parcelport that can utilize the MPICH VCI and Continuation extensions. The exact MPI implementation is wrapped in a thin wrapper layer (the Lightweight Communication Wrapper, or LCW). This wrapper provides an active message, send/recv, completion queue, and device abstraction on top of MPI (with/without extensions), GASNet-EX, and LCI. The GASNet-EX backend of LCW cannot be used in *HPX* for now, as it lacks send/recv support.

Build *HPX* with the LCW parcelport

While building *HPX*, you can specify a set of CMake[200] variables to enable and configure the LCW parcelport. Below, there is a set of the most important and frequently used CMake variables.

HPX_WITH_PARCELPORT_LCW

Enable the LCW parcelport. This enables the use of LCW for networking operations in the *HPX* runtime. The default value is `OFF` because it's not available on all systems and/or requires another dependency. You must set this variable to `ON` in order to use the LCW parcelport. All the following variables only make sense when this variable is set to `ON`.

HPX_WITH_FETCH_LCW

Use FetchContent to fetch LCW. The default value is `OFF`. If this option is set to `OFF`. You need to install your own LCW library and *HPX* will try to find it using CMake[201] `find_package`. You can specify the location of the LCW installation by the environmental variable `LCW_ROOT`. Refer to the LCW README[202] for how to install LCW. If this option is set to `ON`. *HPX* will fetch and build LCW for you. You can use the following CMake[203] variables to configure this behavior for your platform.

HPX_WITH_LCW_TAG

This variable only takes effect when `HPX_WITH_FETCH_LCW` is set to `ON` and `FETCHCONTENT_SOURCE_DIR_LCW` is not set. *HPX* will fetch LCW from its github repository. This variable controls the branch/tag LCW will be fetched.

FETCHCONTENT_SOURCE_DIR_LCW

This variable only takes effect when `HPX_WITH_FETCH_LCW` is set to `ON`. When it is defined, `HPX_WITH_LCW_TAG` will be ignored. It accepts a path to a local version of LCW source code and *HPX* will fetch and build LCW from there.

Run *HPX* with the LCW parcelport

You can configure runtime behavior with the following options.

--hpx:ini=hpx.parcel.lcw.ndevices=<n>

The number of LCW devices to use (default: 2). Each LCW device maps to an MPI communicator or an LCI device. When the MPICH VCI extension is enabled, each MPI communicator will be mapped to a dedicated collection of network resources. More devices lead to lower thread contention, but too many devices may lead to load imbalance or hardware overhead.

2.4.18 *HPX* runtime and resources

HPX thread scheduling policies

The *HPX* runtime has six thread scheduling policies: local-priority, static-priority, local, static, local-workrequesting-fifo, and abp-priority. These policies can be specified from the command line using the command line option *--hpx:queuing*. In order to use a particular scheduling policy, the runtime system must be built with the appropriate scheduler flag turned on (e.g. `cmake -DHPX_THREAD_SCHEDULERS=local`, see *CMake options* for more information).

Priority local scheduling policy (default policy)

The priority local scheduling policy maintains one queue per operating system (OS) thread. The OS thread pulls its work from this queue. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using *--hpx:high-priority-threads*. High priority threads are executed by any of the OS threads before any other work is executed. When a queue is empty, work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work.

For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option *--hpx:numa-sensitive*. When NUMA sensitivity is turned on, work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler is enabled at build time by default using the FIFO (first-in-first-out) queueing policy. This policy can be invoked using *--hpx:queuing*`local-priority-fifo`. The scheduler can also be enabled using the LIFO (last-in-first-out) policy. This is not the default policy and must be invoked using the command line option *--hpx:queuing*`local-priority-lifo`.

Static priority scheduling policy

- invoke using: *--hpx:queuing*`static-priority` (or `-qs`)

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

Local scheduling policy

- invoke using: *--hpx:queuing*`local` (or `-ql`)
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=local`

The local scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads).

Static scheduling policy

- invoke using: *--hpx:queuing*`static`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=static`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

Priority ABP scheduling policy

- invoke using: `--hpx:queuingabp-priority-fifo`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=abp-priority`

Priority ABP policy maintains a double ended lock free queue for each OS thread. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using `--hpx:high-priority-threads`. High priority threads are executed by the first OS threads before any other work is executed. When a queue is empty work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work. For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option `--hpx:numa-sensitive`. When NUMA sensitivity is turned on work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler can be used with two underlying queuing policies (FIFO: first-in-first-out, and LIFO: last-in-first-out). In order to use the LIFO policy use the command line option `--hpx:queuingabp-priority-lifo`.

Work requesting scheduling policies

- invoke using: `--hpx:queuinglocal-workrequesting-fifo`, using `--hpx:queuinglocal-workrequesting-lifo`, or using `--hpx:queuinglocal-workrequesting-mc`

The work-requesting policies rely on a different mechanism of balancing work between cores (compared to the other policies listed above). Instead of actively trying to steal work from other cores, requesting work relies on a less disruptive mechanism. If a core runs out of work, instead of actively looking at the queues of neighboring cores, in this case a request is posted to another core. This core now (whenever it is not busy with other work) either responds to the original core by sending back work or passes the request on to the next possible core in the system. In general, this scheme avoids contention on the work queues as those are always accessed by their own cores only.

The *HPX* resource partitioner

The *HPX* resource partitioner lets you take the execution resources available on a system—processing units, cores, and numa domains—and assign them to thread pools. By default *HPX* creates a single thread pool name `default`. While this is good for most use cases, the resource partitioner lets you create multiple thread pools with custom resources and options.

Creating custom thread pools is useful for cases where you have tasks which absolutely need to run without interference from other tasks. An example of this is when using MPI[204] for distribution instead of the built-in mechanisms in *HPX* (useful in legacy applications). In this case one can create a thread pool containing a single thread for MPI communication. MPI tasks will then always run on the same thread, instead of potentially being stuck in a queue behind other threads.

Note that *HPX* thread pools are completely independent from each other in the sense that task stealing will never happen between different thread pools. However, tasks running on a particular thread pool can schedule tasks on another thread pool.

> **Note**
>
> It is simpler in some situations to schedule important tasks with high priority instead of using a separate thread pool.

204 https://en.wikipedia.org/wiki/Message_Passing_Interface

Using the resource partitioner

The `hpx::resource::partitioner` is now created during *HPX* runtime initialization without explicit action needed from the user. To specify some of the initialization parameters you can use the *hpx::init_params*.

The resource partitioner callback is the interface to add thread pools to the *HPX* runtime and to assign resources to the thread pools. In order to create custom thread pools you can specify the resource partitioner callback `hpx::init_params::rp_callback` which will be called once the resource partitioner will be created , see the example below. You can also specify other parameters, see *hpx::init_params*.

To add a thread pool use the `hpx::resource::partitioner::create_thread_pool` method. If you simply want to use the default scheduler and scheduler options, it is enough to call `rp.create_thread_pool("my-thread-pool")`.

Then, to add resources to the thread pool you can use the `hpx::resource::partitioner::add_resource` method. The resource partitioner exposes the hardware topology retrieved using Portable Hardware Locality (HWLOC)[205] and lets you iterate through the topology to add the wanted processing units to the thread pool. Below is an example of adding all processing units from the first NUMA domain to a custom thread pool, unless there is only one NUMA domain in which case we leave the first processing unit for the default thread pool:

Note

Whatever processing units are not assigned to a thread pool by the time *hpx::init* is called will be added to the default thread pool. It is also possible to explicitly add processing units to the default thread pool, and to create the default thread pool manually (in order to e.g. set the scheduler type).

Tip

The command line option `--hpx:print-bind` is useful for checking that the thread pools have been set up the way you expect.

Difference between the old and new version

In the old version, you had to create an instance of the `resource_partitioner` with `argc` and `argv`.

```
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);
    hpx::init();
}
```

From *HPX* 1.5.0 onwards, you just pass `argc` and `argv` to `hpx::init()` or `hpx::start()` for the binding options to be parsed by the resource partitioner.

```
int main(int argc, char** argv)
{
    hpx::init_params init_args;
    hpx::init(argc, argv, init_args);
}
```

[205] https://www.open-mpi.org/projects/hwloc/

In the old version, when creating a custom thread pool, you just called the utilities on the resource partitioner instantiated previously.

```
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);

    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }

    hpx::init();
}
```

You now specify the resource partitioner callback which will tie the resources to the resource partitioner created during runtime initialization.

```
void init_resource_partitioner_handler(hpx::resource::partitioner& rp)
{
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
```

(continues on next page)

(continued from previous page)

```
        }
    }
}

int main(int argc, char* argv[])
{
    hpx::init_params init_args;
    init_args.rp_callback = &init_resource_partitioner_handler;

    hpx::init(argc, argv, init_args);
}
```

Advanced usage

It is possible to customize the built in schedulers by passing scheduler options to `hpx::resource::partitioner::create_thread_pool`. It is also possible to create and use custom schedulers.

Note

It is not recommended to create your own scheduler. The *HPX* developers use this to experiment with new scheduler designs before making them available to users via the standard mechanisms of choosing a scheduler (command line options). If you would like to experiment with a custom scheduler the resource partitioner example `shared_priority_queue_scheduler.cpp` contains a fully implemented scheduler with logging, etc. to make exploration easier.

To choose a scheduler and custom mode for a thread pool, pass additional options when creating the thread pool like this:

```
rp.create_thread_pool("my-thread-pool",
    hpx::resource::policies::local_priority_lifo,
    hpx::policies::scheduler_mode(
        hpx::policies::scheduler_mode::default |
        hpx::policies::scheduler_mode::enable_elasticity));
```

The available schedulers are documented here: `hpx::resource::scheduling_policy`, and the available scheduler modes here: `hpx::threads::policies::scheduler_mode`. Also see the examples folder for examples of advanced resource partitioner usage: `simple_resource_partitioner.cpp` and `oversubscribing_resource_partitioner.cpp`.

2.4.19 Executors

Executors in *HPX* provide a flexible way to control **how, when, and where** tasks are executed. Instead of manually creating threads or managing thread pools, you can hand your tasks to an executor, and it takes care of the details of running them.

This page introduces the concept of executors, the main types available in *HPX*, and how to create custom executors.

What is an executor?

An **executor** is an abstraction that separates the *what* from the *how* of task execution:

- **What**: the work to be performed (e.g. a function or task).
- **How**: whether the task runs synchronously, asynchronously, or in parallel across multiple cores.

By using executors, you can switch between execution strategies without rewriting your algorithms. *HPX* provides a rich set of executors with a unified API.

Main Executors in *HPX*

HPX provides multiple executors. Below are three of the most commonly used:

Parallel Executor

- Default in *HPX*.
- Creates a new HPX thread for every scheduled task.
- Works well for large tasks, but frequent small tasks incur overhead due to thread creation/destruction.

```
#include <hpx/execution.hpp>
#include <hpx/algorithm.hpp>
#include <vector>

std::vector<int> data(100, 1);

hpx::for_each(
    hpx::execution::par,
    data.begin(), data.end(),
    [](int &x) {
        x += 1;
    }
);
```

Fork-Join Executor

- Spawns one thread per CPU core when created.
- Threads are reused across tasks, avoiding repeated creation costs.
- Efficient for workloads with many sequential parallel regions.
- May waste resources if parallel work is limited.

```
#include <hpx/execution.hpp>
#include <hpx/algorithm.hpp>
#include <vector>

std::vector<int> data(100, 1);

hpx::execution::experimental::fork_join_executor exec;

hpx::for_each(
    hpx::execution::par.on(exec),
    data.begin(), data.end(),
    [](int &x) {
        x += 1;
    }
);
```

Sequential Executor

- Executes all tasks synchronously on the calling thread.
- Useful for debugging (deterministic execution) or when parallelism brings no benefit.
- Maintains the same executor-based API while running tasks sequentially.

```
#include <hpx/execution.hpp>
#include <hpx/algorithm.hpp>
#include <vector>

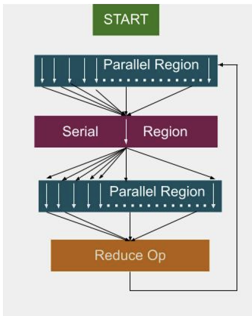
std::vector<int> data(100, 1);

hpx::execution::sequenced_executor seq_exec;

hpx::for_each(
    hpx::execution::seq.on(seq_exec),
    data.begin(), data.end(),
    [](int &x) { x += 1; }
);
```

Executors in real-world applications

A practical example is the **LULESH** mini-application (a hydrodynamics benchmark).



- With the **parallel executor**, each parallel loop creates and destroys new threads, introducing overhead.
- With the **fork-join executor**, threads are created once and reused across loops, reducing overhead and improving performance.

In studies, the fork-join executor achieved significant speedups, in some cases more than twice as fast as traditional OpenMP implementations.

Fig. 2.11:
threads for e

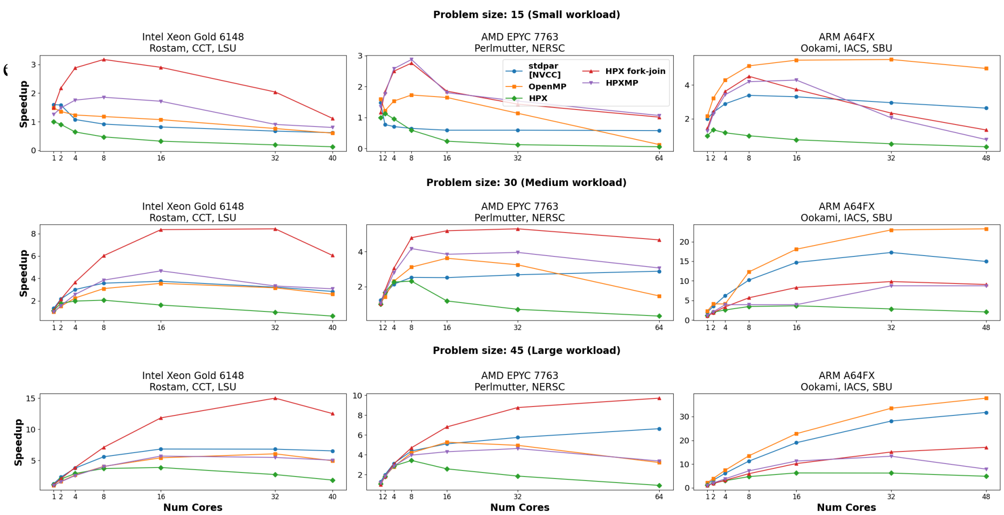


Fig. 2.13: Performance comparison between executors in the LULESH benchmark.

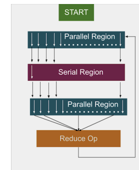
Custom executors

While *HPX* provides a variety of built-in executors, you may sometimes need to adapt task execution to your own requirements. This is where **custom executors** come in. By writing a small wrapper around an existing executor, you can extend its behavior?for example, to add logging, profiling information, or special scheduling rules?while still taking advantage of the *HPX* executor API.

Custom annotating executor



The following example shows how to implement a simple executor that annotates tasks with a string label for easier debugging and profiling.

> **Note**
>
> Annotations do not affect how tasks run or what results they produce. Their main purpose is to give human-readable names to tasks so that they can be identified in profilers, and debuggers.

Full example code

```
#include <hpx/hpx_main.hpp>
#include <hpx/include/parallel_executors.hpp>
#include <hpx/include/async.hpp>
#include <hpx/execution.hpp>
#include <hpx/modules/async_base.hpp>
#include <hpx/modules/threading_base.hpp>

#include <iostream>
#include <string>
#include <utility>

template <typename BaseExecutor>
struct simple_annotating_executor
{
    BaseExecutor base_;
    const char* annotation_;

    simple_annotating_executor(BaseExecutor exec, const char* ann)
        : base_(std::move(exec)), annotation_(ann)
    {}

    // Non-blocking one-way executor
    template <typename F, typename... Ts>
    friend void tag_invoke(hpx::parallel::execution::post_t,
                           simple_annotating_executor const& exec,
                           F&& f, Ts&&... ts)
    {
        hpx::post(
            hpx::annotated_function(std::forward<F>(f), exec.annotation_),
            std::forward<Ts>(ts)...);
    }

    // Synchronous execution
    template <typename F, typename... Ts>
    friend auto tag_invoke(hpx::parallel::execution::sync_execute_t,
```

(continues on next page)

(continued from previous page)

```
                          simple_annotating_executor const& exec,
                          F&& f, Ts&&... ts)
    {
        return hpx::parallel::execution::sync_execute(
            exec.base_,
         ␣
↪   hpx::annotated_function(std::forward<F>(f), exec.annotation_),
            std::forward<Ts>(ts)...);
    }
};

// Example functions
int compute_square(int x)
{
    std::cout << "[sync_execute] Running task with annotation\n";
    return x * x;
}

void say_hello()
{
    std::cout << "[post] Running task with annotation\n";
}

int main()
{
    simple_annotating_executor␣
↪exec(hpx::execution::parallel_executor{}, "my_custom_task");

    // Synchronous execution
    int result = hpx::parallel::execution::sync_
↪execute(exec, &compute_square, 7);
    std::cout << "Result from sync_execute: " << result << "\n";

    // Post a task
    hpx::parallel::execution::post(exec, &say_hello);

    return 0;
}
```

Explanation

The first lines pull in the necessary HPX headers for executors, asynchronous execution, and annotated functions. The key one here is *hpx/threading_base/annotated_function.hpp*, which provides the facility to tag tasks with a string label. We then define a simple_annotating_executor that wraps another executor and associates an annotation string with every task:

```
template <typename BaseExecutor>
struct simple_annotating_executor
{
    BaseExecutor base_;
```

(continues on next page)

(continued from previous page)

```
    const char* annotation_;

    simple_annotating_executor(BaseExecutor exec, const char* ann)
        : base_(std::move(exec)), annotation_(ann)
    {}
};
```

The post customization schedules a task to run asynchronously. We wrap the task in *hpx::annotated_function* so that it carries the annotation. Executors in HPX customize these operations through *tag_invoke* overloads, which are selected by special tag objects like *post_t*` and *sync_execute_t*. This is why the executor interface may look different from a normal member function API.

```
template <typename F, typename... Ts>
friend void tag_invoke(hpx::parallel::execution::post_t,
                       simple_annotating_executor const& exec,
                       F&& f, Ts&&... ts)
{
    hpx::post(
     ␣
↪   hpx::annotated_function(std::forward<F>(f), exec.annotation_),
        std::forward<Ts>(ts)...);
}
```

The *sync_execute* customization runs a task immediately and returns the result. Again, we wrap the function with an annotation before executing. The key difference is that *post* schedules a task in a fire-and-forget style (no result is returned), while *sync_execute* blocks until the task finishes and gives you the result back.

```
template <typename F, typename... Ts>
friend auto tag_invoke(hpx::parallel::execution::sync_execute_t,
                       simple_annotating_executor const& exec,
                       F&& f, Ts&&... ts)
{
    return hpx::parallel::execution::sync_execute(
        exec.base_,
     ␣
↪   hpx::annotated_function(std::forward<F>(f), exec.annotation_),
        std::forward<Ts>(ts)...);
}
```

Note how we delegate the actual execution to *exec.base_*, the underlying executor. This makes the custom executor lightweight: it only adds annotations, while leaving the scheduling strategy to the base executor (here, a *parallel_executor*).

We define two simple functions to demonstrate both synchronous and asynchronous execution: These functions also print to *std::cout*, but this output is not the actual annotation. Annotations are stored internally by HPX and become visible when you use debugging or profiling tools.

```
int compute_square(int x)
{
    std::cout << "[sync_execute] Running task with annotation\n";
```

(continues on next page)

(continued from previous page)

```
    return x * x;
}

void say_hello()
{
    std::cout << "[post] Running task with annotation\n";
}
```

Finally, in main we create the executor with a base executor and annotation string. We then run one task with sync_execute (blocking, returns result) and one with post (asynchronous, fire-and-forget). You can also create multiple annotating executors with different strings, so each task gets its own label. This is especially useful in larger applications with many different kinds of tasks, where annotations make it much easier to trace what is happening.

```
int main()
{
    simple_annotating_executor␣
↪exec(hpx::execution::parallel_executor{}, "my_custom_task");

    // Synchronous execution
    int result = hpx::parallel::execution::sync_
↪execute(exec, &compute_square, 7);
    std::cout << "Result from sync_execute: " << result << "\n";

    // Post a task
    hpx::parallel::execution::post(exec, &say_hello);

    return 0;
}
```

Custom annotating executor with parallel algorithms

The following example demonstrates how to use a custom annotating executor with *HPX* parallel algorithms, such as *for_each*. This allows you to attach annotations to tasks while executing them in parallel.

Full example code

```
#include <hpx/execution.hpp>
#include <hpx/hpx_main.hpp>
#include <hpx/include/parallel_algorithm.hpp>
#include <hpx/include/parallel_executors.hpp>
#include <hpx/modules/threading_base.hpp>

#include <iostream>
#include <utility>
#include <vector>
```

(continues on next page)

(continued from previous page)

```
template <typename BaseExecutor>
struct simple_annotating_executor
{
    BaseExecutor base_;
    char const* annotation_;

    using execution_category =
        hpx::traits::executor_execution_category_t<BaseExecutor>;

    simple_annotating_executor(BaseExecutor exec, char const* ann)
    : base_(std::move(exec))
    , annotation_(ann)
    {
    }

    // Bulk async_execute (used by parallel algorithms)
    template <typename F, typename Shape, typename... Ts>
    friend␣
↪auto tag_invoke(hpx::parallel::execution::bulk_async_execute_t,
        simple_
↪annotating_executor const& exec, F&& f, Shape const& shape,
        Ts&&... ts)
    {
        return hpx::parallel::execution::bulk_async_execute(
            exec.base_,
                ␣
↪   hpx::annotated_function(std::forward<F>(f), exec.annotation_),
            shape, std::forward<Ts>(ts)...);
    }
};

namespace hpx::execution::experimental {

    // The␣
↪annotating executor exposes the same executor categories as its
    // underlying (wrapped) executor.

    template <typename BaseExecutor>
    struct␣
↪is_two_way_executor<simple_annotating_executor<BaseExecutor>>
    : is_two_way_executor<BaseExecutor>
    {
    };
}    // namespace hpx::execution::experimental

int main()
{
    using base_executor = hpx::execution::parallel_executor;
    simple_
↪annotating_executor exec(base_executor{}, "for_each_task");

    std::vector<int> data = {1, 2, 3, 4, 5};
```

(continues on next page)

(continued from previous page)

```
    // Use the custom executor with a parallel algorithm
    hpx::for_
↪each(hpx::execution::par.on(exec),    // attach executor
        data.begin(), data.end(), [](int& x) {
            std::cout << "Processing " << x << " on thread "
                    << hpx::get_worker_thread_num() << "\n";
            x *= x;
        });

    std::cout << "Squared values: ";
    for (int v : data)
        std::cout << v << " ";
    std::cout << "\n";

    return 0;
}
```

Explanation

Similar as before, the first lines pull in the necessary HPX headers for executors, asynchronous execution, and annotated functions. The key one here is *hpx/threading_base/annotated_function.hpp*, which provides the facility to tag tasks with a string label. We then define a simple_annotating_executor that wraps another executor and associates an annotation string with every task:

```
template <typename BaseExecutor>
struct simple_annotating_executor
{
    BaseExecutor base_;
    const char* annotation_;

    using execution_category =
        hpx::traits::executor_execution_category_t<BaseExecutor>;

    simple_annotating_executor(BaseExecutor exec, const char* ann)
        : base_(std::move(exec)), annotation_(ann)
    {}
};
```

Note that we expose the execution category of the custom executor with *using execution_category = hpx::traits::executor_execution_category_t<BaseExecutor>*. We inherit the execution category from the underlying executor (*BaseExecutor`*), which ensures that our *simple_annotating_executor* behaves like the base executor in terms of parallelism and task execution capabilities.

The *bulk_async_execute* customization schedules a set of tasks to run asynchronously. We wrap each task in *hpx::annotated_function* so that it carries the annotation. Executors in *HPX* customize these operations through *tag_invoke* overloads, which are selected by special tag objects like *bulk_async_execute_t*. This is why the executor interface may look different from a normal member function API - it uses tag dispatch to integrate seamlessly with the *HPX* parallel algorithms infrastructure.

```
template <typename F, typename Shape, typename... Ts>
friend␣
↪auto tag_invoke(hpx::parallel::execution::bulk_async_execute_t,
    simple_
↪annotating_executor const& exec, F&& f, Shape const& shape,
    Ts&&... ts)
{
    return hpx::parallel::execution::bulk_async_execute(
        exec.base_,
        ␣
↪   hpx::annotated_function(std::forward<F>(f), exec.annotation_),
        shape, std::forward<Ts>(ts)...);
}
```

Note how we delegate the actual execution to *exec.base_*, the underlying executor. This makes the custom executor lightweight: it only adds annotations, while leaving the scheduling strategy to the base executor (here, a *parallel_executor*).

The *hpx::execution::experimental* namespace contains traits that describe executor capabilities, such as whether an executor can run tasks one-way, two-way, or never-blocking. These traits are used internally by *HPX* to verify that an executor is compatible with a given parallel algorithm or execution policy.

```
namespace hpx::execution::experimental {

    // The␣
↪annotating executor exposes the same executor categories as its
    // underlying (wrapped) executor.

    template <typename BaseExecutor>
    struct is_never_blocking_one_way_executor<
        simple_annotating_executor<BaseExecutor>>
    : is_never_blocking_one_way_executor<BaseExecutor>
    {
    };

    template <typename BaseExecutor>
    struct␣
↪is_one_way_executor<simple_annotating_executor<BaseExecutor>>
    : is_one_way_executor<BaseExecutor>
    {
    };

    template <typename BaseExecutor>
    struct␣
↪is_two_way_executor<simple_annotating_executor<BaseExecutor>>
    : is_two_way_executor<BaseExecutor>
    {
    };
}
```

- *is_never_blocking_one_way_executor* indicates whether the executor can schedule tasks in a fire-and-forget style without blocking.
- *is_one_way_executor* indicates support for one-way execution (tasks can be scheduled

but no result is returned).

- *is_two_way_executor* indicates support for two-way execution (tasks return a result or a future).

In all cases, the custom executor inherits the capabilities of the base executor, so it integrates seamlessly with *HPX* algorithms.

This design ensures that *simple_annotating_executor* can be used anywhere its underlying executor could be used, while still adding the annotation functionality. It keeps the custom executor lightweight and fully compatible with the parallel algorithms infrastructure.

In main, we create the executor with a base executor and an annotation string, and then use it with a parallel algorithm:

```
int main()
{
    using base_executor = hpx::execution::parallel_executor;
    simple_
↪annotating_executor exec(base_executor{}, "for_each_task");

    std::vector<int> data = {1, 2, 3, 4, 5};

    // Use the custom executor with a parallel algorithm
    hpx::for_
↪each(hpx::execution::par.on(exec),    // attach executor
        data.begin(), data.end(), [](int& x) {
            std::cout << "Processing " << x << " on thread "
                    << hpx::get_worker_thread_num() << "\n";
            x *= x;
        });

    std::cout << "Squared values: ";
    for (int v : data)
        std::cout << v << " ";
    std::cout << "\n";

    return 0;
}
```

First, we create a base executor (*parallel_executor*) and wrap it in our *simple_annotating_executor*, providing an annotation string “for_each_task”. This custom executor will attach the annotation to every task it schedules, while delegating actual execution to the base executor.

We then use hpx::for_each with a parallel execution policy and attach our custom executor using *par.on(exec)*: * hpx::execution::par.on(exec) attaches our custom executor to the algorithm. * for_each internally partitions the work across threads and schedules each task using *bulk_async_execute*. * Each task is annotated with “for_each_task”, visible in debuggers and profilers. * The results of the parallel computation are stored in the data vector, demonstrating that the algorithm

executed successfully in parallel.

This pattern is especially useful in larger applications with many tasks, as annotations make it much easier to trace and debug the execution of parallel algorithms.

2.4.20 Error handling

Like in any other asynchronous invocation scheme, it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In *HPX* all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation *locality*, where it will be rethrown during synchronization with the calling thread.

The source code for this example can be found here: `error_handling.cpp`.

Working with exceptions

For the following description assume that the function `raise_exception()` is executed by invoking the plain action `raise_exception_type`.

```
void raise_exception()
{
    HPX_THROW_EXCEPTION(
        ␣
↪   hpx::error::no_success, "raise_exception", "simulated error");
}
HPX_PLAIN_ACTION(raise_exception, raise_exception_action)
```

The exception is thrown using the macro *HPX_THROW_EXCEPTION*. The type of the thrown exception is *hpx::exception*. This associates additional diagnostic information with the exception, such as file name and line number, *locality* id and thread id, and stack backtrace from the point where the exception was thrown.

Any exception thrown during the execution of an action is transferred back to the (asynchronous) invocation site. It will be rethrown in this context when the calling thread tries to wait for the result of the action by invoking either `future<>::get()` or the synchronous action invocation wrapper as shown here:

> **Note**
>
> The exception is transferred back to the invocation site even if it is executed on a different *locality*.

Additionally, this example demonstrates how an exception thrown by an (possibly remote) action can be handled. It shows the use of *hpx::diagnostic_information*, which retrieves all available diagnostic information from the exception as a formatted string. This includes, for instance, the name of the source file and line number, the sequence number of the OS thread and the *HPX* thread id, the *locality* id and the stack backtrace of the point where the original exception was thrown.

Under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, *HPX* exposes a set of lower-level functions as demonstrated in the following code snippet:

Working with error codes

Most of the API functions exposed by *HPX* can be invoked in two different modes. By default those will throw an exception on error as described above. However, sometimes it is desirable not to throw an exception in case of an error condition. In this case an object instance of the *hpx::error_code* type can be passed as the last argument to the API function. In case of an error, the error condition will be returned in that *hpx::error_code* instance. The following example demonstrates extracting the full diagnostic information without exception handling:

```
            hpx::cout << "Error reporting using error code\n";

            // Create a new error_code instance.
            hpx::error_code ec;

            // If an␣
↪instance of an error_code is passed as the last argument while
            // invoking␣
↪the action, the function will not throw in case of an error
            // but␣
↪store the error information in this error_code instance instead.
            raise_exception_action do_it;
            do_it(hpx::find_here(), ec);

            if (ec)
            {
                // Print just the essential error information.
                ␣
↪    hpx::cout << "returned error: " << ec.get_message() << "\n";

                //␣
↪Print all of the available diagnostic information as stored with
                // the exception.
                hpx::cout << "diagnostic information:"
   ␣
↪                      << hpx::diagnostic_information(ec) << "\n";
            }

            hpx::cout << std::flush;
```

Note

The error information is transferred back to the invocation site even if it is executed on a different *locality*.

This example show how an error can be handled without having to resolve to exceptions and that the returned *hpx::error_code* instance can be used in a very similar way as the *hpx::exception* type above. Simply pass it to the `hpx::diagnostic_information`, which retrieves all available diagnostic information from the error code instance as a formatted string.

As for handling exceptions, when working with error codes, under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, *HPX* exposes a set of lower-level functions usable with error codes as demonstrated in the following code snippet:

```
␣
↪     hpx::cout << "Detailed error reporting using error code\n";

          // Create a new error_code instance.
          hpx::error_code ec;

          // If an␣
↪instance of an error_code is passed as the last argument while
          // invoking␣
↪the action, the function will not throw in case of an error
          // but␣
↪store the error information in this error_code instance instead.
          raise_exception_action do_it;
          do_it(hpx::find_here(), ec);

          if (ec)
          {
                ␣
↪ // Print the elements of the diagnostic information separately.
            ␣
↪     hpx::cout << "{what}: " << hpx::get_error_what(ec) << "\n";
                ␣
↪hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(ec)
                          << "\n";
            ␣
↪     hpx::cout << "{hostname}: " << hpx::get_error_host_name(ec)
                          << "\n";
                ␣
↪hpx::cout << "{pid}: " << hpx::get_error_process_id(ec) << "\n";
                ␣
↪ hpx::cout << "{function}: " << hpx::get_error_function_name(ec)
                          << "\n";
                ␣
↪hpx::cout << "{file}: " << hpx::get_error_file_name(ec) << "\n";
          ␣
↪       hpx::cout << "{line}: " << hpx::get_error_line_number(ec)
                          << "\n";
             ␣
↪    hpx::cout << "{os-thread}: " << hpx::get_error_os_thread(ec)
                          << "\n";
              hpx::cout << "{thread-id}: " << std::hex
                          << hpx::get_error_thread_id(ec) << "\n";
              hpx::cout << "{thread-description}: "
              ␣
↪             << hpx::get_error_thread_description(ec) << "\n\n";
                ␣
↪hpx::cout << "{state}: " << std::hex << hpx::get_error_state(ec)
                          << "\n";
               ␣
↪  hpx::cout << "{stack-trace}: " << hpx::get_error_backtrace(ec)
```

(continues on next page)

(continued from previous page)

```
                          << "\n";
↪       hpx::cout << "{env}: " << hpx::get_error_env(ec) << "\n";
            }

            hpx::cout << std::flush;
```

For more information please refer to the documentation of hpx::get_error_what, *hpx::get_error_locality_id*, *hpx::get_error_host_name*, *hpx::get_error_process_id*, hpx::get_error_function_name, hpx::get_error_file_name, hpx::get_error_line_number, *hpx::get_error_os_thread*, *hpx::get_error_thread_id*, *hpx::get_error_thread_description*, *hpx::get_error_backtrace*, *hpx::get_error_env*, and *hpx::get_error_state*.

Lightweight error codes

Sometimes it is not desirable to collect all the ambient information about the error at the point where it happened as this might impose too much overhead for simple scenarios. In this case, *HPX* provides a lightweight error code facility that will hold the error code only. The following snippet demonstrates its use:

```
            hpx::cout␣
↪<< "Error reporting using an lightweight error code\n";

            // Create a new error_code instance.
            hpx::error_code ec(hpx::throwmode::lightweight);

            // If an␣
↪instance of an error_code is passed as the last argument while
            // invoking␣
↪the action, the function will not throw in case of an error
            // but␣
↪store the error information in this error_code instance instead.
            raise_exception_action do_it;
            do_it(hpx::find_here(), ec);

            if (ec)
            {
                // Print just the essential error information.
↪     hpx::cout << "returned error: " << ec.get_message() << "\n";

                //␣
↪Print all of the available diagnostic information as stored with
                // the exception.
                hpx::cout << "error code:" << ec.value() << "\n";
            }

            hpx::cout << std::flush;
```

All functions that retrieve other diagnostic elements from the *hpx::error_code* will fail if called with a lightweight error_code instance.

2.4.21 The *HPX* I/O-streams component

The *HPX* I/O-streams subsystem extends the standard C++ output streams `std::cout` and `std::cerr` to work in the distributed setting of an *HPX* application. All of the output streamed to `hpx::cout` will be dispatched to `std::cout` on the console *locality*. Likewise, all output generated from `hpx::cerr` will be dispatched to `std::cerr` on the console *locality*.

Note

All existing standard manipulators can be used in conjunction with `hpx::cout` and `hpx::cerr`.

In order to use either `hpx::cout` or `hpx::cerr`, application codes need to `#include <hpx/include/iostreams.hpp>`. For an example, please see the following 'Hello world' program:

```
// Including␣
↪'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to␣
↪use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Additionally, those applications need to link with the iostreams component. When using CMake this can be achieved by using the `COMPONENT_DEPENDENCIES` parameter; for instance:

```
include(HPX_AddExecutable)

add_hpx_executable(
    hello_world
    SOURCES hello_world.cpp
    COMPONENT_DEPENDENCIES iostreams
)
```

Note

The `hpx::cout` and `hpx::cerr` streams buffer all output locally until a `std::endl` or `std::flush` is encountered. That means that no output will appear on the console as long as either of these is explicitly used.

2.4.22 Supervision dispatch

The supervision dispatch component (`hpx::supervision`, built on top of the *Supervision module* module) lets a locality discover its peers, detect when one of them has gone silent, and safely stop dispatching work to a peer that has latched a terminal lifecycle event - all without every caller needing to make an authoritative, synchronous round-trip for every dispatch.

This page describes the initialization and shutdown ordering applications must follow, the one-shot nature of peer discovery, the distinction between the locally cached peer state and the registry's authoritative state, and how that distinction shows up in the two-tier admission check used by fenced dispatch. For the detailed semantics of individual lifecycle events, `check_admission`, and `dispatch_outcome` values, see *Supervision module*; this page does not repeat that reference material. For the API reference of the dispatch-specific types and functions this component introduces - `registry`, `discovery::discover_and_join`, and `dispatch_work` - see *Supervision dispatch module*.

Initialization and shutdown ordering

Supervision dispatch is brought up with a single call to *hpx::supervision::init* and torn down with a single call to *hpx::supervision::finalize*:

```
#include <hpx/supervision_dispatch.hpp>

// Blocking, one-shot startup for this locality.
hpx::supervision::init(hpx::launch::sync);

// ... application runs, dispatching fenced work to peers ...

// Cooperative, one-shot shutdown for this locality.
hpx::supervision::finalize();
```

`init()` performs, in order:

1. Creation of a local `registry` component for this locality.
2. Publication of `event::started` on the locality - *before* the component's symbol name is registered with AGAS, so that no peer can discover and join a not-yet-started locality.
3. Registration of the symbol name.
4. A single *hpx::supervision::discover_and_join* pass that joins every peer registry reachable within `discovery_timeout`. Its result is a list of `joined_discovery_result` (peer paired with the shadow id its `join()` call was assigned); peers that time out mid-pass are omitted from that list entirely rather than leaving a gap in it.

   `init()` is idempotent: calling it while already active is a no-op, and concurrent callers attach to a single in-flight initialization rather than racing to create duplicate registries. `finalize()` mirrors this ordering in reverse - it publishes `event::completed` for the local locality, unregisters the symbol name, and releases the `registry` component - and is always safe to call speculatively (e.g. during shutdown) even if `init()` was never called, since it is a no-op unless the runtime is currently active.

Applications should treat `init()`/`finalize()` as a matched pair around the portion of the program that performs supervised, fenced dispatch, and should not assume any lifecycle event is visible to peers before `init()`'s future (or synchronous call) has completed.

Calling `init()` again after it has already succeeded is a documented no-op: it returns an already-ready future without repeating any of the four steps above, and in particular does **not** re-run `discover_and_join()`. Peers that started, or otherwise became discoverable, after the first `init()` call completed are *not* retroactively added to the registry by a second call – the one-shot discovery behavior described below applies equally to repeated `init()` calls, not just the first one. To pick up such a peer, join it explicitly via `registry::join()`. Calling `init()` while a previous call is still in progress attaches to that same in-flight initialization rather than starting a second one; calling it while `finalize()` is concurrently in progress fails immediately with `hpx::error::invalid_status` rather than queuing behind it.

What is a target, and how is it introduced

A "target" is nothing more than an `hpx::id_type` - the id of any locality or component whose lifecycle should be tracked. It is not a distinct kind of object, and there is no separate handle or wrapper type: the same id you'd use to invoke an action on a component is what you pass as `target` to `publish_event()`, `check_admission()`, `dispatch_work()`, and the rest of the supervision API.

Because `dispatch_work()` resolves `target` via `hpx::colocated()` to find the locality to dispatch to, a target must also be independently resolvable by AGAS to some locality - this is a separate requirement from having recorded supervision state, and it is not something supervision dispatch itself grants. Any id obtained the ordinary way (creating a component, `hpx::find_here()`, a symbolic-name lookup, a peer's joined registry id) already satisfies this. If a target id can no longer be resolved to a locality - for instance, because the underlying component was already destroyed and unregistered - `dispatch_work()` fails when `hpx::colocated()` cannot resolve it, *before* either admission check runs; this is a distinct failure mode from `hpx::error::target_fenced` and is not something publishing `event::started` can paper over.

In practice, two kinds of ids show up as targets in this component:

- The registry id of peer localities, once joined via *`hpx::supervision::registry::join`* - these are the targets whose shadow state feeds `registry::snapshot_peers()` and local admission filtering.
- The ids of individual localities/components that fenced work is dispatched against via *hpx::supervision::dispatch_work* (`dispatch_work(target, epoch, ...)`) - these need not be peers' localities at all; any component id that has had lifecycle events published for it can be fenced.

Unlike joining a peer registry, there is no explicit "register this target" call for the underlying supervision manager. A target is introduced implicitly, purely as a side effect of publishing its first event: the supervision manager tracks targets in a map keyed by id, and a lookup miss is treated as "this target has never been seen," with an implicit current epoch of `0` and a default event of `unknown`. The lifecycle-transition validation then requires that the *first* event ever published for a target open with `started` - publishing anything else for a target with no prior recorded state is rejected as an invalid transition. Put simply:

```
// Introduces␣
↪`some_actor` as a tracked target under epoch 0. This is the
// only step required - no prior registration call exists.
```

(continues on next page)

(continued from previous page)

```
hpx::supervision::publish_
→event(some_actor, hpx::supervision::event::started, 0);

// From␣
→this point on, `some_actor` has recorded state: query_state(),
// check_
→admission(), and dispatch_work() against it now reflect that
// state rather than "unknown."
```

Before a target's first `started` publication, it has no recorded state at all: `query_state()` reports it as `unknown` rather than as any specific lifecycle stage, and `check_admission()` for an epoch-0, never-published target behaves as admitting (there is nothing latched to fence against yet). Once introduced, a target's tracked state persists on the supervision manager that owns it until either it reaches a terminal event that is superseded by a higher epoch (see "Epochs and when to change them" below), or it is explicitly forgotten via `remove_target()` - typically done by callers that know a given id will never be queried or observed again locally, e.g. after a failed registration attempt or once a peer has been evicted from the registry, to avoid accumulating unbounded per-target state.

Removing a target

hpx::supervision::remove_target is the counterpart to introducing a target: it unconditionally erases whatever supervision state is locally recorded for a target id, on a single locality.

```
// Synchronous version, target on a possibly remote locality:
hpx::supervision::remove_
→target(hpx::launch::sync, locality, target);
```

See *Supervision module* for the full semantics of `remove_target`, and *Supervision dispatch module* for this component's own API reference.

A few points worth calling out:

- **It is a forget operation, not a lifecycle event.** It erases the target's tracked state (epoch, current event, sequence number) and any observers still registered for it, without publishing an event of any kind. This is different from a target reaching a terminal event – removal discards history rather than recording an outcome.
- **It is local only.** Removal only clears state held on the given `locality` (or the calling locality, for the local-only overload). It does not touch `target`'s state on any other locality, and it does not affect AGAS registration or symbolic names for that id.
- **It is safe to call on a target with no recorded state.** This is a documented no-op rather than an error, so callers do not need to first check whether a target was ever introduced before removing it.
- **Republishing afterward reintroduces the target from scratch.** After removal, publishing `event::started` for the same id behaves exactly as if the id had never been seen before - epoch resets to whatever the new `started` publication specifies.
- **Safe to call from within the target's own observer callback.** Calling `remove_target()` on `target` from inside one of `target`'s own observer callbacks is supported and does not deadlock.

Removing a target is the natural cleanup step once it is known to be permanently done with - for example, once a peer has been evicted from the registry, or once a fenced target has reached a terminal event and will not be reincarnated under a new epoch - so that per-target state does not accumulate indefinitely over the lifetime of a long-running application.

Application-visible state machines

Applications observe two distinct, overlapping state machines.

Per-locality dispatcher lifecycle

Tracked once per locality (`dispatch_api.cpp`), driven by `init()`/ `finalize()`:

```
uninitialized␣
↪-> initializing -> active -> finalizing -> uninitialized
```

- `uninitialized`: no local registry exist.
- `initializing`: registry creation, `event::started` publication, symbol registration, and the one-shot `discover_and_join()` pass are in progress. Concurrent callers attach to the same in-flight initialization rather than racing.
- `active`: heartbeat and failure-detection background tasks are running.
- `finalizing`: background tasks are being stopped, `event::completed` is published, and the symbol name is being unregistered before component release.

  `init()/finalize()` are idempotent no-ops when already in the target state. A failure during `initializing` unregisters any names already registered and returns to `uninitialized` rather than leaving the locality stuck mid-transition.

Per-target lifecycle event

Reported by an actor about itself (`hpx::supervision::event`), tracked per epoch and mirrored into peer shadows:

```
unknown -> started -> running -> suspending -> completed
                   \-> failed
                   \-> losing_locality
```

`completed` and `failed` are terminal: once published for a target/epoch, later terminal publications for that same target/epoch are rejected as already-terminal, and publications carrying a lower epoch are rejected as stale. `losing_locality` is a non-terminal warning that the hosting locality may become unavailable.

How they interact

The dispatcher-lifecycle state machine governs whether *this locality* can participate at all. The per-target event state machine governs whether *a specific peer* remains eligible for fenced dispatch. Failure detection moves a peer's locally cached shadow toward `failed` only when a timeout on `await_terminal` coincides with an unchanged event sequence number - a timeout alone is not sufficient, since the peer may simply still be `running`. This local `failed` marking never touches the peer's own authoritative state; it only affects what this locality's client-side filtering sees, per the shadow/authoritative distinction above.

Heartbeats: distinguishing idle from dead

While a locality is `active` (see "Application-visible state machines" above), a background heartbeat task runs alongside the failure-detection loop. Its job is narrow but essential: periodically republish `event::running` against the locality, purely to keep that localty's event sequence number and timestamp advancing even when the application itself has nothing new to report.

Why this is needed

Failure detection works by calling `await_terminal()` with a timeout against each joined peer's shadow. On its own, a bare timeout on that call is ambiguous: it fires identically whether the peer has crashed, or the peer is simply alive and quietly idle – `running` is a stable state that can legitimately persist for a long time with no events published at all. Without some independent signal of liveness, failure detection would have no way to tell these two situations apart, and would either fence peers that are perfectly healthy but quiet, or fail to fence peers that have genuinely died.

The heartbeat resolves this by giving every alive peer a steady, low-cost source of forward progress – its event sequence number – independent of whatever the application is actually doing. This lets `peer_is_alive_but_silent()` compare a peer's sequence number immediately before and after an `await_terminal()` timeout:

- If the sequence number **advanced** during the timeout window, the peer's heartbeat kept running, so the peer is alive but simply not reporting a terminal event - no action is taken.
- If the sequence number **did not change**, the peer's own heartbeat task has itself gone silent, which is treated as genuine evidence of a stall, and the failure-detection loop fences the peer locally by publishing `event::failed` against its shadow (never against the peer's own, remote, authoritative state - see "Shadow state versus the authoritative registry" above).

Operational properties

- **Best-effort.** A failed heartbeat publication attempt does not stop or crash the loop; it is simply retried on the next interval.
- **Fixed interval, tied to detection timing.** The heartbeat republishes at roughly a third of the failure-detection poll timeout, so that under normal conditions several heartbeats land within any single detection window – making a missed heartbeat a meaningful signal rather than noise from timing jitter.
- **Started and stopped in lockstep with failure detection.** Both background tasks are started together, immediately after the one-shot `discover_and_join()` pass inside `init()`, and both are signaled to stop and joined together during `finalize()`, before `event::completed` is published and either symbol name is unregistered.
- **Entirely internal.** Applications do not start, stop, or configure the heartbeat directly, and do not need to publish any events themselves to keep it running – it is a side effect of calling `init()`, and requires no ongoing application action beyond staying inside the `init()/finalize()` bracket.

  In short, the heartbeat is what makes failure detection's timeout-based stall check meaningful at all: without it, a timeout by itself would not be able to distinguish "no news" from "no pulse."

  This is also why fenced dispatch depends on the heartbeat working correctly, not just on failure detection running. `check_admission()` - whether called as the caller's local, non-authoritative early-out or as the target's own authoritative re-check inside `invoke_fenced_action()` - ultimately answers "is this target still available" by consulting whatever lifecycle state has been latched for it, which for peers is only ever updated to `failed` once failure detection has genuine evidence of a stall. Without the heartbeat, that evidence would not exist: a silent-but-alive peer and a genuinely dead one would look identical to `await_terminal()`, and admission would have no reliable basis for deciding whether it is safe to keep dispatching work to that locality. In short, the heartbeat is not just an internal detail of failure detection - it is what makes the fencing decisions applications rely on throughout this page trustworthy in the first place.

One-shot discovery and staleness

The `discover_and_join()` pass performed by `init()` runs exactly once. It finds whichever peer registries are reachable *at that moment* and joins them; it does not re-run periodically, and peers that join the system later are not automatically discovered by localities that have already initialized. This has two practical implications:

- A locality's set of known peers is fixed at `init()` time (plus any peers joined explicitly afterwards via `registry::join()`). It does not grow on its own as new peers appear.
- Because failure detection (see below) only tracks peers that have actually been joined, a peer that starts too late to be discovered is invisible to both admission filtering and fencing until it is joined explicitly.

Applications that need a stable, complete peer set at some later point should join peers explicitly (`registry::join()`) rather than relying on rediscovery after `init()`.

Shadow state versus the authoritative registry

Once a peer is joined, its lifecycle state is mirrored locally into a *shadow* target owned by the joining registry - a lightweight, locally readable copy of that peer's most recently observed state, updated as lifecycle and heartbeat events arrive. This shadow state is what `registry::snapshot_peers()` and the local admission check consult.

It is important to keep two things distinct:

- **Shadow state** (local): a locally cached view of a peer's lifecycle, updated asynchronously as events are received. It can lag reality by however long it takes an event to propagate, and can go stale entirely if the peer's heartbeat has stopped but failure detection has not yet timed out.
- **Registry state** (remote, authoritative): the actual lifecycle/fencing state tracked by the peer's own supervision manager, on the peer's own locality. This is the only state that is authoritative for admission decisions.

Failure detection narrows - but does not eliminate - the gap between the two: a background loop periodically checks each joined peer's shadow for silence and marks it accordingly, but there is always a window between a peer actually going silent and that silence being locally observed.

How registries stay synchronized

The shadow-mirroring described above is not maintained by polling. It is driven entirely by event-based observer callbacks, registered once at `registry::join()` time and then firing automatically for the lifetime of the joined peer.

Registration, at join time

When `registry::join(peer_locality)` is called, the local registry does two things before returning a shadow id to the caller. A peer's identity *is* its locality since exactly one registry exists per locality.

1. **Seeds the shadow with the peer's current state.** It performs a single, synchronous `query_state()` call against `peer_locality` to read whatever epoch the peer is currently in, then publishes `event::started` for that epoch onto a freshly minted shadow id. This seed step exists so the shadow reflects the peer's state as of joining, rather than starting from `unknown` and waiting for the first subsequent event to arrive.
2. **Registers a lifecycle-event observer** on `peer_locality` (via `hpx::supervision::register_observer()`), along with an activity-transition observer (via `register_activity_observer()`, currently a no-op placeholder reserved for future use). These registrations live on the peer's own locality and are what make the subsequent synchronization automatic: no further polling or explicit refresh call from the local registry is needed.

Both registrations are made atomically with respect to concurrent `join()` calls for the same peer (a reservation is taken in `peers_` before either remote call is issued), and either observer failing to register cleanly rolls back the other, so a peer is never left half-joined.

Ongoing synchronization

From then on, every event the peer publishes for itself - including the heartbeat's periodic `event::running` republication (see "Heartbeats: distinguishing idle from dead" above) – invokes the registered lifecycle observer callback on the *peer's* locality, which in turn calls back into the joining registry to mirror that event onto the local shadow, at the same epoch it actually occurred in. No round trip is initiated by the joining side to "check in" on a peer; synchronization is entirely push-driven by whichever locality actually observes the peer's own state changing.

If the mirrored event is terminal (`completed` or `failed`), the callback additionally schedules - via `hpx::post()`, deferred rather than inline, since the callback itself does not hold the registry's lock - the peer's eviction from `peers_`. Once evicted, the peer no longer appears in `registry::snapshot_peers()`, and its observer registrations are unregistered on the peer's locality so nothing is left listening for further events from a peer that has already reached a terminal state.

What this does and does not cover

This automatic synchronization keeps the shadow up to date with whatever the peer *chooses to publish* - it is not a substitute for failure detection. A peer that stops publishing anything at all (e.g. because it crashed) generates no event, so no observer callback fires, and the shadow simply stops advancing. Detecting that silence, and deciding whether it means the peer is dead rather than merely idle, is exactly the job of the heartbeat/failure-detection pairing described earlier in this page – the observer-based synchronization described here and the polling-with-timeout failure detection described earlier are complementary, not overlapping, mechanisms.

Because `observers_` is keyed per target and holds a list rather than a single callback, this fan-out is genuinely one-to-many: if several localities have each independently joined the same peer, a single event published by that peer notifies every one of their registries in the same pass, each mirroring the event onto its own local shadow. This reach is scoped to the publishing target, however – only localities that have actually called `join()` against that specific peer are registered as observers and receive its events. A locality that has not joined a given peer is not notified when that peer publishes, regardless of whether it participates in supervision dispatch generally.

Client-side filtering versus fenced-dispatch admission

This shadow/authoritative distinction is exactly why fenced dispatch performs *two* admission checks rather than one:

- **Client-side filtering** (`check_admission()` called directly by the caller, or peer filtering based on `registry::snapshot_peers()`) consults only the locally cached shadow state. It is fast and involves no remote round-trip, but its answer can be stale: it may say a peer is admitted when the peer has, in fact, already latched a terminal event that just hasn't propagated back yet. This check is an optimization - a cheap way to avoid dispatching work that is *already known locally* to be pointless - and must never be treated as authoritative.
- **Fenced-dispatch admission** (the re-check performed inside `invoke_fenced_action()`, once the dispatched action has actually reached the target's own locality via `hpx::colocated`) runs on the same locality/thread that owns the target's authoritative supervision state, with no suspension point between the check

and the action invocation that follows it. This is the check that actually decides whether the wrapped action runs, and it is what closes the race between a stale client-side "admitted" result and a peer that has since gone terminal.

In short: use client-side filtering to avoid *obviously* wasted dispatches; rely only on the fenced-dispatch outcome to know whether work actually ran.

Epochs and when to change them

Every lifecycle event and every fenced dispatch is scoped to an epoch (`std::uint64_t`, defaulting to `0`). The epoch is what lets a target be "un-fenced" and reused after it has latched a terminal event, instead of being permanently unusable once it completes or fails once.

A target's epoch only ever increases, and publications are compared against whatever epoch is currently in effect for that target:

- A publication for the **same** epoch as the target's current one is normal progression (`started` -> `running` -> ... -> a terminal event), subject to the terminal/already-terminal rule described above.
- A publication for a **lower** epoch than the target's current one is rejected as stale (`publish_result::stale_epoch`) and has no effect - this guards against a delayed or reordered event from an earlier generation of the target clobbering newer state.
- A publication for a **higher** epoch than the target's current one resets the target: it becomes the new current epoch, the event sequence number resets, and any previously latched terminal event (`completed`/ `failed`) under the old epoch no longer fences new dispatches. This is the only way to make a target eligible for fenced dispatch again after it has gone terminal.

The same epoch value is consulted end-to-end: `check_admission(target, epoch)` compares the *epoch you pass in* against the target's current epoch, not just whether the target is terminal in some absolute sense. This is why both `dispatch_work()`'s local check and `invoke_fenced_action()`'s remote re-check take an explicit `epoch` argument rather than operating on "the" state of the target.

When to keep the epoch the same

Use the same epoch value across all fenced dispatches that belong to the same logical run/incarnation of the target - e.g. repeated or retried calls against a target that is still expected to be `started`/`running` under the epoch it was initialized with. Fencing is only meaningful when related dispatches share an epoch: if a target has already latched `failed` for epoch `N`, every further dispatch under epoch `N` is correctly rejected, which is the intended behavior - it stops work from continuing to target something that has already terminated in this generation.

When to bump the epoch

Bump to a new, higher epoch when you are intentionally starting a new generation of the target and want prior terminal state to stop fencing new work - typically when a target is restarted/reincarnated after failing or completing, and you want dispatch to resume against the restarted instance rather than remain permanently fenced by the old generation's terminal event. Concretely: publish the target's own `event::started` under the new epoch as part of bringing the restarted instance up, then use that same, higher epoch value for subsequent dispatches and admission checks against it.

Do not reuse an old epoch value after bumping, and do not bump the epoch merely to "clear" a fence for the *same* running instance - if the target has not actually restarted, admission is correctly rejecting dispatch because the target is genuinely terminal, and forcing an epoch bump only defeats that protection rather than fixing the underlying condition.

How fenced work is invoked

`hpx::supervision::dispatch_work<action_type>(target, epoch, action, args...)` is the entry point callers use. It performs two distinct steps, on two different localities:

1. **Local, non-authoritative early-out (caller's locality).** `dispatch_work()` first calls `check_admission(target, epoch)` against the caller's own locally cached shadow state. If this reports `dispatch_outcome::rejected_fenced`, `dispatch_work()` returns an already-exceptional future carrying `hpx::error::target_fenced` immediately - no parcel is ever sent, and the wrapped action is never invoked. This is purely an optimization to avoid a wasted round trip; it is not authoritative, since the shadow state it consults can be stale (see the sections above).
2. **Colocated dispatch and authoritative re-check (target's locality).** If the local check does not reject, `dispatch_work()` wraps the caller's action in a generated `fenced_action` and dispatches it via `hpx::async` to `hpx::colocated(target)` - i.e. it runs on the same locality that hosts `target` and owns its authoritative supervision state. The action body that actually runs there is `invoke_fenced_action()`, which performs a *second* `check_admission(target, epoch)` call. Because this call executes on the same locality/thread that owns the target's supervision state, with no suspension point before the wrapped action runs immediately afterward (via `hpx::sync`, invoked directly/locally with no further parcel hop), this second check is authoritative. If it also reports `rejected_fenced` - meaning the target latched a terminal event for this epoch sometime between the caller's stale check and this point - `invoke_fenced_action()` throws `hpx::error::target_fenced` instead of invoking the action.

Note that "dispatched to the target's locality" does not imply a network round-trip: `hpx::colocated(target)` resolves to whichever locality actually hosts `target`, including the invoking locality itself when `target` happens to be local. In that case no parcel is sent, but `invoke_fenced_action()` - and, if admitted, the wrapped action inside it - still each run on a newly spawned HPX thread rather than inline on the calling thread, exactly as an unfenced `hpx::async<Action>(target, args...)` call behaves when `target` is local: it schedules a new thread rather than invoking the action synchronously in place. The one exception, on both sides, is an action explicitly declared as a `direct_action`, which HPX is permitted to invoke inline when the target is local; `fenced_action` itself is an ordinary action, and the wrapped user `Action` follows whatever declaration the caller gave it. Either way, fenced dispatch adds only the two-tier admission check described above - it does not change whether or where the action is scheduled to run relative to unfenced dispatch.

Both the local early-out and the remote re-check surface failure as the same exception type/message shape (`hpx::error::target_fenced`), so callers handle a single error regardless of which side detected the fence:

```
caller locality                         target locality
----------------                        ---------------
dispatch_work(action, target, epoch, args...)
  check_admission(target, epoch)   <-- reads local shadow (non-authoritative)
    rejected -> exceptional future, done (no dispatch sent)
    admitted -> hpx::async(fenced_action, hpx::colocated(target), ...)
                                    |
                                    v
                                        invoke_fenced_action(action, target, epoch)
                                          check_admission(target, epoch)  <-- authoritative,
                                                                              same locality/thread
                                            rejected -> throw target_fenced
                                            admitted -> hpx::sync(action, target, ...)
```

Only `target` (not `epoch`) is forwarded into the wrapped action's own argument list; the epoch is fencing metadata consumed entirely by the dispatch machinery. A convenience overload of `dispatch_work()` accepts an action instance directly rather than only an action type, but follows the identical two-check flow described above.

Relationship to unfenced dispatch

From the caller's point of view, converting an unfenced dispatch into a fenced one requires exactly two changes to the call site:

```
// Unfenced:
hpx::future<result_type> f = hpx::async<Action>(target, args...);

// Fenced:
hpx::future<result_type> f =
    hpx::supervision::dispatch_work<Action>(target, epoch, args...);
```

1. Replace the call to `hpx::async<Action>` with `hpx::supervision::dispatch_work<Action>`.
2. Insert the fencing `epoch` as the second argument, ahead of the action's own arguments (`args...` is otherwise unchanged and is forwarded to `Action` verbatim).

Both a template-argument form and an instance-argument form are available for `dispatch_work()`, mirroring the two ways `hpx::async` can be called:

```
// Action specified as an explicit template argument (as above):
hpx::future<result_type> f =
    hpx::supervision::dispatch_work<Action>(target, epoch, args...);

// Convenience overload: action passed as an instance, deduced instead of
// spelled out explicitly. Note the action instance comes *first*, ahead
// of `target` and `epoch`.
hpx::future<result_type> f =
    hpx::supervision::dispatch_work(Action(), target, epoch, args...);
```

The instance-argument overload is a thin wrapper that simply forwards to the template-argument overload above; the two are otherwise identical in behavior (same two-check admission flow, same exception on fencing, same argument forwarding to `Action`). It exists purely so that call sites already holding an action instance - rather than naming the action type directly – don't need an extra step to obtain one, the same convenience `hpx::async` itself offers by accepting either an action type or an action instance.

Everything else - `target`, the returned `hpx::future<result_type>`, and how the caller consumes it (`.get()`, continuations, etc.) - stays the same. The only additional caller-side responsibility is handling `hpx::error::target_fenced` on that future (see below), since a fenced dispatch never invokes `Action` at all, whereas an unfenced `hpx::async<Action>` call has no equivalent rejection path.

Observing whether an action was fenced

From the caller's point of view, `dispatch_work()` always returns an `hpx::future`. Whether the fence was detected locally (early-out, no dispatch sent) or remotely (authoritative re-check on the target's own locality), the future becomes exceptional in exactly the same way, so callers do not need to special-case which side caught it:

```
hpx::future<result_type> f =
    hpx::supervision::dispatch_work(action, target, epoch, args...);

try
{
    result_type result = f.get();
    // Admitted on both checks; action ran and produced `result`.
}
catch (hpx::exception const& e)
{
    if (e.get_error() == hpx::error::target_fenced)
    {
        // Fenced - either the caller's local admission check rejected
        // it before any dispatch was sent, or the target's own
        // authoritative re-check rejected it just before invocation.
```

(continues on next page)

(continued from previous page)

```
        // The wrapped action was NOT invoked in either case.
    }
    else
    {
↪   throw;    // some other failure (e.g. transport, target action
                  // itself threw)
    }
}
```

Two points worth calling out explicitly:

- `e.get_error() == hpx::error::target_fenced` is the single, reliable signal that an action was fenced. Matching on the exception's `what()` text is unnecessary and discouraged, since the message wording is not part of the stable contract; only the error code is.
- A fenced result and a "the action itself threw" result are both surfaced through the same future/exception mechanism, so callers must check `get_error()` to distinguish "not invoked because fenced" from "invoked, but failed." There is no separate return value, flag, or callback that reports fencing independently of the future's exceptional state.

  Because `f.get()` throws synchronously the moment either check rejects, a caller waiting with a timeout (see below) sees ready-with-exception rather than ready-with-result if either side fenced the dispatch before the timeout elapsed.

Worked examples

Fencing a silent peer

```
#include <hpx/supervision_dispatch.hpp>

hpx::supervision::registry local_registry(hpx::find_here());

hpx::supervision::joined_peer const peer = local_registry.join(
    hpx::launch::sync, hpx::find_here());

// ... time passes; the peer's heartbeat stops ...

// Client-
↪side filtering: cheap, but only as fresh as the last observed
// heartbeat/lifecycle event mirrored onto `shadow`.
for (auto
↪const& peer : local_registry.snapshot_peers(hpx::launch::sync))
{
    if (peer.state == hpx::supervision::lifecycle_state::failed)
    {
↪    // Skip obviously-dead peers before even attempting dispatch.
        continue;
    }
    //
```

(continues on next page)

(continued from previous page)

```
↪ Attempt fenced dispatch anyway; the target-side re-check inside
    // invoke_
↪fenced_action() is authoritative and will reject the action
    // with␣
↪hpx::error::target_fenced if the peer has latched a terminal
    // event we haven't observed locally yet.
}
```

Waiting on a dispatch outcome with a timeout

```
#include <hpx/async_combinators/wait_all_for.hpp>
#include <hpx/supervision_dispatch.hpp>

hpx::future<result_type> f =
   ␣
↪hpx::supervision::dispatch_work(target, epoch, action, args...);

if (hpx::wait_all_for(std::chrono::seconds(5), f) ==
    hpx::future_status::ready)
{
    try
    {
        result_type result = f.get();
    }
    catch (hpx::exception const& e)
    {
        if (e.get_error() == hpx::error::target_fenced)
        {
    ␣
↪           // Authoritative rejection: the target latched a terminal
            // event for this epoch before the action could run.
        }
    }
}
else
{
    //
↪ Dispatch did not complete within the timeout; the target may be
    // slow, unreachable, or the shadow state used for client-side
    // filtering may be stale.
}
```

Querying state and publishing events through a handle

The handle returned by `init()` also doubles as the argument to a small family of convenience overloads of `query_state()`/`publish_event()` that resolve locality and target automatically, instead of requiring the caller to extract `handle.get_id()` and `hpx::find_here()` manually:

```
#include <hpx/supervision_dispatch.hpp>

hpx::supervision::registry const handle =
    hpx::supervision::init(hpx::launch::sync);

// Recover the epoch init() started this handle's locality at, for use
// with dispatch_work()/publish_event() later on.
std::uint64_t const epoch =
    hpx::supervision::query_state(hpx::launch::sync, handle).epoch;

// ... later, e.g. once this locality's own supervised work completes ...
hpx::supervision::publish_event(
    hpx::launch::sync,
    handle, hpx::supervision::event::completed, epoch);
```

Querying a peer's state after joining it follows the same pattern, using a `discovered_peer` in place of an explicit locality/target pair:

```
for (auto const& peer :
    hpx::supervision::discover_and_join(handle))
{
    hpx::supervision::lifecycle_state const peer_state =
        hpx::supervision::query_state(hpx::launch::sync, handle, peer);
    // `handle` is only needed here for overload resolution; `peer`
    // alone carries the locality/target this call actually queries.
}
```

There is no peer-publishing overload: a locality only ever publishes lifecycle events it self, never on behalf of a peer's.

A worked example combining this with a supervised worker loop - covering when to publish `started`/`running`/a terminal event for a worker's own locality, and how a supervisor queries peer worker state through the handle above - is available in `components/supervision_dispatch/examples/plain_worker.cpp`.

See *Supervision module* for the full semantics of `check_admission`, `dispatch_outcome`, and the individual lifecycle events referenced above, and *Supervision dispatch module* for the API reference of this component's own types and functions (`registry`, `discovery`, and `dispatch_work`).

2.4.23 Troubleshooting

Common issues

This section contains commonly encountered problems when compiling or using HPX.

See also the closed issues on GitHub[206] to find out how other people resolved a similar problem. If nothing of that works, you can also open a new issue on GitHub[207] or contact us using one the options found in Support for deploying and using HPX[208].

`hpx::iostreams_component" target not found`

You may see a CMake[209] error message that looks a bit like this:

```
error: `hpx::iostreams_component`` target not found
```

Simply ensure that *HPX* is installed with `HPX_WITH_DISTRIBUTED_RUNTIME=ON` to prevent encountering such error(s). This is required if you want to use `hpx::cout`.

`Undefined reference to hpx::cout`

You may see a linker error message that looks a bit like this:

```
hello_world.cpp:(.text+0x5aa): undefined reference to `hpx::cout'
```

This usually happens if you are trying to use *HPX* iostreams functionality such as `hpx::cout` but are not linking against it. The iostreams functionality is not part of the core *HPX* library, and must be linked to explicitly. Typically this can be solved by adding `COMPONENT_DEPENDENCIES iostreams` to a call to `add_hpx_library/add_hpx_executable/hpx_setup_target` if using CMake[210]. See *Creating HPX projects* for more details.

`Build fails with ASIO error`

You may see an error message that looks a bit like this:

```
Cannot open include file asio/io_context.hpp
```

This can be resolved by using `-DHPX_WITH_FETCH_ASIO=ON` to the cmake command line.

See also the corresponding closed Issue #5404[211] for more information.

[206] https://github.com/TheHPXProject/hpx/issues?q=is%3Aissue+is%3Aclosed
[207] https://github.com/TheHPXProject/hpx/issues
[208] https://github.com/TheHPXProject/hpx/blob/master/.github/SUPPORT.md
[209] https://www.cmake.org
[210] https://www.cmake.org
[211] https://github.com/TheHPXProject/hpx/issues/5404

Build fails with TCMalloc error

You may see an error message that looks a bit like this:

```
Could NOT␣
↪find TCMalloc (missing: Tcmalloc_LIBRARY Tcmalloc_INCLUDE_DIR)
ERROR:␣
↪HPX_WITH_MALLOC was set to tcmalloc, but tcmalloc could not be
found.  Valid␣
↪options for HPX_WITH_MALLOC are: system, tcmalloc, jemalloc,
mimalloc, tbbmalloc, and custom
```

This can be resolved either by defining `HPX_WITH_MALLOC=system` or by installing TC-Malloc. This error occurs when users don't specify an option for `HPX_WITH_MALLOC`; in that case, *HPX* will be looking `tcmalloc`, which is the default value.

Useful suggestions

Reducing compilation time

If you want to significantly reduce compilation time, you can just use the local part of *HPX* for parallelism by disabling the distributed functionality. Moreover, you can avoid compiling examples. These can be done with the following flags:

```
-DHPX_WITH_NETWORKING=OFF
-DHPX_WITH_DISTRIBUTED_RUNTIME=OFF
-DHPX_WITH_EXAMPLES=OFF
-DHPX_WITH_TESTS=OFF
```

Linking *HPX* to your application

If you want to avoid installing and linking *HPX*, you can just build *HPX* and then use the following flag on your *HPX* application CMake configuration:

```
-DHPX_DIR=<build_dir>/lib/cmake/HPX
```

Note

For this to work you need not to specify `-DCMAKE_INSTALL_PREFIX` when building *HPX*.

HPX-application build type conformance

Your application's build type should align with the HPX build type. For example, if you specified `-DCMAKE_BUILD_TYPE=Debug` during the *HPX* compilation, then your application needs to be compiled with the same flag. We recommend keeping a separate build folder for different build types and just point accordingly to the type you want by using `-DHPX_DIR=<build_dir>/lib/cmake/HPX`.

2.5 Terminology

This section gives definitions for some of the terms used throughout the *HPX* documentation and source code.

Locality
A locality in *HPX* describes a synchronous domain of execution, or the domain of bounded upper response time. This normally is just a single node in a cluster or a NUMA domain in a SMP machine.

Active Global Address Space
AGAS
HPX incorporates a global address space. Any executing thread can access any object within the domain of the parallel application with the caveat that it must have appropriate access privileges. The model does not assume that global addresses are cache coherent; all loads and stores will deal directly with the site of the target object. All global addresses within a Synchronous Domain are assumed to be cache coherent for those processor cores that incorporate transparent caches. The Active Global Address Space used by *HPX* differs from research PGAS[212] models. Partitioned Global Address Space is passive in their means of address translation. Copy semantics, distributed compound operations, and affinity relationships are some of the global functionality supported by AGAS.

Process
The concept of the "process" in *HPX* is extended beyond that of either sequential execution or communicating sequential processes. While the notion of process suggests action (as do "function" or "subroutine") it has a further responsibility of context, that is, the logical container of program state. It is this aspect of operation that process is employed in *HPX*. Furthermore, referring to "parallel processes" in *HPX* designates the presence of parallelism within the context of a given process, as well as the coarse grained parallelism achieved through concurrency of multiple processes of an executing user job. *HPX* processes provide a hierarchical name space within the framework of the active global address space and support multiple means of internal state access from external sources.

Parcel
The Parcel is a component in *HPX* that communicates data, invokes an action at a distance, and distributes flow-control through the migration of continuations. Parcels bridge the gap of asynchrony between synchronous domains while maintaining symmetry of semantics between local and global execution. Parcels enable message-driven computation and may be seen as a form of "active messages". Other important forms of message-driven computation predating active messages include dataflow tokens[213], the J-machine's[214] support for remote method instantiation, and at the coarse grained

[212] https://www.pgas.org/
[213] http://en.wikipedia.org/wiki/Dataflow_architecture
[214] http://en.wikipedia.org/wiki/J%E2%80%93Machine

variations of Unix remote procedure calls, among others. This enables work to be moved to the data as well as performing the more common action of bringing data to the work. A parcel can cause actions to occur remotely and asynchronously, among which are the creation of threads at different system nodes or synchronous domains.

Local Control Object
Lightweight Control Object
LCO

A local control object (sometimes called a lightweight control object) is a general term for the synchronization mechanisms used in *HPX*. Any object implementing a certain concept can be seen as an LCO. This concepts encapsulates the ability to be triggered by one or more events which when taking the object into a predefined state will cause a thread to be executed. This could either create a new thread or resume an existing thread.

The LCO is a family of synchronization functions potentially representing many classes of synchronization constructs, each with many possible variations and multiple instances. The LCO is sufficiently general that it can subsume the functionality of conventional synchronization primitives such as spinlocks, mutexes, semaphores, and global barriers. However due to the rich concept an LCO can represent powerful synchronization and control functionality not widely employed, such as dataflow and futures (among others), which open up enormous opportunities for rich diversity of distributed control and operation.

See lcos for more details on how to use LCOs in *HPX*.

Action

An action is a function that can be invoked remotely. In *HPX* a plain function can be made into an action using a macro. See applying_actions for details on how to use actions in *HPX*.

Component

A component is a C++ object which can be accessed remotely. A component can also contain member functions which can be invoked remotely. These are referred to as component actions. See *Writing components* for details on how to use components in *HPX*.

2.6 Why *HPX*?

Current advances in high performance computing (HPC) continue to suffer from the issues plaguing parallel computation. These issues include, but are not limited to, ease of programming, inability to handle dynamically changing workloads, scalability, and efficient utilization of system resources. Emerging technological trends such as multi-core processors further highlight limitations of existing parallel computation models. To mitigate the aforementioned problems, it is necessary to rethink the approach to parallelization models. ParalleX contains mechanisms such as multi-threading, *parcels*, *global name space* support, percolation and *local control object*s (*LCO*). By design, ParalleX overcomes limitations of current models of parallelism by alleviating contention, latency, overhead and starvation. With ParalleX, it is further possible to increase performance by at least an order of magnitude on challenging parallel algorithms, e.g., dynamic directed graph algorithms and adaptive mesh refinement methods for astrophysics. An additional benefit of ParalleX is fine-grained control of power usage, enabling reductions in power consumption.

2.6.1 ParalleX—a new execution model for future architectures

ParalleX is a new parallel execution model that offers an alternative to the conventional computation models, such as message passing. ParalleX distinguishes itself by:

- Split-phase transaction model
- Message-driven
- Distributed shared memory (not cache coherent)
- Multi-threaded
- Futures synchronization
- *Local Control Object*s (*LCO*s)
- Synchronization for anonymous producer-consumer scenarios
- Percolation (pre-staging of task data)

The ParalleX model is intrinsically latency hiding, delivering an abundance of variable-grained parallelism within a hierarchical namespace environment. The goal of this innovative strategy is to enable future systems delivering very high efficiency, increased scalability and ease of programming. ParalleX can contribute to significant improvements in the design of all levels of computing systems and their usage from application algorithms and their programming languages to system architecture and hardware design together with their supporting compilers and operating system software.

2.6.2 What is *HPX*?

High Performance ParalleX (*HPX*) is the first runtime system implementation of the ParalleX execution model. The *HPX* runtime software package is a modular, feature-complete, and performance-oriented representation of the ParalleX execution model targeted at conventional parallel computing architectures, such as SMP nodes and commodity clusters. It is academically developed and freely available under an open source license. We provide *HPX* to the community for experimentation and application to achieve high efficiency and scalability for dynamic adaptive and irregular computational problems. *HPX* is a C++ library that supports a set of critical mechanisms for dynamic adaptive resource management and lightweight task scheduling within the context of a global address space. It is solidly based on many years of experience in writing highly parallel applications for HPC systems.

The two-decade success of the communicating sequential processes (CSP) execution model and its message passing interface (MPI) programming model have been seriously eroded by challenges of power, processor core complexity, multi-core sockets, and heterogeneous structures of GPUs. Both efficiency and scalability for some current (strong scaled) applications and future Exascale applications demand new techniques to expose new sources of algorithm parallelism and exploit unused resources through adaptive use of runtime information.

The ParalleX execution model replaces CSP to provide a new computing paradigm embodying the governing principles for organizing and conducting highly efficient scalable computations greatly exceeding the capabilities of today's problems. *HPX* is the first practical, reliable, and performance-oriented runtime system incorporating the principal concepts of the ParalleX model publicly provided in open source release form.

HPX is designed by the STE||AR[215] Group (**S**ystems **T**echnology, **E**mergent Para**ll**elism, and **A**lgorithm **R**esearch) at Louisiana State University (LSU)[216]'s Center for Computation and Technology (CCT)[217] to enable developers to exploit the full processing power of many-core systems with an unprecedented degree of parallelism. STE||AR[218] is a research group focusing on system software solutions and scientific application development for hybrid and many-core hardware architectures.

For more information about the STE||AR[219] Group, see *People*.

2.6.3 What makes our systems slow?

Estimates say that we currently run our computers at well below 100% efficiency. The theoretical peak performance (usually measured in FLOPS[220]—floating point operations per second) is much higher than any practical peak performance reached by any application. This is particularly true for highly parallel hardware. The more hardware parallelism we provide to an application, the better the application must scale in order to efficiently use all the resources of the machine. Roughly speaking, we distinguish two forms of scalability: strong scaling (see Amdahl's Law[221]) and weak scaling (see Gustafson's Law[222]). Strong scaling is defined as how the solution time varies with the number of processors for a fixed **total** problem size. It gives an estimate of how much faster we can solve a particular problem by throwing more resources at it. Weak scaling is defined as how the solution time varies with the number of processors for a fixed problem size **per processor**. In other words, it defines how much more data can we process by using more hardware resources.

In order to utilize as much hardware parallelism as possible an application must exhibit excellent strong and weak scaling characteristics, which requires a high percentage of work executed in parallel, i.e., using multiple threads of execution. Optimally, if you execute an application on a hardware resource with N processors it either runs N times faster or it can handle N times more data. Both cases imply 100% of the work is executed on all available processors in parallel. However, this is just a theoretical limit. Unfortunately, there are more things that limit scalability, mostly inherent to the hardware architectures and the programming models we use. We break these limitations into four fundamental factors that make our systems *SLOW*:

- **S**tarvation occurs when there is insufficient concurrent work available to maintain high utilization of all resources.
- **L**atencies are imposed by the time-distance delay intrinsic to accessing remote resources and services.
- **O**verhead is work required for the management of parallel actions and resources on the critical execution path, which is not necessary in a sequential variant.
- **W**aiting for contention resolution is the delay due to the lack of availability of oversubscribed shared resources.

Each of those four factors manifests itself in multiple and different ways; each of the hardware architectures and programming models expose specific forms. However, the

[215] https://stellar-group.org

[217] https://www.cct.lsu.edu
[218] https://stellar-group.org
[219] https://stellar-group.org
[220] http://en.wikipedia.org/wiki/FLOPS
[221] http://en.wikipedia.org/wiki/Amdahl%27s_law
[222] http://en.wikipedia.org/wiki/Gustafson%27s_law

interesting part is that all of them are limiting the scalability of applications no matter what part of the hardware jungle we look at. Hand-helds, PCs, supercomputers, or the cloud, all suffer from the reign of the 4 horsemen: **S**tarvation, **L**atency, **O**verhead, and **C**ontention. This realization is very important as it allows us to derive the criteria for solutions to the scalability problem from first principles, and it allows us to focus our analysis on very concrete patterns and measurable metrics. Moreover, any derived results will be applicable to a wide variety of targets.

2.6.4 Technology demands new response

Today's computer systems are designed based on the initial ideas of John von Neumann[223], as published back in 1945, and later extended by the Harvard architecture[224]. These ideas form the foundation, the execution model, of computer systems we use currently. However, a new response is required in the light of the demands created by today's technology.

So, what are the overarching objectives for designing systems allowing for applications to scale as they should? In our opinion, the main objectives are:

- Performance: as previously mentioned, scalability and efficiency are the main criteria people are interested in.
- Fault tolerance: the low expected mean time between failures (MTBF[225]) of future systems requires embracing faults, not trying to avoid them.
- Power: minimizing energy consumption is a must as it is one of the major cost factors today, and will continue to rise in the future.
- Generality: any system should be usable for a broad set of use cases.
- Programmability: for programmer this is a very important objective, ensuring long term platform stability and portability.

What needs to be done to meet those objectives, to make applications scale better on tomorrow's architectures? Well, the answer is almost obvious: we need to devise a new execution model—a set of governing principles for the holistic design of future systems—targeted at minimizing the effect of the outlined **SLOW** factors. Everything we create for future systems, every design decision we make, every criteria we apply, have to be validated against this single, uniform metric. This includes changes in the hardware architecture we prevalently use today, and it certainly involves new ways of writing software, starting from the operating system, runtime system, compilers, and at the application level. However, the key point is that all those layers have to be co-designed; they are interdependent and cannot be seen as separate facets. The systems we have today have been evolving for over 50 years now. All layers function in a certain way, relying on the other layers to do so. But we do not have the time to wait another 50 years for a new coherent system to evolve. The new paradigms are needed now—therefore, co-design is the key.

[225] http://en.wikipedia.org/wiki/Mean_time_between_failures

2.6.5 Governing principles applied while developing *HPX*

As it turn out, we do not have to start from scratch. Not everything has to be invented and designed anew. Many of the ideas needed to combat the 4 horsemen already exist, many for more than 30 years. All it takes is to gather them into a coherent approach. We'll highlight some of the derived principles we think to be crucial for defeating **SLOW**. Some of those are focused on high-performance computing, others are more general.

Focus on latency hiding instead of latency avoidance

It is impossible to design a system exposing zero latencies. In an effort to come as close as possible to this goal many optimizations are mainly targeted towards minimizing latencies. Examples for this can be seen everywhere, such as low latency network technologies like InfiniBand[226], caching memory hierarchies in all modern processors, the constant optimization of existing MPI[227] implementations to reduce related latencies, or the data transfer latencies intrinsic to the way we use GPGPUs[228] today. It is important to note that existing latencies are often tightly related to some resource having to wait for the operation to be completed. At the same time it would be perfectly fine to do some other, unrelated work in the meantime, allowing the system to hide the latencies by filling the idle-time with useful work. Modern systems already employ similar techniques (pipelined instruction execution in the processor cores, asynchronous input/output operations, and many more). What we propose is to go beyond anything we know today and to make latency hiding an intrinsic concept of the operation of the whole system stack.

Embrace fine-grained parallelism instead of heavyweight threads

If we plan to hide latencies even for very short operations, such as fetching the contents of a memory cell from main memory (if it is not already cached), we need to have very lightweight threads with extremely short context switching times, optimally executable within one cycle. Granted, for mainstream architectures, this is not possible today (even if we already have special machines supporting this mode of operation, such as the Cray XMT[229]). For conventional systems, however, the smaller the overhead of a context switch and the finer the granularity of the threading system, the better will be the overall system utilization and its efficiency. For today's architectures we already see a flurry of libraries providing exactly this type of functionality: non-pre-emptive, task-queue based parallelization solutions, such as Intel Threading Building Blocks (TBB)[230], Microsoft Parallel Patterns Library (PPL)[231], Cilk++[232], and many others. The possibility to suspend a current task if some preconditions for its execution are not met (such as waiting for I/O or the result of a different task), seamlessly switching to any other task which can continue, and to reschedule the initial task after the required result has been calculated, which makes the implementation of latency hiding almost trivial.

Rediscover constraint-based synchronization to replace global barriers

The code we write today is riddled with implicit (and explicit) global barriers. By "global barriers," we mean the synchronization of the control flow between several (very often all) threads (when using OpenMP[233]) or processes (MPI[234]). For instance, an implicit global barrier is inserted after each loop parallelized using OpenMP[235] as the system synchronizes the threads used to execute the different iterations in parallel. In MPI[236] each of the communication steps imposes an explicit barrier onto the execution flow as (often all) nodes have to be synchronized. Each of those barriers is like the eye of a needle the overall execution is forced to be squeezed through. Even minimal fluctuations in the execution times of the parallel threads (jobs) causes them to wait. Additionally, it is often only one of the executing threads that performs the actual reduce operation, which further impedes parallelism. A closer analysis of a couple of key algorithms used in science applications reveals that these global barriers are not always necessary. In many cases it is sufficient to synchronize a small subset of the threads. Any operation should proceed whenever the preconditions for its execution are met, and only those. Usually there is no need to wait for iterations of a loop to finish before you can continue calculating other things; all you need is to complete the iterations that produce the required results for the next operation. Good bye global barriers, hello constraint based synchronization! People have been trying to build this type of computing (and even computers) since the 1970s. The theory behind what they did is based on ideas around static and dynamic dataflow. There are certain attempts today to get back to those ideas and to incorporate them with modern architectures. For instance, a lot of work is being done in the area of constructing dataflow-oriented execution trees. Our results show that employing dataflow techniques in combination with the other ideas, as outlined herein, considerably improves scalability for many problems.

Adaptive locality control instead of static data distribution

While this principle seems to be a given for single desktop or laptop computers (the operating system is your friend), it is everything but ubiquitous on modern supercomputers, which are usually built from a large number of separate nodes (i.e., Beowulf clusters), tightly interconnected by a high-bandwidth, low-latency network. Today's prevalent programming model for those is MPI, which does not directly help with proper data distribution, leaving it to the programmer to decompose the data to all of the nodes the application is running on. There are a couple of specialized languages and programming environments based on PGAS[237] (Partitioned Global Address Space) designed to overcome this limitation, such as Chapel[238], X10[239], UPC[240], or Fortress[241]. However, all systems based on PGAS rely on static data distribution. This works fine as long as this static data distribution does not result in heterogeneous workload distributions or other resource utilization imbalances. In a distributed system these imbalances can be mitigated by migrating part of the application data to different localities (nodes). The only framework supporting (limited) migration today is Charm++[242]. The first attempts towards solving related problem go back decades as well, a good example is the Linda coordination language[243]. Nevertheless, none of the other mentioned systems support data migration today, which forces the users to either rely on static data distribution and live with the related performance hits or to implement everything themselves, which is very tedious and difficult. We believe that the only viable way to flexibly support dynamic and adaptive *locality* control is to provide a global, uniform address space to the applications, even on distributed systems.

Prefer moving work to the data over moving data to the work

For the best performance it seems obvious to minimize the amount of bytes transferred from one part of the system to another. This is true on all levels. At the lowest level we try to take advantage of processor memory caches, thus, minimizing memory latencies. Similarly, we try to amortize the data transfer time to and from GPGPUs[244] as much as possible. At high levels we try to minimize data transfer between different nodes of a cluster or between different virtual machines on the cloud. Our experience (well, it's almost common wisdom) shows that the amount of bytes necessary to encode a certain operation is very often much smaller than the amount of bytes encoding the data the operation is performed upon. Nevertheless, we still often transfer the data to a particular place where we execute the operation just to bring the data back to where it came from afterwards. As an example let's look at the way we usually write our applications for clusters using MPI. This programming model is all about data transfer between nodes. MPI is the prevalent programming model for clusters, and it is fairly straightforward to understand and to use. Therefore, we often write applications in a way that accommodates this model, centered around data transfer. These applications usually work well for smaller problem sizes and for regular data structures. The larger the amount of data we have to churn and the more irregular the problem domain becomes, the worse the overall machine utilization and the (strong) scaling characteristics become. While it is not impossible to implement more dynamic, data driven, and asynchronous applications using MPI, it is somewhat difficult to do so. At the same time, if we look at applications that prefer to execute the code close to the *locality* where the data was placed, i.e., utilizing active messages (for instance based on Charm++[245]), we see better asynchrony, simpler application codes, and improved scaling.

Favor message driven computation over message passing

Today's prevalently used programming model on parallel (multi-node) systems is MPI. It is based on message passing, as the name implies, which means that the receiver has to be aware of a message about to come in. Both codes, the sender and the receiver, have to synchronize in order to perform the communication step. Even the newer, asynchronous interfaces require explicitly coding the algorithms around the required communication scheme. As a result, everything but the most trivial MPI applications spends a considerable amount of time waiting for incoming messages, thus, causing starvation and latencies to impede full resource utilization. The more complex and more dynamic the data structures and algorithms become, the larger the adverse effects. The community discovered message-driven and data-driven methods of implementing algorithms a long time ago, and systems such as Charm++[246] have already integrated active messages demonstrating the validity of the concept. Message-driven computation allows for sending messages without requiring the receiver to actively wait for them. Any incoming message is handled asynchronously and triggers the encoded action by passing along arguments and—possibly—continuations. *HPX* combines this scheme with work-queue based scheduling as described above, which allows the system to almost completely overlap any communication with useful work, thereby minimizing latencies.

2.8 Overview

HPX is organized into different sub-libraries and those in turn into modules. The libraries and modules are independent, with clear dependencies and no cycles. As an end-user, the use of these libraries is completely transparent. If you use e.g. `add_hpx_executable` to create a target in your project you will automatically get all modules as dependencies. See below for a list of the available libraries and modules. Currently these are nothing more than an internal grouping and do not affect usage. They cannot be consumed individually at the moment.

> **Note**
>
> There is a dependency report that displays useful information about the structure of the code. It is available for each commit at *HPX* Dependency report.

2.8.1 Core modules

affinity

The affinity module contains helper functionality for mapping worker threads to hardware resources.

See the API reference of the module for more details.

algorithms

The algorithms module exposes the full set of algorithms defined by the C++ standard. There is also partial support for C++ ranges.

See the *API reference* of the module for more details.

allocator_support

This module provides utilities for allocators. It contains `hpx::util::internal_allocator` which directly forwards allocation calls to `jemalloc`. This utility is is mainly useful on Windows.

See the API reference of the module for more details.

asio

The asio module is a thin wrapper around the Boost.Asio[254] library, providing a few additional helper functions.

See the *API reference* of the module for more details.

assertion

The assertion library implements the macros `HPX_ASSERT` and `HPX_ASSERT_MSG`. Those two macros can be used to implement assertions which are turned of during a release build.

By default, the location and function where the assert has been called from are displayed when the assertion fires. This behavior can be modified by using *`hpx::assertion::set_assertion_handler`*. When HPX initializes, it uses this function to specify a more elaborate assertion handler. If your application needs to customize this, it needs to do so before calling *hpx::init*, *hpx_main* or using the C-main wrappers.

See the *API reference* of the module for more details.

254 https://www.boost.org/doc/libs/release/doc/html/boost_asio.html

async_base

The async_base module defines the basic functionality for spawning tasks on thread pools. This module does not implement any functionality on its own, but is extended by *async_local* and *async_distributed* with implementations for the local and distributed cases.

See the *API reference* of this module for more details.

async_combinators

This module contains combinators for futures. The `when_*` functions allow you to turn multiple futures into a single future which is ready when all, any, some, or each of the given futures are ready. The `wait_*` combinators are equivalent to the `when_*` functions except that they do not return a future. Those wait for all futures to become ready before returning to the user. Note that the `wait_*` functions will rethrow one of the exceptions from exceptional futures. The `wait_*_nothrow` combinators are equivalent to the `wait_*` functions exception that they do not throw if one of the futures has become exceptional.

The `split_future` combinator takes a single future of a container (e.g. `tuple`) and turns it into a container of futures.

See *lcos_local*, *synchronization*, and *async_distributed* for other synchronization facilities.

See the *API reference* of this module for more details.

async_cuda

This library adds a simple API that enables the user to retrieve a future from a CUDA[255] stream. Typically, a user may launch one or more kernels and then get a future from the stream that will become ready when those kernels have completed. It is important to note that multiple kernels may be launched without fetching a future, and multiple futures may be obtained from the helper. Please refer to the unit tests and examples for further examples.

See the *API reference* of this module for more details.

async_local

This module extends *async_base* to provide local implementations of *hpx::async*, *hpx::post*, *hpx::sync*, and *hpx::dataflow*. The *async_distributed* module extends the functionality in this module to work with *action*s.

See the API reference of this module for more details.

[255] https://www.nvidia.com/object/cuda_home_new.html

async_mpi

The MPI library is intended to simplify the process of integrating MPI[256] based codes with the *HPX* runtime. Any MPI function that is asynchronous and uses an `MPI_Request` may be converted into an `hpx::future`. The syntax is designed to allow a simple replacement of the MPI call with a futurized async version that accepts an executor instead of a communicator, and returns a future instead of assigning a request. Typically, an MPI call of the form

```
int MPI_Isend(buf, count, datatype, rank, tag, comm, request);
```

becomes

```
hpx::future<int> f = hpx::async(executor,
↪ MPI_Isend, buf, count, datatype, rank, tag);
```

When the MPI operation is complete, the future will become ready. This allows communication to integrated cleanly with the rest of *HPX*, in particular the continuation style of programming may be used to build up more complex code. Consider the following example, that chains user processing, sends and receives using continuations…

```
// create an executor for MPI dispatch
hpx::mpi::experimental::executor exec(MPI_COMM_WORLD);

// post an asynchronous receive using MPI_Irecv
hpx::future<int> f_recv = hpx::async(
    exec, MPI_Irecv, &data, rank, MPI_INT, rank_from, i);

// attach a continuation to run when the recv completes,
f_recv.then([=, &tokens, &counter](auto&&)
{
    // call an application specific function
    msg_recv(rank, size, rank_to, rank_from, tokens[i], i);

    // send a new message
    hpx::future<int> f_send = hpx::async(
        exec, MPI_Isend, &tokens[i], 1, MPI_INT, rank_to, i);

    // when that send completes
    f_send.then([=, &tokens, &counter](auto&&)
    {
        // call an application specific function
        msg_send(rank, size, rank_to, rank_from, tokens[i], i);
    });
}
```

The example above makes use of `MPI_Isend` and `MPI_Irecv`, but *any* MPI function that uses requests may be futurized in this manner. The following is a (non exhaustive) list of MPI functions that *should* be supported, though not all have been tested at the time of writing (please report any problems to the issue tracker).

```
int MPI_Isend(...);
int MPI_Ibsend(...);
```

Note that the *HPX* mpi futurization wrapper should work with *any* asynchronous `MPI` call, as long as the function signature has the last two arguments `MPI_xxx(..., MPI_Comm comm, MPI_Request *request)` - internally these two parameters will be substituted by the executor and future data parameters that are supplied by template instantiations inside the `hpx::mpi` code.

See the API reference of this module for more details.

async_sycl

This module allows creating HPX futures using SYCL[257] events, effectively integrating asynchronous SYCL kernels and memory transfers with HPX. Building on this integration, this module also contains a SYCL executor. This executor encapsulates a SYCL queue. When SYCL queue member functions are launched with this executor, the user can automatically obtain the HPX futures associated with them.

The creation of the HPX futures using SYCL events is based on the same event polling mechanism that the CUDA HPX integration uses. Each registered event gets an associated callback and gets inserted into a callback vector to be polled by the scheduler in between tasks. Once the polling reveals the event is complete, the callback will be called, which in turn sets the future to ready (see sycl_event_callback.cpp). There are multiple adaptions for HipSYCL for this: To keep the runtime alive (avoiding the repeated on-the-fly creation of the runtime during the polling), we keep a default queue. Furthermore, we flush the internal SYCL DAG to ensure that the launched SYCL function is actually being executed.

[257] https://en.wikipedia.org/wiki/SYCL

The SYCL executor offers the usual post and async_execute functions. Additionally, it contains two get_future functions. One expects a pre-existing SYCL event to return a future, the other one does not but will launch an empty SYCL kernel instead, to obtain an event (causing higher overhead for the sake of being more convenient). The post and async_execute implementations here are actually different for HipSYCL and OneAPI, since the sycl::queue in OneAPI uses a different interface (using a code_location parameter) which requires some adaptations here.

To make this module compile, we use the -fno-sycl and -fsycl compiler parameters for the OneAPI use-case (requiring HPX to be compiled with dpcpp). For HipSYCL we use its cmake integration instead (requiring HPX to be compiled with clang++ and including HipSYCL as a library).

To build with OneAPI, use the CMake Variable HPX_WITH_SYCL=ON. To build with HipSYCL, use HPX_WITH_SYCL=ON and HPX_WITH_HIPSYCL=ON (and make sure find_package will find HipSYCL).

Lastly, the module contains three tests/examples. All three implement a simple vector add example. The first one obtains a future using the free method get_future, the second one uses a single SYCL executor and the last one is using multiple executors called from multiple host threads.

To build the tests, use " make tests.unit.modules.async_sycl " To run the tests, use "ctest -R sycl".

NOTE: Theoretically, this module could work with other SYCL implementations, but was only tested using OneAPI and HipSYCL so far.

See the *API reference* of this module for more details.

batch_environments

This module allows for the detection of execution as batch jobs, a series of programs executed without user intervention. All data is preselected and will be executed according to preset parameters, such as date or completion of another task. Batch environments are especially useful for executing repetitive tasks.

HPX supports the creation of batch jobs through the Portable Batch System (PBS) and SLURM.

For more information on batch environments, see *Running on batch systems* and the API reference for the module.

cache

This module provides two cache data structures:

- `hpx::util::cache::local_cache`
- `hpx::util::cache::lru_cache`

See the *API reference* of the module for more details.

checkpoint_base

The checkpoint_base module contains lower level facilities that wrap simple checkpointing capabilities. This module does not implement special handling for futures or components, but simply serializes all arguments to or from a given container.

This module exposes the `hpx::util::save_checkpoint_data`, `hpx::util::restore_checkpoint_data`, and `hpx::util::prepare_checkpoint_data` APIs. These functions encapsulate the basic serialization functionalities necessary to save/restore a variadic list of arguments to/from a given data container.

See the *API reference* of this module for more details.

command_line_handling_local

TODO: High-level description of the module.

See the API reference of this module for more details.

compute_local

TODO: High-level description of the module.

See the *API reference* of this module for more details.

concepts

This module provides helpers for emulating concepts. It provides the following macros:

- `HPX_CONCEPT_REQUIRES`
- `HPX_HAS_MEMBER_XXX_TRAIT_DEF`
- `HPX_HAS_XXX_TRAIT_DEF`

See the API reference of the module for more details.

concurrency

This module provides concurrency primitives useful for multi-threaded programming such as:

- *hpx::barrier*
- `hpx::util::cache_line_data` and `hpx::util::cache_aligned_data`: wrappers for aligning and padding data to cache lines.
- various lockfree queue data structures

See the API reference of the module for more details.

config

The config module contains various configuration options, typically hidden behind macros that choose the correct implementation based on the compiler and other available options. It also contains platform independent macros to control inlinining, export sets and more.

See the *API reference* of the module for more details.

config_registry

The config_registry module is a low level module providing helper functionality for registering configuration entries to a global registry from other modules. The `hpx::config_registry::add_module_config` function is used to add configuration options, and `hpx::config_registry::get_module_configs` can be used to retrieve configuration entries registered so far. `add_module_config_helper` can be used to register configuration entries through static global options.

See the API reference of this module for more details.

contracts

The contracts module provides C++ contracts support for HPX with intelligent fallback to assertions when native contracts are not available. This module implements a forward-compatible API that works across different C++ standards and compiler capabilities.

The module provides three primary macros: `HPX_PRE`, `HPX_POST`, and `HPX_CONTRACT_ASSERT`. These macros automatically adapt their behavior based on compiler capabilities:

- When C++26 native contracts are available (`__cpp_contracts` defined), they map to standard contract syntax
- When `HPX_WITH_CX26_CONTRACTS=OFF`, preconditions and postconditions become no-ops while contract assertions remain available as enhanced assertions

Configuration

Enable contracts in CMake:

```
cmake -DHPX_WITH_CXX26_CONTRACTS=ON -DCMAKE_CXX_STANDARD=26
```

Enable contract-enhanced assertions (optional):

```
cmake -DHPX_WITH_CXX26_
↪CONTRACTS=ON -DHPX_CONTRACTS_WITH_ASSERTS_AS_CONTRACT_ASSERTS=ON
```

Contract assertions work even when contracts are disabled:

```
cmake -DHPX_WITH_CXX26_
↪CONTRACTS=OFF  # HPX_CONTRACT_ASSERT still maps to HPX_ASSERT
```

Advanced Features

Contract-Enhanced Assertions

When HPX_CONTRACTS_WITH_ASSERTS_AS_CONTRACT_ASSERTS=ON is enabled, regular HPX_ASSERT calls are automatically upgraded to use contract assertions in C++26 mode:

```
void example_function(int value)
{
    HPX_ASSERT(value␣
↪> 0);  // Becomes contract_assert(value > 0) in C++26 mode
    // ... rest of function
}
```

Warning

Enhanced assertions only provide benefits when native C++26 contracts are supported by the compiler. Without native contract support, HPX_ASSERT -> HPX_CONTRACT_ASSERT -> HPX_ASSERT (no enhancement). CMake will issue a warning if you enable this option without native contract support.

This provides enhanced contract semantics throughout your existing codebase without requiring changes to assertion code. The transformation occurs in the contracts module (contracts.hpp) where the HPX_ASSERT macro is overridden to use HPX_CONTRACT_ASSERT when HPX_WITH_ASSERTS_AS_CONTRACT_ASSERTS=ON:

- HPX_WITH_CXX26_CONTRACTS=ON - Contracts module is enabled
- HPX_CONTRACTS_WITH_ASSERTS_AS_CONTRACT_ASSERTS=ON - Assertion enhancement is enabled

The implementation works by redefining HPX_ASSERT in contracts.hpp to use HPX_CONTRACT_ASSERT, which automatically adapts to the current contract mode (native C++26 contracts or assertion fallback). This ensures all existing HPX_ASSERT calls throughout the HPX codebase automatically gain contract semantics when available.

Usage Examples

Preconditions and postconditions using declaration syntax (C++26):

```
int divide(int a, int b) HPX_PRE(b != 0)
{
    return a / b;
}

int factorial(int n) HPX_PRE(n >= 0) HPX_POST(r; r > 0)
{
    return n <= 1 ? 1 : n * factorial(n - 1);
}
```

Contract assertions (available in all modes):

```
void process_array(std::vector<int>& arr, size_t index)
{
    HPX_CONTRACT_ASSERT(index < arr.size());
    arr[index] *= 2;
}
```

Design Philosophy

HPX_CONTRACT_ASSERT: Enhanced assertion mechanism
Available even when `HPX_WITH_CONTRACTS=OFF` because it provides value as an enhanced assertion. Maps to `HPX_ASSERT` in all configurations.

HPX_PRE/HPX_POST: True contract syntax
Represent language-level contract semantics. When contracts are enabled but native C++26 contracts are not available, these become no-ops to maintain forward compatibility. When `HPX_WITH_CONTRACTS=OFF`, they are also no-ops. This prepares for C++26 migration where they will be attached to function declarations rather than used in function bodies.

Migration Strategy

The module is designed for smooth migration to C++26 native contracts:

Current (transition mode):

```
int func(int x)
{
    HPX_
↪PRE(x > 0);     // No-op in fallback mode, active in native mode
    return x;
}
```

Target (C++26 native):

```
int func(int x) HPX_PRE(x > 0)
{
    return x;
}
```

Note: In fallback mode, `HPX_PRE` and `HPX_POST` become no-ops to maintain forward compatibility and avoid performance overhead. Use `HPX_CONTRACT_ASSERT` when you need runtime validation in all modes.

Testing

The module includes comprehensive testing with automatic compiler capability detection. Tests are organized into three categories:

- **Declaration tests**: Test C++26 native contract syntax when `__cpp_contracts` is available
- **Fallback tests**: Test assertion fallback behavior when contracts are not natively supported
- **Disabled tests**: Test no-op behavior when contracts are disabled

The test suite automatically detects compiler capabilities at configure time and builds only the appropriate tests for the current configuration.

See the *API reference* of the module for more details.

coroutines

The coroutines module provides coroutine (user-space thread) implementations for different platforms.

See the *API reference* of the module for more details.

datastructures

The datastructures module provides basic data structures (typically provided for compatibility with older C++ standards):

- `hpx::detail::small_vector`
- `hpx::util::basic_any`
- `hpx::util::member_pack`
- `hpx::optional`
- *hpx::tuple*
- `hpx::variant`

See the *API reference* of the module for more details.

debugging

This module provides helpers for demangling symbol names.

See the *API reference* of the module for more details.

errors

This module provides support for exceptions and error codes:

- *hpx::exception*
- *hpx::error_code*
- `hpx::error`

See the *API reference* of the module for more details.

execution

This library implements executors and execution policies for use with parallel algorithms and other facilities related to managing the execution of tasks.

See the *API reference* of the module for more details.

execution_base

The basic execution module is the main entry point to implement parallel and concurrent operations. It is modeled after P0443[258] with some additions and implementations for the described concepts. Most notably, it provides an abstraction for execution resources, execution contexts and execution agents in such a way, that it provides customization points that those aforementioned concepts can be replaced and combined with ease.

For that purpose, three virtual base classes are provided to be able to provide implementations with different properties:

- **`resource_base`: This is the abstraction for execution resources, that is** for example CPU cores or an accelerator.
- **`context_base`: An execution context uses execution resources and is able** to spawn new execution agents, as new threads of executions on the available resources.
- **`agent_base`: The execution agent represents the thread of execution, and** can be used to yield, suspend, resume or abort a thread of execution.

executors

The executors module exposes executors and execution policies. Most importantly, it exposes the following classes and constants:

- `hpx::execution::sequenced_executor`
- `hpx::execution::parallel_executor`
- *hpx::execution::sequenced_policy*
- *hpx::execution::parallel_policy*
- *hpx::execution::parallel_unsequenced_policy*
- *hpx::execution::sequenced_task_policy*
- *hpx::execution::parallel_task_policy*
- *hpx::execution::seq*

[258] http://wg21.link/p0443

- *hpx::execution::par*
- *hpx::execution::par_unseq*
- *hpx::execution::task*

See the *API reference* of this module for more details.

filesystem

This module provides a compatibility layer for the C++17 filesystem library. If the filesystem library is available this module will simply forward its contents into the `hpx::filesystem` namespace. If the library is not available it will fall back to Boost.Filesystem instead.

See the *API reference* of the module for more details.

format

The format module exposes the `format` and `format_to` functions for formatting strings.

See the API reference of the module for more details.

functional

This module provides function wrappers and helpers for managing functions and their arguments.

- *hpx::function*
- *hpx::function_ref*
- *hpx::move_only_function*
- *hpx::bind*
- *hpx::bind_back*
- *hpx::bind_front*
- `hpx::util::deferred_call`
- *hpx::invoke*
- `hpx::invoke_r`
- *hpx::invoke_fused*
- *hpx::invoke_fused_r*
- *hpx::mem_fn*
- `hpx::util::one_shot`
- `hpx::util::protect`
- `hpx::util::result_of`
- *hpx::placeholders::_1*
- *hpx::placeholders::_2*
- …

- *hpx::placeholders::_9*

See the *API reference* of the module for more details.

futures

This module defines the *hpx::future* and *hpx::shared_future* classes corresponding to the C++ standard library classes std::future[259] and std::shared_future[260]. Note that the specializations of `hpx::future::then` for executors and execution policies are defined in the *execution* module.

See the *API reference* of this module for more details.

hardware

The hardware module abstracts away hardware specific details of timestamps and CPU features.

See the API reference of the module for more details.

hashing

The hashing module provides two hashing implementations:

- `hpx::util::fibhash`
- `hpx::util::jenkins_hash`

See the API reference of the module for more details.

include_local

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together. This module provides local-only headers.

See the API reference of this module for more details.

ini

TODO: High-level description of the module.

See the API reference of this module for more details.

[259] http://en.cppreference.com/w/cpp/thread/future
[260] http://en.cppreference.com/w/cpp/thread/shared_future

init_runtime_local

TODO: High-level description of the module.

See the API reference of this module for more details.

io_service

This module provides an abstraction over Boost.ASIO, combining multiple `asio::io_contexts` into a single pool. *`hpx::util::io_service_pool`* provides a simple pool of `asio::io_contexts` with an API similar to `asio::io_context`. `hpx::threads::detail::io_service_thread_pool` wraps *`hpx::util::io_service_pool`* into an interface derived from `hpx::threads::detail::thread_pool_base`.

See the *API reference* of this module for more details.

iterator_support

This module provides helpers for iterators. It provides `hpx::util::iterator_facade` and `hpx::util::iterator_adaptor` for creating new iterators, and the trait `hpx::util::is_iterator` along with more specific iterator traits.

See the API reference of the module for more details.

itt_notify

This module provides support for profiling with Intel VTune[261].

See the API reference of this module for more details.

lci_base

This module provides helper functionality for detecting LCI environments.

See the API reference of this module for more details.

lcos_local

This module provides the following local *LCO*s:

- *hpx::lcos::local::and_gate*
- `hpx::lcos::local::channel`
- `hpx::lcos::local::one_element_channel`
- `hpx::lcos::local::receive_channel`
- `hpx::lcos::local::send_channel`
- `hpx::lcos::local::guard`
- `hpx::lcos::local::guard_set`

[261] https://software.intel.com/content/www/us/en/develop/tools/vtune-profiler.html

- `hpx::lcos::local::run_guarded`
- `hpx::lcos::local::conditional_trigger`
- *hpx::packaged_task*
- *hpx::promise*
- `hpx::lcos::local::receive_buffer`
- *`hpx::lcos::local::trigger`*

See *lcos_distributed* for distributed LCOs. Basic synchronization primitives for use in *HPX* threads can be found in *synchronization*. *async_combinators* contains useful utility functions for combining futures.

See the *API reference* of this module for more details.

likwid

TODO: High-level description of the module.

See the API reference of this module for more details.

lock_registration

This module contains fucntionality for registering locks to detect when they are locked and unlocked on different threads.

See the API reference of this module for more details.

logging

This module provides useful macros for logging information.

See the API reference of the module for more details.

memory

Part of this module is a forked version of `boost::intrusive_ptr` from Boost.SmartPtr[262].

See the API reference of the module for more details.

mpi_base

This module provides helper functionality for detecting MPI[263] environments.

See the API reference of this module for more details.

[262] https://www.boost.org/doc/libs/release/libs/smart_ptr/doc/html/smart_ptr.html
[263] https://en.wikipedia.org/wiki/Message_Passing_Interface

pack_traversal

This module exposes the basic functionality for traversing various packs, both synchronously and asynchronously: `hpx::util::traverse_pack` and *hpx::util::traverse_pack_async*. It also exposes the higher level functionality of unwrapping nested futures: `hpx::util::unwrap` and its function object form `hpx::util::functional::unwrap`.

See the *API reference* of this module for more details.

plugin

This module provides base utilities for creating plugins.

See the API reference of the module for more details.

prefix

This module provides utilities for handling the prefix of an *HPX* application, i.e. the paths used for searching components and plugins.

See the API reference of this module for more details.

preprocessor

This library contains useful preprocessor macros:

- *HPX_PP_CAT*: Concatenate two tokens
- *HPX_PP_EXPAND*: Expands a preprocessor token
- *HPX_PP_NARGS*: Determines the number of arguments passed to a variadic macro
- *HPX_PP_STRINGIZE*: Turns a token into a string
- *HPX_PP_STRIP_PARENS*: Strips parenthesis from a token

See the *API reference* of the module for more details.

program_options

The module program_options is a direct fork of the Boost.Program_options[264] library (Boost V1.70.0[265]). In order to be included as an *HPX* module, the Boost.Program_options library has been moved to the `namespace hpx::program_options`. We have also replaced all Boost facilities the library depends on with either the equivalent facilities from the standard library or from *HPX*. As a result, the *HPX* program_options module is fully interface compatible with Boost.Program_options (sans the `hpx` namespace and the `#include <hpx/modules/program_options.hpp>` changes that need to be applied to all code relying on this library).

All credit goes to Vladimir Prus, the author of the excellent Boost.Program_options library. All bugs have been introduced by us.

See the API reference of the module for more details.

[264] https://www.boost.org/doc/html/program_options.html
[265] https://www.boost.org/doc/libs/1_70_0/doc/html/program_options.html

properties

This module implements the `prefer` customization point for properties in terms of P2220[266]. This differs from P1393[267] in that it relies fully on `tag_invoke` overloads and fewer base customization points. Actual properties are defined in modules. All functionality is experimental and can be accessed through the `hpx::experimental` namespace.

See the API reference of this module for more details.

resiliency

In *HPX*, a program failure is a manifestation of a failing task. This module exposes several APIs that allow users to manage failing tasks in a convenient way by either replaying a failed task or by replicating a specific task.

Task replay is analogous to the Checkpoint/Restart mechanism found in conventional execution models. The key difference being localized fault detection. When the runtime detects an error, it replays the failing task as opposed to completely rolling back the entire program to the previous checkpoint.

Task replication is designed to provide reliability enhancements by replicating a set of tasks and evaluating their results to determine a consensus among them. This technique is most effective in situations where there are few tasks in the critical path of the DAG which leaves the system underutilized or where hardware or software failures may result in an incorrect result instead of an error. However, the drawback of this method is the additional computational cost incurred by repeating a task multiple times.

The following API functions are exposed:

- *`hpx::resiliency::experimental::async_replay`*: This version of task replay will catch user-defined exceptions and automatically reschedule the task N times before throwing an `hpx::resiliency::experimental::abort_replay_exception` if no task is able to complete execution without an exception.
- *`hpx::resiliency::experimental::async_replay_validate`*: This version of replay adds an argument to async replay which receives a user-provided validation function to test the result of the task against. If the task's output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries has been exceeded.
- *`hpx::resiliency::experimental::async_replicate`*: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors.
- *`hpx::resiliency::experimental::async_replicate_validate`*: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned.
- *`hpx::resiliency::experimental::async_replicate_vote`*: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every

[266] https://wg21.link/p2220
[267] http://wg21.link/p1393

version of the task. In order to determine which return value is "correct", the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the "correct"" answer.

- *hpx::resiliency::experimental::async_replicate_vote_validate*: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a "voting function" which returns the consensus formed by the voting logic.
- *hpx::resiliency::experimental::dataflow_replay*: This version of dataflow replay will catch user-defined exceptions and automatically reschedules the task N times before throwing an `hpx::resiliency::experimental::abort_replay_exception` if no task is able to complete execution without an exception. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- *hpx::resiliency::experimental::dataflow_replay_validate* : This version of replay adds an argument to dataflow replay which receives a user-provided validation function to test the result of the task against. If the task's output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries have been exceeded. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- *hpx::resiliency::experimental::dataflow_replicate*: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- *hpx::resiliency::experimental::dataflow_replicate_validate*: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- *hpx::resiliency::experimental::dataflow_replicate_vote*: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is "correct", the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the "correct" answer. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- *hpx::resiliency::experimental::dataflow_replicate_vote_validate*: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a "voting function" which returns the consensus formed by the voting logic. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

See the *API reference* of the module for more details.

resource_partitioner

The resource_partitioner module defines `hpx::resource::partitioner`, the class used by the runtime and users to partition available hardware resources into thread pools. See *Using the resource partitioner* for more details on using the resource partitioner in applications.

See the API reference of this module for more details.

runtime_configuration

This module handles the configuration options required by the runtime.

See the *API reference* of this module for more details.

runtime_local

TODO: High-level description of the library.

See the *API reference* of this module for more details.

schedulers

This module provides schedulers used by thread pools in the *thread_pools* module. There are currently three main schedulers:

- `hpx::threads::policies::local_priority_queue_scheduler`
- `hpx::threads::policies::static_priority_queue_scheduler`
- `hpx::threads::policies::shared_priority_queue_scheduler`

Other schedulers are specializations or variations of the above schedulers. See the examples of the *resource_partitioner* module for examples of specifying a custom scheduler for a thread pool.

See the API reference of this module for more details.

serialization

This module provides serialization primitives and support for all built-in types as well as all C++ Standard Library collection and utility types. This list is extended by *HPX* vocabulary types with proper support for global reference counting. *HPX*'s mode of serialization is derived from Boost's serialization model[268] and, as such, is mostly interface compatible with its Boost counterpart.

The purest form of serializing data is to copy the content of the payload bit by bit; however, this method is impractical for generic C++ types, which might be composed of more than just regular built-in types. Instead, *HPX*'s approach to serialization is derived from the Boost Serialization library, and is geared towards allowing the programmer of a given class explicit control and syntax of what to serialize. It is based on operator overloading of two special archive types that hold a buffer or stream to store the serialized data and is responsible for dispatching the serialization mechanism to the intrusive or non-intrusive version. The serialization process is recursive. Each member

[268] https://www.boost.org/doc/libs/1_72_0/libs/serialization/doc/index.html

that needs to be serialized must be specified explicitly. The advantage of this approach is that the serialization code is written in C++ and leverages all necessary programming techniques. The generic, user-facing interface allows for effective application of the serialization process without obstructing the algorithms that need special code for packing and unpacking. It also allows for optimizations in the implementation of the archives.

See the *API reference* of the module for more details.

static_reinit

This module provides a simple wrapper around static variables that can be reinitialized.

See the *API reference* of this module for more details.

string_util

This module contains string utilities inspired by the Boost String Algorithms Library.

See the API reference of this module for more details.

synchronization

This module provides synchronization primitives that should be used rather than the C++ standard ones in *HPX* threads:

- *hpx::barrier*
- *hpx::binary_semaphore*
- *hpx::call_once*
- *hpx::condition_variable*
- *hpx::condition_variable_any*
- *hpx::counting_semaphore*

See *lcos_local*, *async_combinators*, and *async_distributed* for higher level synchronization facilities.

See the *API reference* of this module for more details.

tag_invoke

TODO: High-level description of the module.

See the *API reference* of this module for more details.

testing

The testing module contains useful macros for testing. The results of tests can be printed with `hpx::util::report_errors`. The following macros are provided:

- `HPX_TEST`
- `HPX_TEST_MSG`
- `HPX_TEST_EQ`
- `HPX_TEST_NEQ`
- `HPX_TEST_LT`
- `HPX_TEST_LTE`
- `HPX_TEST_RANGE`
- `HPX_TEST_EQ_MSG`
- `HPX_TEST_NEQ_MSG`
- `HPX_SANITY`
- `HPX_SANITY_MSG`
- `HPX_SANITY_EQ`
- `HPX_SANITY_NEQ`
- `HPX_SANITY_LT`
- `HPX_SANITY_LTE`
- `HPX_SANITY_RANGE`
- `HPX_SANITY_EQ_MSG`

See the API reference of the module for more details.

thread_pool_util

This module contains helper functions for asynchronously suspending and resuming thread pools and their worker threads.

See the *API reference* of this module for more details.

thread_pools

This module defines the thread pools and utilities used by the *HPX* runtime. The only thread pool implementation provided by this module is `hpx::threads::detail::scheduled_thread_pool`, which is derived from `hpx::threads::detail::thread_pool_base` defined in the *threading_base* module.

See the API reference of this module for more details.

thread_support

This module provides miscellaneous utilities for threading and concurrency.

See the *API reference* of the module for more details.

threading

This module provides the equivalents of `std::thread` and `std::jthread` for lightweight *HPX* threads:

- *hpx::thread*
- *hpx::jthread*

See the *API reference* of this module for more details.

threading_base

This module contains the base class definition required for threads. The base class *`hpx::threads::thread_data`* is inherited by two specializations for stackful and stackless threads: `hpx::threads::thread_data_stackful` and `hpx::threads::thread_data_stackless`. In addition, the module defines the base classes for schedulers and thread pools: `hpx::threads::policies::scheduler_base` and *`hpx::threads::thread_pool_base`*.

See the API reference of this module for more details.

thread_manager

This module defines the *hpx::threads::threadmanager* class. This is used by the runtime to manage the creation and destruction of thread pools. The *resource_partitioner* module handles the partitioning of resources into thread pools, but not the creation of thread pools.

See the API reference of this module for more details.

thrust

The thrust module integrates *HPX* parallel algorithms with NVIDIA Thrust, enabling GPU acceleration using familiar *HPX* algorithm syntax.

Execution Policies

hpx::thrust::thrust_host_policy
CPU execution using optimized parallel implementations

hpx::thrust::thrust_device_policy
Synchronous GPU execution

hpx::thrust::thrust_task_policy
Asynchronous GPU execution returning *HPX* futures

Policy Mappings

The *HPX* thrust policies map directly to Thrust execution policies:

```
// Policy mappings
hpx::thrust::thrust_host_policy    -> thrust::host
hpx::thrust::thrust_device_policy  -> thrust::device
hpx::thrust::thrust_task_policy    -> thrust::par_nosync
```

Usage

Synchronous Device Execution

```
#include <hpx/modules/thrust.hpp>
#include <thrust/device_vector.h>

hpx::thrust::thrust_device_policy device{};
thrust::device_vector<int> d_vec(1000, 0);

hpx::fill(device, d_vec.begin(), d_vec.end(), 42);
int sum = hpx::reduce(device, d_vec.begin(), d_vec.end(), 0);
```

Asynchronous Execution with Futures

```
#include <hpx/modules/async_cuda.hpp>
#include <hpx/modules/thrust.hpp>

int hpx_main() {
    // Required for async operations
    hpx::cuda::experimental::enable_
↪user_polling polling_guard("default");

    hpx::thrust::thrust_task_policy task{};
    thrust::device_vector<int> d_vec(1000, 1);

    auto␣
↪fill_future = hpx::fill(task, d_vec.begin(), d_vec.end(), 42);
    fill_future.get();  // Standard HPX future operations

}
```

Build Requirements

- CUDA Toolkit 12.4.0+
- *HPX* with `HPX_WITH_CUDA=ON`
- Enable with: `cmake -DHPX_WITH_CUDA=ON ...`

See Also

- *async_cuda* - CUDA integration
- *execution* - *HPX* execution policies

timed_execution

This module provides extensions to the executor interfaces defined in the *execution* module that allow timed submission of tasks on thread pools (at or after a specified time).

See the *API reference* of this module for more details.

timing

This module provides the timing utilities (clocks and timers).

See the *API reference* of the module for more details.

topology

This module provides the class `hpx::threads::topology` which represents the hardware resources available on a node. The class is a light wrapper around the Portable Hardware Locality (HWLOC)[269] library. The `hpx::threads::cpu_mask` is a small companion class that represents a set of resources on a node.

See the *API reference* of the module for more details.

tracing

This module provides the *HPX* tracing abstraction: a compile-time-dispatched API that annotates *HPX* runtime events (task lifecycle, futures, parcels, work stealing, worker sleep, and more) and routes those annotations to a single profiler backend selected at build time.

Three profiler backends are supported, with a no-op fallback when none is enabled. `HPX_SetupTracing.cmake` errors out at configure time if more than one of *`HPX_WITH_APEX`*, *`HPX_WITH_ITTNOTIFY`* or *`HPX_WITH_TRACY`* is enabled.

- *tracy* — the Tracy[270] profiler, enabled with *`HPX_WITH_TRACY`*.
- Intel ITT API[271], enabled with *`HPX_WITH_ITTNOTIFY`*.
- APEX[272], enabled with *`HPX_WITH_APEX`*.
- an empty backend when none of the above is enabled — the C++ hooks are `constexpr` no-ops and the tracing macros expand to nothing, so the hooks compile away when tracing is disabled.

Include `hpx/modules/tracing.hpp` to get the public API; it dispatches at compile time to one of the per-backend headers under `hpx/tracing/backends/` . Entries are declared in the `hpx::tracing` namespace and the dispatch macros (`HPX_TRACING_MARK_EVENT`, `HPX_TRACING_ZONE`, `HPX_TRACING_PAUSE`, `HPX_TRACING_RESUME`) live in `hpx/tracing/macros.hpp`.

See *Tracy integration* for how to build *HPX* against Tracy and attach the profiler.

tracy

This module enables the integration of *HPX* applications with the Tracy[273] profiler. See *tracing* for the backend abstraction that dispatches to Tracy at compile time, and *Tracy integration* for how to build *HPX* against Tracy and attach the profiler.

type_support

This module provides helper facilities related to types.

See the API reference of the module for more details.

util

The util module provides miscellaneous standalone utilities.

See the *API reference* of the module for more details.

version

This module macros and functions for accessing version information about *HPX* and its dependencies.

See the *API reference* of this module for more details.

2.8.2 Main *HPX* modules

actions

TODO: High-level description of the library.

See the *API reference* of this module for more details.

actions_base

TODO: High-level description of the library.

See the *API reference* of this module for more details.

agas

TODO: High-level description of the module.

See the *API reference* of this module for more details.

agas_base

This module holds the implementation of the four AGAS services: primary namespace, locality namespace, component namespace, and symbol namespace.

See the *API reference* of this module for more details.

async_colocated

TODO: High-level description of the module.

See the *API reference* of this module for more details.

async_distributed

This module contains functionality for asynchronously launching work on remote localities: *hpx::async*, *hpx::post*. This module extends the local-only functions in libs_async_local.

See the API reference of this module for more details.

checkpoint

A common need of users is to periodically backup an application. This practice provides resiliency and potential restart points in code. *HPX* utilizes the concept of a `checkpoint` to support this use case.

Found in `hpx/util/checkpoint.hpp`, `checkpoint`s are defined as objects that hold a serialized version of an object or set of objects at a particular moment in time. This representation can be stored in memory for later use or it can be written to disk for storage and/or recovery at a later point. In order to create and fill this object with data, users must use a function called `save_checkpoint`. In code the function looks like this:

```
hpx::future<hpx::util::checkpoint>
↪ hpx::util::save_checkpoint(a, b, c, ...);
```

`save_checkpoint` takes arbitrary data containers, such as `int`, `double`, `float`, `vector`, and `future`, and serializes them into a newly created `checkpoint` object. This function returns a `future` to a `checkpoint` containing the data. Here's an example of a simple use case:

```
using hpx::util::checkpoint;
using hpx::util::save_checkpoint;

std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> save_checkpoint(vec);
```

Once the future is ready, the checkpoint object will contain the `vector` `vec` and its five elements.

`prepare_checkpoint` takes arbitrary data containers (same as for `save_checkpoint`), , such as `int`, `double`, `float`, `vector`, and `future`, and calculates the necessary buffer space for the checkpoint that would be created if `save_checkpoint` was called with the same arguments. This function returns a `future` to a `checkpoint` that is appropriately initialized. Here's an example of a simple use case:

```
using hpx::util::checkpoint;
using hpx::util::prepare_checkpoint;

std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> prepare_checkpoint(vec);
```

Once the future is ready, the checkpoint object will be initialized with an appropriately sized internal buffer.

It is also possible to modify the launch policy used by `save_checkpoint`. This is accomplished by passing a launch policy as the first argument. It is important to note that passing `hpx::launch::sync` will cause `save_checkpoint` to return a `checkpoint` instead of a `future` to a `checkpoint`. All other policies passed to `save_checkpoint` will return a `future` to a `checkpoint`.

Sometimes `checkpoint` s must be declared before they are used. `save_checkpoint` allows users to move pre-created `checkpoint` s into the function as long as they are the first container passing into the function (In the case where a launch policy is used, the `checkpoint` will immediately follow the launch policy). An example of these features can be found below:

```
    char character = 'd';
    int integer = 10;
    float flt = 10.01f;
    bool boolean = true;
    std::string str = "I am a string of characters";
    std::vector<char> vec(str.begin(), str.end());
    checkpoint archive;

    // Test 1
    //  test basic functionality
    hpx::shared_future<checkpoint> f_archive = save_checkpoint(
        std::move(archive), character, integer, flt, boolean, str, vec);
```

Once users can create `checkpoints` they must now be able to restore the objects they contain into memory. This is accomplished by the function `restore_checkpoint`. This function takes a `checkpoint` and fills its data into the containers it is provided. It is important to remember that the containers must be ordered in the same way they were placed into the `checkpoint`. For clarity see the example below:

```
    char character2;
    int integer2;
    float flt2;
    bool boolean2;
    std::string str2;
    std::vector<char> vec2;

    restore_checkpoint(data,
 character2, integer2, flt2, boolean2, str2, vec2);
```

The core utility of `checkpoint` is in its ability to make certain data persistent. Often, this means that the data needs to be stored in an object, such as a file, for later use. *HPX* has two solutions for these issues: stream operator overloads and access iterators.

HPX contains two stream overloads, `operator<<` and `operator>>`, to stream data out of and into `checkpoint`. Here is an example of the overloads in use below:

```
    double a9 = 1.0, b9 = 1.1, c9 = 1.2;
    std::ofstream test_file_9("test_file_9.txt");
    hpx::future<checkpoint> f_9 = save_checkpoint(a9, b9, c9);
```

(continues on next page)

(continued from previous page)

```
    test_file_9 << f_9.get();
    test_file_9.close();

    double a9_1, b9_1, c9_1;
    std::ifstream test_file_9_1("test_file_9.txt");
    checkpoint archive9;
    test_file_9_1 >> archive9;
    restore_checkpoint(archive9, a9_1, b9_1, c9_1);
```

This is the primary way to move data into and out of a `checkpoint`. It is important to note, however, that users should be cautious when using a stream operator to load data and another function to remove it (or vice versa). Both `operator<<` and `operator>>` rely on a `.write()` and a `.read()` function respectively. In order to know how much data to read from the `std::istream`, the `operator<<` will write the size of the `checkpoint` before writing the `checkpoint` data. Correspondingly, the `operator>>` will read the size of the stored data before reading the data into a new instance of `checkpoint`. As long as the user employs the `operator<<` and `operator>>` to stream the data, this detail can be ignored.

Important

Be careful when mixing `operator<<` and `operator>>` with other facilities to read and write to a `checkpoint`. `operator<<` writes an extra variable, and `operator>>` reads this variable back separately. Used together the user will not encounter any issues and can safely ignore this detail.

Users may also move the data into and out of a `checkpoint` using the exposed `.begin()` and `.end()` iterators. An example of this use case is illustrated below.

```
    std::ofstream test_file_7("checkpoint_test_file.txt");
    std::vector<float> vec7{1.02f, 1.03f, 1.04f, 1.05f};
    hpx::future<checkpoint> fut_7 = save_checkpoint(vec7);
    checkpoint archive7 = fut_7.get();
    std::copy(archive7.begin(),    // Write data to ofstream
        archive7.end(),            // ie. the file
        std::ostream_iterator<char>(test_file_7));
    test_file_7.close();

    std::vector<float> vec7_1;
    std::vector<char> char_vec;
    std::ifstream test_file_7_1("checkpoint_test_file.txt");
    if (test_file_7_1)
    {
        test_file_7_1.seekg(0, test_file_7_1.end);
        auto length = test_file_7_1.tellg();
        test_file_7_1.seekg(0, test_file_7_1.beg);
        char_vec.resize(length);
        test_file_7_1.read(char_vec.data(), length);
    }
    checkpoint␣
↪archive7_1(std::move(char_vec));    // Write data to checkpoint
```

(continues on next page)

(continued from previous page)

```
restore_checkpoint(archive7_1, vec7_1);
```

Checkpointing components

save_checkpoint and restore_checkpoint are also able to store components inside checkpoints. This can be done in one of two ways. First a client of the component can be passed to save_checkpoint. When the user wishes to resurrect the component she can pass a client instance to restore_checkpoint.

This technique is demonstrated below:

```
// Try to checkpoint and restore a component with a client
std::vector<int> vec3{10, 10, 10, 10, 10};

// Create a component instance through client constructor
data_client D(hpx::find_here(), std::move(vec3));
hpx::future<checkpoint> f3 = save_checkpoint(D);

// Create a new client
data_client E;

// Restore server inside client instance
restore_checkpoint(f3.get(), E);
```

The second way a user can save a component is by passing a shared_ptr to the component to save_checkpoint. This component can be resurrected by creating a new instance of the component type and passing a shared_ptr to the new instance to restore_checkpoint.

This technique is demonstrated below:

```
// test checkpoint a component using a shared_ptr
std::vector<int> vec{1, 2, 3, 4, 5};
data_client A(hpx::find_here(), std::move(vec));

// Checkpoint Server
hpx::id_type old_id = A.get_id();

hpx::future<std::shared_ptr<data_server>> f_a_ptr =
    hpx::get_ptr<data_server>(A.get_id());
std::shared_ptr<data_server> a_ptr = f_a_ptr.get();
hpx::future<checkpoint> f = save_checkpoint(a_ptr);
auto&& data = f.get();

// test prepare_checkpoint API
checkpoint c = prepare_checkpoint(hpx::launch::sync, a_ptr);
HPX_TEST(c.size() == data.size());

// Restore Server
// Create a new server instance
std::shared_ptr<data_server> b_server;
restore_checkpoint(data, b_server);
```

collectives

The collectives module exposes a set of distributed collective operations. Those can be used to exchange data between participating sites in a coordinated way. At this point the module exposes the following collective primitives:

- *hpx::collectives::all_gather*: receives a set of values from all participating sites.
- *hpx::collectives::all_reduce*: performs a reduction on data from each participating site to each participating site.
- *hpx::collectives::all_to_all*: each participating site provides its element of the data to collect while all participating sites receive the data from every other site.
- *hpx::collectives::broadcast_to* and *hpx::collectives::broadcast_from*: performs a broadcast operation from a root site to all participating sites.
- *hpx::collectives::exclusive_scan*: performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.
- *hpx::collectives::gather_here* and *hpx::collectives::gather_there*: gathers values from all participating sites.
- *hpx::collectives::inclusive_scan*: performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.
- *hpx::collectives::reduce_here* and *hpx::collectives::reduce_there*: performs a reduction on data from each participating site to a root site.
- *hpx::collectives::scatter_to* and *hpx::collectives::scatter_from*: receives an element of a set of values operating on the given base name.
- *hpx::lcos::broadcast*: performs a given action on all given global identifiers.
- *hpx::distributed::barrier*: distributed barrier.
- *hpx::lcos::fold*: performs a fold with a given action on all given global identifiers.
- *hpx::distributed::latch*: distributed latch.
- *hpx::lcos::reduce*: performs a reduction on data from each given global identifiers.
- *hpx::lcos::spmd_block*: performs the same operation on a local image while providing handles to the other images.

See the *API reference* of the module for more details.

Hierarchical collectives

Hierarchical communicators split a collective into sub-communicators arranged as a tree. This reduces the number of participants in each individual operation, but it also means that one user-visible hierarchical call can touch several internal communicators.

Generation model

Hierarchical collectives use two internal generations for each user generation. For a user generation `k`, the first internal phase uses `2k - 1` and the second uses `2k`. Single-pass hierarchical operations and the inter-group exchange of *hpx::collectives::all_to_all* advance the communicator by two generations in one step so that shared hierarchical communicators stay aligned with two-phase collectives.

When a hierarchical communicator instance is shared between collective operations, callers must pass explicit, strictly consecutive positive generation numbers. Two-phase hierarchical collectives, including *hpx::collectives::all_gather*, *hpx::collectives::all_reduce*, *hpx::collectives::all_to_all*, *hpx::collectives::inclusive_scan*, *hpx::collectives::exclusive_scan*, and *hpx::distributed::barrier*, reject the default generation because their phase generations are derived from the explicit user generation.

command_line_handling

The command_line_handling module defines and handles the command-line options required by the *HPX* runtime, combining them with configuration options defined by the *runtime_configuration* module. The actual parsing of command line options is handled by the *program_options* module.

See the API reference of the module for more details.

components

TODO: High-level description of the module.

See the *API reference* of this module for more details.

components_base

TODO: High-level description of the library.

See the *API reference* of this module for more details.

compute

The compute module provides utilities for handling task and memory affinity on host systems.

See the *API reference* of the module for more details.

distribution_policies

TODO: High-level description of the module.

See the *API reference* of this module for more details.

execution_distributed

Provides distributed sender and receiver facilities for HPX execution.

See the *API reference* of this module for more details.

executors_distributed

This module provides the executor `hpx::execution::experimental::distribution_policy_executor`. It allows one to create work that is implicitly distributed over multiple localities.

See the *API reference* of this module for more details.

include

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together.

See the *API reference* of this module for more details.

init_runtime

TODO: High-level description of the library.

See the *API reference* of this module for more details.

lcos_distributed

This module contains distributed *LCO*s. Currently the only LCO provided is `hpx::lcos::channel`, a construct for sending values from one *locality* to another. See libs_lcos_local for local LCOs.

See the API reference of this module for more details.

naming

TODO: High-level description of the module.

See the API reference of this module for more details.

naming_base

This module provides a forward declaration of *address_type*, *component_type* and *invalid_locality_id*.

See the *API reference* of this module for more details.

parcelport_lci

TODO: High-level description of the module.

See the API reference of this module for more details.

parcelport_mpi

TODO: High-level description of the module.

See the API reference of this module for more details.

parcelport_tcp

TODO: High-level description of the module.

See the API reference of this module for more details.

parcelset

TODO: High-level description of the module.

See the *API reference* of this module for more details.

parcelset_base

TODO: High-level description of the module.

See the *API reference* of this module for more details.

performance_counters

This module provides the basic functionality required for defining performance counters. See *Performance counters* for more information about performance counters.

See the API reference of this module for more details.

plugin_factories

TODO: High-level description of the module.

See the *API reference* of this module for more details.

resiliency_distributed

Software resiliency features of *HPX* were introduced in the *resiliency module*. This module extends the APIs to run on distributed-memory systems allowing the user to invoke the failing task on other localities at runtime. This is useful in cases where a node is identified to fail more often (e.g., for certain ALU computes) as the task can now be replayed or replicated among different localities. The API exposed allows for an easy integration with the local only resiliency APIs as well.

Distributed software resilience APIs have a similar function signature and lives under the same namespace of `hpx::resiliency::experimental`. The difference arises in the formal parameters where distributed APIs takes the localities as the first argument, and an action as opposed to a function or a function object. The localities signify the order in which the API will either schedule (in case of Task Replay) tasks in a round robin fashion or replicate the tasks onto the list of localities.

The list of APIs exposed by distributed resiliency modules is the same as those defined in *local resiliency module*.

See the *API reference* of this module for more details.

runtime_components

TODO: High-level description of the module.

See the *API reference* of this module for more details.

runtime_distributed

TODO: High-level description of the module.

See the *API reference* of this module for more details.

segmented_algorithms

Segmented algorithms extend the usual parallel *algorithms* by providing overloads that work with distributed containers, such as partitioned vectors.

See the *API reference* of the module for more details.

statistics

This module provide some statistics utilities like rolling min/max and histogram.

See the API reference of the module for more details.

Supervision module

The supervision module provides lifecycle event publication, state querying, and observer registration for actors/components running on local or remote localities.

Overview

Several core operations are exposed, each with a local (synchronous) call and a remote (locality-qualified, future-returning or `launch::sync_policy`) call:

Functions

Table 2.125: *hpx::supervision* functions

Function	Description
hpx::supervision::publish_event	*Publish a lifecycle event for a target.*
hpx::supervision::query_state	*Query the most recently observed lifecycle state.*
hpx::supervision::register_observer	*Register an observer for a target's lifecycle events.*
hpx::supervision::unregister_observer	*Unregister a previously registered lifecycle observer.*
hpx::supervision::remove_target	*Clear all locally tracked state for a target.*
hpx::supervision::await_terminal	*Wait for a target to reach a terminal lifecycle event.*
hpx::supervision::check_admission	*Check whether a target currently admits new dispatch.*
hpx::supervision::register_activity_observer	*Register an observer for activity-state transitions of all targets.*
hpx::supervision::unregister_activity_observer	*Unregister a previously registered activity observer.*

Publishing events

hpx::*future*<*hpx*::*supervision*::publish_result> `hpx::supervision::publish_event`(*hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0)

hpx::*supervision*::publish_result `hpx::supervision::publish_event`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *hpx*::*throws*) *hpx*::*supervision*::publish_result `hpx::supervision::publish_event`(*hpx*::id_type const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *hpx*::*throws*)

Publish a lifecycle event for `target`. Events are visible immediately to local observers; remote observers are notified within roughly one to two parcel round-trips. Publishing non-terminal events is not idempotent - each call creates a distinct, timestamped record. `event::completed` and `event::failed` are latched: the first terminal publication for a target returns `publish_result::applied`; every later terminal publication for that target is a no-op that returns `publish_result::already_terminal`.

Querying lifecycle state

hpx::*future*<*hpx*::*supervision*::lifecycle_state> `hpx::supervision::query_state`(*hpx*::id_type const &locality, *hpx*::id_type const &target)

hpx::*supervision*::lifecycle_state `hpx::supervision::query_state`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

hpx::*supervision*::lifecycle_state `hpx::supervision::query_state`(*hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the most recently observed lifecycle state for `target`. Includes a sequence number for gap detection and a staleness error code for remote queries whose result may lag the latest event.

Registering observers

hpx::*future*<*hpx*::id_type> `hpx::supervision::register_observer`(*hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*supervision*::lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt)

hpx::id_type `hpx::supervision::register_observer`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*supervision*::lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

hpx::id_type `hpx::supervision::register_observer`(*hpx*::id_type const &target, *hpx*::*supervision*::lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register `callback` to be invoked on lifecycle events of `target`, returning an observer handle usable with `unregister_observer`. Local callbacks fire synchronously within the publish call; remote callbacks fire via a retried parcel. If `epoch_filter` is set, the observer only receives notifications (including the initial state snapshot delivered at registration time) whose epoch matches; by default the observer receives notifications for every epoch.

Unregistering observers

hpx::*future*<void> `hpx::supervision::unregister_observer`(*hpx*::id_type const &locality, *hpx*::id_type const &observer_handle)

void `hpx::supervision::unregister_observer`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

void `hpx::supervision::unregister_observer`(*hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered observer. `observer_handle` must have been obtained from `register_observer`; a handle obtained from `register_activity_observer`, or any handle never returned by either registration function, is rejected.

Removing target state

hpx::*future*<void> `hpx::supervision::remove_target`(*hpx*::id_type const &locality, *hpx*::id_type const &target)

void `hpx::supervision::remove_target`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

void `hpx::supervision::remove_target`(*hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Clear all locally tracked state for `target`. Unlike `unregister_observer`, which removes a single previously registered observer handle, `remove_target` unconditionally forgets every piece of local state held for `target` - its recorded lifecycle state and current epoch, and any observers still registered for it - regardless of any specific observer handle. Intended for callers that know `target` will never be queried or observed again locally (e.g. after a failed registration that seeded some state for it, or once a peer has been evicted), so that local state does not accumulate indefinitely.

Waiting for terminal events

hpx::*future*<*hpx*::*supervision*::lifecycle_state> `hpx::supervision::await_terminal`(*hpx*::id_type const &locality, *hpx*::id_type const &target, *std*::uint64_t epoch = 0, *std*::chrono::steady_clock::duration timeout = *std*::chrono::steady_clock::duration::max())

hpx::*supervision*::lifecycle_state `hpx::supervision::await_terminal`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *std*::uint64_t epoch = 0, *std*::chrono::steady_clock::duration timeout = *std*::chrono::steady_clock::duration::max(), *hpx*::*error_code* &ec = *hpx*::*throws*)

hpx::*future*<*hpx*::*supervision*::lifecycle_state> `hpx::supervision::await_terminal`(*hpx*::id_type const &target, *std*::uint64_t epoch = 0, *std*::chrono::steady_clock::duration timeout = *std*::chrono::steady_clock::duration::max())

Asynchronously wait, one-shot and without blocking a worker thread, and the `launch::sync_policy` overload waits synchronously until `target` reaches a terminal event (`event::completed` or `event::failed`) within `epoch`. If a terminal event has already been recorded for `target` in `epoch`, the returned future is immediately satisfied with that state. Waits are scoped to a single epoch: if `target`'s epoch advances past `epoch` before a terminal event occurs, any outstanding waiter for the stale epoch is invalidated. A waiter that reaches neither of these outcomes is bounded by `timeout` (or a built-in default if `timeout` is left at its sentinel value `std::chrono::steady_clock::duration::max()`), after which it is swept and invalidated. Dispatch is routed locally when `target`'s supervision manager lives on the calling locality, and remotely (via a registered distributed action) otherwise.

Checking dispatch admission

hpx::*supervision*::dispatch_outcome `hpx::supervision::check_admission`(*hpx*::id_type const &target, *std*::uint64_t epoch = 0)

Check whether `target` currently admits new dispatch under `epoch`, i.e. whether it is safe to schedule or route work to it right now. This is a pure, `noexcept` local read of the same terminal latch state consulted by `await_terminal`: it returns `dispatch_outcome::rejected_fenced` if `target` has already latched a terminal event (`event::completed` or `event::failed`) under `epoch`, and `dispatch_outcome::admitted` otherwise. Unlike `publish_result`, which reports how a publication was resolved, `dispatch_outcome` answers the separate, consumer-side question of whether dispatch should proceed; it must only be called on the locality `target` lives on.

This admission fence is scoped to a single locality's latch state: it reflects only terminal events published to the supervision manager hosting `target`, and it fails open (returns `admitted`) when `target` is unknown locally, including when its terminal event was only ever published elsewhere. There is no built-in mechanism that propagates terminal latch state across localities - observer registration delivers notifications, not admission state. Any additional locality that needs to fence its own dispatch decisions on `target` must independently mirror or route to the owning locality's state; this module does not provide that for you.

Registering activity observers

hpx::*future*<*hpx*::id_type> `hpx::supervision::register_activity_observer`(*hpx*::id_type const &locality, *hpx*::*supervision*::activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt)

hpx::id_type `hpx::supervision::register_activity_observer`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::*supervision*::activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

hpx::id_type `hpx::supervision::register_activity_observer`(*hpx*::*supervision*::activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register `callback` to observe activity-state transitions (between `hpx::supervision::activity_state::inactive` and `active`) of *all* targets tracked by a locality's supervision manager. Unlike `register_observer`, none of these overloads take a `target` parameter: the feature reports on every target the addressed manager tracks rather than on a single one.

Registering an activity observer for an already-active target triggers a replay of its current state. The snapshot of tracked state and the insertion of the observer are performed atomically under the manager's internal lock, which guarantees exactly-once delivery: the observer receives either the replay or a live transition that raced with registration, but never both and never neither.

Note that the notification itself (replay or live) is delivered after the lock is released. Its delivery order relative to any other concurrent live notification for the same target is *not* guaranteed, only the exactly-once property is guaranteed, not relative ordering.

Activity notifications are a pure discovery/notification signal: unlike `publish_event`, registering or unregistering an activity observer never feeds the terminal latch consulted by `check_admission`.

If `epoch_filter` is set, `callback` only receives notifications - including the registration-time replay - whose epoch matches; by default it receives notifications regardless of epoch.

Unregistering activity observers

hpx::*future*<void> `hpx::supervision::unregister_activity_observer`(*hpx*::id_type const &locality, *hpx*::id_type const &observer_handle)

void `hpx::supervision::unregister_activity_observer`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

void `hpx::supervision::unregister_activity_observer`(*hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered activity observer. `observer_handle` must have been obtained from `register_activity_observer`; a handle obtained from `register_observer`, or any handle never returned by either registration function, is rejected.

See the *API reference* of this module for more details.

2.9 API reference

HPX follows a versioning scheme with three numbers: `major.minor.patch`. We guarantee no breaking changes in the API for patch releases. Minor releases may remove or break existing APIs, but only after a deprecation period of at least two minor releases. In rare cases do we outright remove old and unused functionality without a deprecation period.

We do not provide any ABI compatibility guarantees between any versions, debug and release builds, and builds with different C++ standards.

The public API of *HPX* is presented below. Clicking on a name brings you to the full documentation for the class or function. Including the header specified in a heading brings in the features listed under that heading.

Note

Names listed here are guaranteed stable with respect to semantic versioning. However, at the moment the list is incomplete and certain unlisted features are intended to be in the public API. While we work on completing the list, if you're unsure about whether a particular unlisted name is part of the public API you can get into contact with us or open an issue and we'll clarify the situation.

2.9.1 Public API

Our API is semantically conforming; hence, the reader is highly encouraged to refer to the corresponding facility in the C++ Standard[274] if needed. All names below are also available in the top-level `hpx` namespace unless otherwise noted. The names in `hpx` should be preferred. The names in sub-namespaces will eventually be removed.

hpx/algorithm.hpp

The header hpx/algorithm.hpp[275] corresponds to the C++ standard library header algorithm[276]. See *Using parallel algorithms* for more information about the parallel algorithms.

Classes

Table 2.126: Classes of header `hpx/algorithm.hpp`

Class	C++ standard
hpx::experimental::reduction	N4808[277]
hpx::experimental::induction	N4808[278]

Functions

Table 2.127: *hpx* functions of header `hpx/algorithm.hpp`

hpx function	C++ standard

[413] http://en.cppreference.com/w/cpp/header/any

hpx::any_nonser, *hpx::unique_any_nonser*, and their corresponding factory functions *hpx::make_any_nonser* and *hpx::make_unique_any_nonser* are *HPX* extensions that do not support serialization and have no counterparts in the C++ standard library.

Classes

Table 2.129: Classes of header hpx/any.hpp

Class	C++ standard
hpx::any	std::any[414]
hpx::any_nonser	
hpx::bad_any_cast	std::bad_any_cast[415]
hpx::unique_any_nonser	

Functions

Table 2.130: Functions of header hpx/any.hpp

Function	C++ standard
hpx::any_cast	std::any_cast[416]
hpx::make_any	std::make_any[417]
hpx::make_any_nonser	
hpx::make_unique_any_nonser	

hpx/assert.hpp

The header hpx/assert.hpp[418] corresponds to the C++ standard library header cassert[419].

HPX_ASSERT is the *HPX* equivalent to assert in cassert. HPX_ASSERT can also be used in CUDA device code.

Macros

Table 2.131: Macros of header hpx/assert.hpp

Macro
HPX_ASSERT
HPX_ASSERT_MSG

419 http://en.cppreference.com/w/cpp/header/cassert

hpx/barrier.hpp

The header hpx/barrier.hpp[420] corresponds to the C++ standard library header barrier[421] and contains a distributed barrier implementation. This functionality is also exposed through the `hpx::distributed` namespace. The name in `hpx::distributed` should be preferred.

Classes

Table 2.132: Classes of header `hpx/barrier.hpp`

Class	C++ standard
hpx::barrier	std::barrier[422]

Table 2.133: Distributed implementation of classes of header `hpx/barrier.hpp`

Class
hpx::distributed::barrier

hpx/channel.hpp

The header hpx/channel.hpp[423] contains a local and a distributed channel implementation. This functionality is also exposed through the `hpx::distributed` namespace. The name in `hpx::distributed` should be preferred.

The channel functionality is specific to *HPX* and has no counterpart in the C++ standard library.

Classes

Table 2.134: Classes of header `hpx/channel.hpp`

Class
`hpx::channel`

Table 2.135: Distributed implementation of classes of header `hpx/channel.hpp`

Class
`hpx::distributed::channel`

hpx/chrono.hpp

The header hpx/chrono.hpp[424] corresponds to the C++ standard library header chrono[425]. The following replacements and extensions are provided compared to chrono[426].

Classes

Table 2.136: Classes of header hpx/chrono.hpp

Class	C++ standard
hpx::chrono::high_resolution_clock	std::high_resolution_clock[427]
hpx::chrono::high_resolution_timer	
hpx::chrono::steady_time_point	std::time_point[428]

hpx/condition_variable.hpp

The header hpx/condition_variable.hpp[429] corresponds to the C++ standard library header condition_variable[430].

Classes

Table 2.137: Classes of header hpx/condition_variable.hpp

Class	C++ standard
hpx::condition_variable	std::condition_variable[431]
hpx::condition_variable_any	std::condition_variable_any[432]
hpx::cv_status	std::cv_status[433]

hpx/exception.hpp

The header hpx/exception.hpp[434] corresponds to the C++ standard library header exception[435]. *hpx::exception* extends `std::exception` and is the base class for all exceptions thrown in *HPX*. *HPX_THROW_EXCEPTION* can be used to throw *HPX* exceptions with file and line information attached to the exception.

[424] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/chrono.hpp

hpx::exception	std::exception[436]

hpx/execution.hpp

The header hpx/execution.hpp[437] corresponds to the C++ standard library header execution[438]. See *High level parallel facilities*, *Using parallel algorithms* and *Executor parameters and executor parameter traits* for more information about execution policies and executor parameters.

Note

These names are only available in the `hpx::execution` namespace, not in the top-level `hpx` namespace.

Constants

Table 2.139: Constants of header hpx/execution.hpp

Constant	C++ standard
hpx::execution::seq	std::execution_policy_tag[439]

hpx::execution::experimental::num_cores	

`hpx/functional.hpp`

The header hpx/functional.hpp[445] corresponds to the C++ standard library header functional[446]. *hpx::function* is a more efficient and serializable replacement for `std::function`.

Constants

The following constants correspond to the C++ standard std::placeholders[447]

Table 2.141: Constants of header `hpx/functional.hpp`

Constant
hpx::placeholders::_1
hpx::placeholders::_2
...
hpx::placeholders::_9

hpx::invoke_fused	std::apply[457]
hpx::invoke_fused_r	
hpx::mem_fn	std::mem_fn[458]

`hpx/future.hpp`

The header hpx/future.hpp[459] corresponds to the C++ standard library header future[460]. See *Extended facilities for futures* for more information about extensions to futures compared to the C++ standard library.

This header file also contains overloads of *hpx::async*, *hpx::post*, *hpx::sync*, and *hpx::dataflow* that can be used with actions. See *Action invocation* for more information about invoking actions.

hpx/numeric.hpp

The header hpx/numeric.hpp[505] corresponds to the C++ standard library header numeric[506]. See *Using parallel algorithms* for more information about the parallel algorithms.

Functions

Table 2.155: *hpx* functions of header `hpx/numeric.hpp`

hpx function	C++ standard
hpx::adjacent_difference	std::adjacent_difference[507]
hpx::exclusive_scan	std::exclusive_scan[508]
hpx::inclusive_scan	std::inclusive_scan[509]
hpx::reduce	std::reduce[510]
hpx::transform_exclusive_scan	std::transform_exclusive_scan[511]
hpx::transform_inclusive_scan	std::transform_inclusive_scan[512]
hpx::transform_reduce	std::transform_reduce[513]

Table 2.156: *hpx::ranges* functions of header `hpx/numeric.hpp`

hpx::ranges function
hpx::ranges::adjacent_difference
hpx::ranges::exclusive_scan
hpx::ranges::inclusive_scan
hpx::ranges::reduce
hpx::ranges::transform_exclusive_scan
hpx::ranges::transform_inclusive_scan
hpx::ranges::transform_reduce

hpx/optional.hpp

The header hpx/optional.hpp[514] corresponds to the C++ standard library header optional[515]. `hpx::optional` is compatible with `std::optional`.

505 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/numeric.hpp

[546] http://wg21.link/n4755

hpx/experimental/task_group.hpp

The header hpx/experimental/task_group.hpp[547] corresponds to the `task_group` feature in oneAPI Threading Building Blocks (oneTBB)[548].

Classes

Table 2.169: Classes of header `hpx/experimental/task_group.hpp`

Class
hpx::experimental::task_group

hpx/thread.hpp

The header hpx/thread.hpp[549] corresponds to the C++ standard library header thread[550]. The functionality in this header is equivalent to the standard library thread functionality, with the exception that the *HPX* equivalents are implemented on top of lightweight threads and the *HPX* runtime.

Classes

Table 2.170: Classes of header `hpx/thread.hpp`

Class	C++ standard
hpx::thread	std::thread[551]
hpx::jthread	std::jthread[552]

Functions

Table 2.171: Functions of header `hpx/thread.hpp`

Function	C++ standard
hpx::this_thread::yield	std::yield[553]
hpx::this_thread::get_id	std::get_id[554]
hpx::this_thread::sleep_for	std::sleep_for[555]
hpx::this_thread::sleep_until	std::sleep_until[556]

[547] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/experimental/task_group.hpp

[556] http://en.cppreference.com/w/cpp/thread/sleep_until

hpx/tuple.hpp

The header hpx/tuple.hpp[557] corresponds to the C++ standard library header tuple[558].
hpx::tuple can be used in CUDA device code, unlike `std::tuple`.

Constants

Table 2.172: Constants of header `hpx/tuple.hpp`

Constant	C++ standard
hpx::ignore	std::ignore[559]

Classes

Table 2.173: Classes of header `hpx/tuple.hpp`

Class	C++ standard
hpx::tuple	std::tuple[560]
hpx::tuple_size	std::tuple_size[561]
hpx::tuple_element	std::tuple_element[562]

Functions

hpx/version.hpp

The header hpx/version.hpp[573] provides version information about *HPX*.

The macros and functions provided by this header are specific to *HPX* and have no counterparts in the C++ standard library.

Macros

Table 2.178: Macros of header hpx/version.hpp

Macro
HPX_VERSION_MAJOR
HPX_VERSION_MINOR
HPX_VERSION_SUBMINOR
HPX_VERSION_FULL
HPX_VERSION_DATE
HPX_VERSION_TAG
HPX_AGAS_VERSION

Functions

hpx::subminor_version
hpx::full_version
hpx::full_version_as_string
hpx::tag
hpx::agas_version
hpx::build_type
hpx::build_date_time

hpx/wrap_main.hpp

The header hpx/wrap_main.hpp[574] does not provide any direct functionality but is used for implicitly using `main` as the runtime entry point. See *Re-use the main() function as the main HPX entry point* for more details on implicitly starting the *HPX* runtime.

573 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/version/include/hpx/version.hpp
574 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/wrap/include/hpx/wrap_main.hpp

2.9.2 Public distributed API

Our Public Distributed API offers a rich set of tools and functions that enable developers to harness the full potential of distributed computing. Here, you'll find a comprehensive list of header files, classes and functions for various distributed computing features provided by *HPX*.

hpx/barrier.hpp

The header hpx/barrier.hpp[575] includes a distributed barrier implementation. For information regarding the C++ standard library header barrier[576], see *Public API*.

Classes

Table 2.180: Distributed implementation of classes of header `hpx/barrier.hpp`

Class
hpx::distributed::barrier

Functions

Table 2.181: *hpx* functions of header `hpx/barrier.hpp`

Function
`hpx::distributed::wait`
`hpx::distributed::synchronize`

hpx/collectives.hpp

The header hpx/collectives.hpp[577] contains definitions and implementations related to the collectives operations.

575 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/barrier.hpp

hpx::collectives::communicator::is_root
hpx::collectives::exclusive_scan
hpx::collectives::gather_here
hpx::collectives::gather_there
hpx::collectives::inclusive_scan
hpx::collectives::reduce_here
hpx::collectives::reduce_there
hpx::collectives::scatter_from
hpx::collectives::scatter_to

`hpx/latch.hpp`

The header hpx/latch.hpp[578] includes a distributed latch implementation. For information regarding the C++ standard library header latch[579], see *Public API*.

Classes

Table 2.184: Distributed implementation of classes of header `hpx/latch.hpp`

Class
hpx::distributed::latch

Member functions

Table 2.185: *hpx* functions of class hpx::distributed::latch from header `hpx/latch.hpp`

Function
`hpx::distributed::latch::count_down_and_wait`
`hpx::distributed::latch::arrive_and_wait`
`hpx::distributed::latch::count_down`
`hpx::distributed::latch::is_ready`
`hpx::distributed::latch::try_wait`
`hpx::distributed::latch::wait`

`hpx/async.hpp`

The header hpx/async.hpp[580] includes distributed implementations of *hpx::async*, *hpx::post*, *hpx::sync*, and *hpx::dataflow*. For information regarding the C++ standard library header, see *Public API*.

Functions

Table 2.186: Distributed implementation of functions of header `hpx/async.hpp`

Functions
modules_hpx/async_distributed/async.hpp_api
modules_hpx/async_distributed/sync.hpp_api
modules_hpx/async_distributed/post.hpp_api
modules_hpx/async_distributed/dataflow.hpp_api

hpx/components.hpp

The header hpx/include/components.hpp[581] includes the components implementation. A component in *hpx* is a C++ class which can be created remotely and for which its member functions can be invoked remotely as well. More information about how components can be defined, created, and used can be found in *Writing components*. *Components and actions* includes examples on the accumulator, template accumulator and template function accumulator.

Macros

Function
*hpx::new_*

[581] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/include/components.hpp

hpx/supervision_dispatch.hpp

The header hpx/supervision_dispatch.hpp[582] provides peer discovery, cooperative lifecycle management, failure detection, and fenced action dispatch across localities. See *Supervision dispatch module* for the full API reference and *Supervision dispatch* for the narrative documentation.

Classes

Table 2.190: *hpx* classes of header `hpx/supervision_dispatch.hpp`

Class
hpx::supervision::registry

Functions

Table 2.191: *hpx* functions of header `hpx/supervision_dispatch.hpp`

Function
hpx::supervision::discover_and_join
hpx::supervision::dispatch_work

2.9.3 Supervision dispatch module

The supervision dispatch module provides peer discovery, cooperative lifecycle management, failure detection, and fenced action dispatch across localities, built on top of the *supervision* module's lifecycle events and admission checks. See that module's reference for the semantics of *hpx::supervision::check_admission* and `hpx::supervision::dispatch_outcome`; this page documents only the dispatch-specific surface layered on top of them. For the narrative on initialization ordering, one-shot discovery, shadow-state semantics, and client-side filtering versus fenced-dispatch admission, see *Supervision dispatch*.

Overview

[582] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/components/supervision_dispatch/include/hpx/supervision_dispatch.hpp

Functions

Table 2.192: *hpx::supervision* dispatch functions

Function	Description
hpx::supervision::init	*One-shot, idempotent runtime initialization.*
hpx::supervision::finalize	*One-shot, idempotent runtime teardown.*
hpx::supervision::is_initialized	*Whether the runtime is currently active.*
hpx::supervision::discover_peers	*One-time discovery pull across localities.*
hpx::supervision::fan_out_join	*Fan out join() calls to discovered peers.*
hpx::supervision::discover_and_join	*Composed discovery-and-join pass.*
hpx::supervision::dispatch_work	*Dispatch an action under supervision fencing.*

Types

Table 2.193: *hpx::supervision* dispatch types

Type	Description
hpx::supervision::registry	*Client handle mirroring a peer's lifecycle state.*
`hpx::supervision::server::peer_snapshot`	*Point-in-time view of a joined peer.*
`hpx::supervision::discovered_peer`	*A discovered peer with locality and join epoch.*

Lifecycle initialization and shutdown

hpx::*shared_future*<*hpx*::*supervision*::*registry*> `hpx::supervision::init`(*hpx*::chrono::steady_duration const &discovery_timeout = *hpx*::*supervision*::default_discovery_timeout)

hpx::*supervision*::*registry* `hpx::supervision::init`(*hpx*::*launch*::sync_policy, *hpx*::chrono::steady_duration const &discovery_timeout = *hpx*::*supervision*::default_discovery_timeout)

Performs one-shot, idempotent initialization of the supervision-dispatch runtime for this locality: creates a local registry, publishes `event::started` before its symbol name is registered, registers that name, and performs a single `discover_and_join()` pass. Calling `init()` while already active is a no-op; concurrent callers during `initializing` attach to the in-flight operation instead of racing it.

void `hpx::supervision::finalize`()

Performs one-shot, idempotent teardown of the runtime previously started by `init()`: publishes `event::completed` at the current/unchanged epoch, unregisters the registry's symbol name, and releases the registry. A no-op unless the runtime is currently `active`.

bool `hpx::supervision::is_initialized`() noexcept

Returns whether the runtime is currently `active`. Never blocks; safe to call from any thread, including while `init()`/`finalize()` is in flight.

Peer discovery

struct *hpx*::*supervision*::**discovered_peer**

A peer whose registry symbol name resolved during a `discover_peers()` call. Holds `locality`, `registry_client`, and `join_epoch`. `discover_peers()` leaves `join_epoch` at `hpx::supervision::unjoined_epoch` (never `0`, which is a legitimate join epoch); `fan_out_join()` fills it in with the epoch recorded by `registry::join()`. `locality` is cached for convenience but is never independently resolved or validated: it is always derived from `registry_client` itself (see `registry::get_locality()`), since exactly one registry exists per locality.

std::vector<*hpx*::*supervision*::*discovered_peer*> *hpx*::*supervision*::**discover_peers**(*hpx*::chrono::steady_duration const &timeout = *hpx*::*supervision*::default_discovery_timeout)

Performs a one-time discovery pull: concurrently resolves the pinned registry name of every remote locality, bounded by a single wait for `timeout`. Localities that have not yet called `init()` are silently excluded rather than causing a hang or failure.

std::vector<*hpx*::*supervision*::*discovered_peer*> *hpx*::*supervision*::**fan_out_join**(...)

Fans out `join()` calls from `local_registry` to every entry in `peers`. Reuses `registry::join()`'s reservation/idempotency machinery, so repeated or overlapping calls never create more than one shadow per peer locality.

Returns a `discovered_peer` for each peer whose `join()` call settled successfully within `timeout`, in the same relative order as `peers`. Peers whose `join()` call did not settle in time are omitted from the result (rather than left as gaps or defaulted entries), so the returned vector is a same-order *subset* of `peers`, not index-aligned with it.

std::vector<*hpx*::*supervision*::*discovered_peer*> *hpx*::*supervision*::**discover_and_join**(*hpx*::*supervision*::*registry* const &local_registry, *hpx*::chrono::steady_duration const &timeout = *hpx*::*supervision*::default_discovery_timeout)

Composes a single reactive discovery-and-join pass: one `discover_peers()` pull followed by one `fan_out_join()` call. Introduces no polling, timer, or repeated broadcast of its own.

Returns the same `discovered_peer` vector produced by `fan_out_join()` for the peers it discovered.

State query and event publication

hpx::*future*<*hpx*::*supervision*::lifecycle_state> `hpx::supervision::query_state`(*hpx*::*supervision*::*registry* const &handle)

hpx::*supervision*::lifecycle_state `hpx::supervision::query_state`(*hpx*::*launch*::sync_policy, *hpx*::*supervision*::*registry* const &handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

hpx::*future*<*hpx*::*supervision*::lifecycle_state> `hpx::supervision::query_state`(*hpx*::*supervision*::*registry* const &handle, *hpx*::*supervision*::*discovered_peer* const &peer)

hpx::*supervision*::lifecycle_state `hpx::supervision::query_state`(*hpx*::*launch*::sync_policy, *hpx*::*supervision*::*registry* const &handle, *hpx*::*supervision*::*discovered_peer* const &peer, *hpx*::*error_code* &ec = *hpx*::*throws*)

The self variants resolve both locality and target to `hpx::find_here()` and query it on the local locality; the peer variants resolve both locality and target from `peer.locality` instead - `handle` is accepted only for overload resolution and symmetry with the self variants, and is otherwise unused in that case. Each overload is a thin forwarder over the corresponding raw-id `query_state()` overload in *Supervision module*; see that module's reference for the fields of the returned `lifecycle_state`, including the `epoch` value useful for recovering the epoch a handle's locality was started at.

hpx::*future*<*hpx*::*supervision*::publish_result> `hpx::supervision::publish_event`(*hpx*::*supervision*::*registry* const &handle, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0)

hpx::*supervision*::publish_result `hpx::supervision::publish_event`(*hpx*::*launch*::sync_policy, *hpx*::*supervision*::*registry* const &handle, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *hpx*::*throws*)

Handle-based convenience overloads of `hpx::supervision::publish_event` that resolve both locality and target to `hpx::find_here()` instead of requiring the caller to name them explicitly. Thin forwarders over the raw-id `publish_event()` overloads in *Supervision module*. There is no peer variant: a locality publishes lifecycle events only for itself, never on behalf of a peer. The default epoch value of 0 is only correct for a locality's very first publication after init(); once the target's real epoch has advanced, 0 is stale. Callers publishing events after the initial one should first obtain the current epoch - e.g. via query_state(hpx::launch::sync, handle).epoch - and pass it explicitly."

Registry client

class *hpx*::*supervision*::**registry**

A lightweight, self-supervising client handle for pairing with peer localities; mirrors a peer's lifecycle state locally via `join()` and can itself be discovered by name in AGAS.

hpx::*future*<*hpx*::*supervision*::*joined_peer*> **join**(*hpx*::id_type const &peer_locality) const

hpx::*supervision*::*joined_peer* **join**(*hpx*::*launch*::sync_policy, *hpx*::id_type const &peer_locality, *hpx*::*error_code* &ec = *hpx*::*throws*) const

Joins a peer locality: creates (or reuses) local supervision state mirroring the peer's lifecycle. The returned `joined_peer::target` is `peer_locality` itself (not a generated local id) and is what `dispatch_work()` colocates against.

hpx::*future*<*std*::vector<*hpx*::*supervision*::*server*::*peer_snapshot*>> **snapshot_peers**() const

std::vector<*hpx*::*supervision*::*server*::*peer_snapshot*> **snapshot_peers**(*hpx*::*launch*::sync_policy, *hpx*::*error_code* &ec = *hpx*::*throws*) const

Returns a point-in-time snapshot of all fully joined, non-evicting peers.

hpx::*future*<bool> **register_name**()

bool **register_name**(*hpx*::*launch*::sync_policy, *hpx*::*error_code* &ec = *hpx*::*throws*)

hpx::*future*<*hpx*::id_type> **unregister_name**() const

hpx::id_type **unregister_name**(*hpx*::*launch*::sync_policy, *hpx*::*error_code* &ec = *hpx*::*throws*) const

struct *hpx*::*supervision*::*server*::**peer_snapshot**

Plain-data view of a single joined peer: `peer_locality` and `join_epoch`.

Fenced dispatch

template<typename **Action**, typename ...**Ts**>

decltype(auto) *hpx*::*supervision*::**dispatch_work**(*hpx*::id_type const &target, *std*::uint64_t epoch, *Ts*&&... ts)

Dispatches `Action` to `target` under supervision fencing. Performs a cheap, non-authoritative admission check on the caller's locality to short-circuit an already-known-fenced target, then dispatches to the target's own locality (via `hpx::colocated`) where an authoritative re-check against the same latch consulted by *hpx::supervision::check_admission* runs immediately before the wrapped action executes, on the same thread, closing the admission/invocation race. See *Supervision dispatch* for the full client-side-filtering versus fenced-admission narrative and worked examples.

Throws

`hpx::exception` with `hpx::error::target_fenced` if the target has latched a terminal event for `epoch` since the client-side check; the wrapped action is not invoked in that case.

Testing support

The following are declared in `hpx/supervision_dispatch/testing.hpp` and are **not** part of the stable public dispatch API; they exist solely to make unit tests for this module deterministic:

std::vector<*hpx*::*supervision*::*server*::*peer_snapshot*> *hpx*::*supervision*::testing::**local_snapshot_peers**()

void *hpx*::*supervision*::testing::**set_failure_detection_poll_timeout_for_testing**(*hpx*::chrono::steady_duration const &timeout)

hpx::id_type *hpx*::*supervision*::testing::**last_join_locality**()

void *hpx*::*supervision*::testing::**suspend_heartbeat_for_testing**()

bool *hpx*::*supervision*::testing::**failure_detection_sweep_in_flight_for_testing**()

See the *API reference* of this module for more details, and *Supervision module* for the underlying lifecycle event, admission, and dispatch-outcome semantics this module builds on.

2.9.4 Full API

The full API of *HPX* is presented below. The listings for the public API above refer to the full documentation below.

Note

Most names listed in the full API reference are implementation details or considered unstable. They are listed mostly for completeness. If there is a particular feature you think deserves being in the public API we may consider promoting it. In general we prioritize making sure features corresponding to C++ standard library features are stable and complete.

actions

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/actions/transfer_action.hpp

Defined in header hpx/actions/transfer_action.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/actions/transfer_base_action.hpp

Defined in header hpx/actions/transfer_base_action.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/actions/base_action.hpp

Defined in header hpx/actions/base_action.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/actions/actions_fwd.hpp

Defined in header hpx/actions/actions_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/actions/action_support.hpp

Defined in header hpx/actions/action_support.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

actions_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/actions_base/macros.hpp

Defined in header hpx/actions_base/macros.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

`HPX_REGISTER_ACTION_INVOCATION_COUNT`(Action)

`HPX_REGISTER_PER_ACTION_DATA_COUNTER_TYPES`(Action)

`HPX_MAKE_ACTION`(func)

`HPX_MAKE_DIRECT_ACTION`(func)

`HPX_DECLARE_ACTION`(...)

Declares an action type.

`HPX_REGISTER_ACTION_DECLARATION`(...)

Declare the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION_DECLARATION* can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to declare the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```
namespace app
{
    ␣
↪// Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        ␣
↪ // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server,
            print_greeting, print_greeting_action);
    };
}

// Declare␣
↪boilerplate code required for each of the component actions.
HPX_
↪REGISTER_ACTION_DECLARATION(app::server::print_greeting_action)
```

Example:

> **Note**
>
> This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* macros. It has to be visible in all translation units using the action, thus it is recommended to place it into the header file defining the component.

HPX_REGISTER_ACTION_DECLARATION_(...)

HPX_REGISTER_ACTION_DECLARATION_1(action)

HPX_REGISTER_ACTION(...)

Define the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.

Note

This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* or *HPX_DEFINE_PLAIN_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note

Only one of the forms of this macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID* should be used for a particular action, never both.

HPX_REGISTER_ACTION_ID(action, actionname, actionid)

Define the necessary component action boilerplate code and assign a predefined unique id to the action.

The macro *HPX_REGISTER_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

The parameter *actionname* specifies a unique name of the action to be used for serialization purposes. The second parameter has to be usable as a plain (nonqualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.

The parameter *actionid* specifies a unique integer value which will be used to represent the action during serialization.

Note

This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* or global actions *HPX_DEFINE_PLAIN_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note

Only one of the forms of this macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID* should be used for a particular action, never both.

HPX_DEFINE_COMPONENT_ACTION(...)

Registers a member function of a component as an action type with HPX.

The macro *HPX_DEFINE_COMPONENT_ACTION* can be used to register a member function of a component as an action type named *action_type*.

The parameter *component* is the type of the component exposing the member function *func* which should be associated with the newly defined action type. The parameter `action_type` is the name of the action type to register with HPX.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting() const
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting,
            print_greeting_action);
    };
}
```

Example:

The first argument must provide the type name of the component the action is defined for.

The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending '_action'. The third argument can be omitted only if the second argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name.

> **Note**
>
> The macro *HPX_DEFINE_COMPONENT_ACTION* can be used with 2 or 3 arguments. The third argument is optional.

`HPX_DEFINE_PLAIN_ACTION`(...)

Defines a plain action type.

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    //
↪ This will define the action type 'app::some_global_action' which
    // represents the function 'app::some_global_function'.
    HPX_
↪DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
```

Example:

Note

Usually this macro will not be used in user code unless the intent is to avoid defining the action_type in global namespace. Normally, the use of the macro *HPX_PLAIN_ACTION* is recommended.

Note

The macro *HPX_DEFINE_PLAIN_ACTION* can be used with 1 or 2 arguments. The second argument is optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name.

HPX_DECLARE_PLAIN_ACTION(...)

Declares a plain action type.

HPX_PLAIN_ACTION(...)

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX_PLAIN_ACTION* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *name* representing the given function. This macro additionally registers the newly define action type with HPX.

The parameter `func` is a global or free (non-member) function which should be encapsulated into a plain action. The parameter `name` is the name of the action type defined by this macro.

```
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which
// represents the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action)
```

Example:

Note

The macro *HPX_PLAIN_ACTION* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

Note

The macro *HPX_PLAIN_ACTION_ID* can be used with 1, 2, or 3 arguments. The second and third arguments are optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name. The default value for the third argument is *hpx::components::factory_state::check*.

Note

Only one of the forms of this macro *HPX_PLAIN_ACTION* or *HPX_PLAIN_ACTION_ID* should be used for a particular action, never both.

HPX_PLAIN_ACTION_ID(func, name, id)

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX_PLAIN_ACTION_ID* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *actionname* representing the given function.

The parameter *actionid* specifies a unique integer value which will be used to represent the action during serialization.

The parameter `func` is a global or free (non-member) function which should be encapsulated into a plain action. The parameter `name` is the name of the action type defined by this macro.

The second parameter has to be usable as a plain (nonqualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.

```
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which
// represents the function 'app::some_global_function'.
HPX_PLAIN_ACTION_ID(app::some_global_function, some_global_action,
    some_unique_id);
```

Example:

> **Note**
>
> The macro *HPX_PLAIN_ACTION_ID* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

> **Note**
>
> Only one of the forms of this macro *HPX_PLAIN_ACTION* or *HPX_PLAIN_ACTION_ID* should be used for a particular action, never both.

HPX_REGISTER_ACTION_FACTORY_ID(Name, Id)

hpx/actions_base/basic_action_fwd.hpp

Defined in header hpx/actions_base/basic_action_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **actions**

hpx/actions_base/reflect_annotated_actions.hpp

Defined in header hpx/actions_base/reflect_annotated_actions.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Annotation-driven HPX action registration via C++26 reflection.

Functions decorated with [[=hpx::actions::detail::remote_function{}]] are automatically discovered and registered as HPX plain actions.

Usage:

```
namespace my_app {
    [[=hpx::actions::detail::remote_function{}]]
    int compute(int x) { return x + 1; }
}
HPX_REGISTER_ANNOTATED_ACTIONS(my_app)

\warning This macro must be invoked after all annotated function
definitions in \a Ns are complete. Since C++ namespaces are open,
functions added to \a Ns after this macro is expanded will NOT be
discovered or registered.

// Then dispatch via:
hpx::async
↪<hpx::actions::reflect_action<^^my_app::compute>>(id, 42);
```

HPX_REGISTER_ACTION_DECLARATION

Defined in header hpx/components.hpp.

namespace **hpx**

namespace **agas**

struct **addressing_service**

Public Types

enum class **resolved_locality_state** : *std*::uint8_t

How a locality became known to this instance, which decides whether hpx::force_disconnect may remove it.

Values:

enumerator **connected**

Started with the application, or learned about by resolving its address. hpx::force_disconnect rejects it.

enumerator **connecting**

Connected after the application started and registered as such here, which only the console does. hpx::force_disconnect accepts it.

enumerator **disconnecting**

Claimed by an hpx::force_disconnect call that is still removing it. Further claims are rejected until the entry is erased.

Public Functions

HPX_NON_COPYABLE(*addressing_service*)

explicit **addressing_service**(*util*::*runtime_configuration* const &ini_)

~addressing_service() = default

void **bootstrap**(*parcelset*::endpoints_type const &endpoints, *util*::*runtime_configuration* &rtcfg)

void **initialize**(*std*::uint64_t rts_lva)

void **adjust_local_cache_size**(*std*::size_t) const

Adjust the size of the local AGAS Address resolution cache.

inline state **get_status**() const

inline void **set_status**(state new_state)

inline *naming*::gid_type const &**get_local_locality**(*error_code*& = *throws*) const

void **set_local_locality**(*naming*::gid_type const &g)

void **register_console**(*parcelset*::endpoints_type const &eps)

inline bool **is_bootstrap**() const

inline bool **is_console**() const

Returns whether this *addressing_service* represents the console locality.

inline bool **is_connecting**() const

Returns whether this *addressing_service* is connecting to a running application.

bool **is_connecting**(*hpx*::*naming*::gid_type const &locality) const

Return whether a locality joined while connecting.

Parameters
`locality` – The locality GID to inspect. If locality is invalid, return the connecting status of the calling locality.

Returns
`true` if the locality connected late, also while it is being removed and after it was disconnected, and `false` for a locality that started with the application.

bool **mark_connecting_locality_as_disconnecting**(*hpx*::*naming*::gid_type const &locality)

Atomically claim a connecting locality for disconnection.

Parameters
`locality` – The locality GID to claim.

Returns
`true` if this call changed the locality state from connecting to disconnecting, and `false` otherwise.

bool **mark_disconnecting_locality_as_connecting**(*hpx*::*naming*::gid_type const &locality)

Release a claim made by mark_connecting_locality_as_disconnecting.

Parameters
`locality` – The locality GID to release.

Returns
`true` if this call changed the locality state from disconnecting back to connecting, and `false` otherwise.

bool **resolve_locally_known_addresses**(*naming*::gid_type const &id, *naming*::address &addr) const

bool **register_locality**(*parcelset*::endpoints_type const &endpoints, *naming*::gid_type &prefix, *std*::uint32_t num_threads, bool is_connecting, *error_code* &ec = *throws*)

Add a locality to the runtime.

parcelset::endpoints_type const &**resolve_locality**(*naming*::gid_type const &gid, *error_code* &ec = *throws*)

Resolve a locality to its prefix.

Returns

Returns an empty vector if the locality is not registered.

bool **has_resolved_locality**(*naming*::gid_type const &gid) const

bool **unregister_locality**(*naming*::gid_type const &gid, *error_code* &ec = *throws*)

Remove a locality from the runtime.

void **remove_resolved_locality**(*naming*::gid_type const &gid)

remove given locality from locality cache

bool **get_console_locality**(*naming*::gid_type &locality, *error_code* &ec = *throws*)

Get locality locality_id of the console locality.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **locality** – [out] The locality_id value uniquely identifying the console locality. This is valid only, if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a console locality_id exists and returns *false* otherwise.

bool **get_localities**(*std*::vector<*naming*::gid_type> &locality_ids, *components*::component_type type, *error_code* &ec = *throws*) const

Query for the locality_ids of all known localities.

This function returns the locality_ids of all localities known to the AGAS server or all localities having a registered factory for a given component type.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- `locality_ids` – [out] The vector will contain the prefixes of all localities registered with the AGAS server. The returned vector holds the prefixes representing the runtime_support components of these localities.
- `type` – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_enum_type::invalid*, which will return prefixes of all localities.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline bool **get_localities**(*std*::vector<*naming*::gid_type> &locality_ids, *error_code* &ec = *throws*) const

hpx::*future*<*std*::uint32_t> **get_num_localities_async**(*components*::component_type type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*)) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

Parameters

`type` – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_type::invalid*, which will return prefixes of all localities.

Returns

A future that becomes ready with the number of matching localities.

std::uint32_t **get_num_localities**(*components*::component_type type, *error_code* &ec = *throws*) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- `type` – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_type::invalid*, which will return prefixes of all localities.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline *std*::uint32_t **`get_num_localities`**(*error_code* &ec = *throws*) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<*std*::uint32_t> **`get_num_overall_threads_async`**() const

std::uint32_t **`get_num_overall_threads`**(*error_code* &ec = *throws*) const

hpx::*future*<*std*::vector<*std*::uint32_t>> **`get_num_threads_async`**() const

std::vector<*std*::uint32_t> **`get_num_threads`**(*error_code* &ec = *throws*) const

components::component_type **`get_component_id`**(*std*::string const &name, *error_code* &ec = *throws*) const

Return a unique id usable as a component type.

This function returns the component type id associated with the given component name. If this is the first request for this component name a new unique id will be created.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `name` – [in] The component name (string) to get the component type for.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns the currently associated component type. Any error results in an exception thrown from this function.

void **iterate_types**(*iterate_types_function_type* const &f, *error_code* &ec = *throws*) const

std::string **get_component_type_name**(*components*::component_type id, *error_code* &ec = *throws*) const

inline *components*::component_type **register_factory**(*naming*::gid_type const &locality_id, *std*::string const &name, *error_code* &ec = *throws*) const

Register a factory for a specific component type.

This function allows to register a component factory for a given locality and component type.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `locality_id` – [in] The locality value uniquely identifying the given locality the factory needs to be registered for.
- `name` – [in] The component name (string) to register a factory for the given component type for.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns the currently associated component type. Any error results in an exception thrown from this function. The returned component type is the same as if the function *get_component_id* was called using the same component name.

components::component_type **register_factory**(*std*::uint32_t locality_id, *std*::string const &name, *error_code* &ec = *throws*) const

bool **get_id_range**(*std*::uint64_t count, *naming*::gid_type &lower_bound, *naming*::gid_type &upper_bound, *error_code* &ec = *throws*)

Get unique range of freely assignable global ids.

Every locality needs to be able to assign global ids to different components without having to consult the AGAS server for every id to generate. This function can be called to preallocate a range of ids usable for this purpose.

> **Note**
>
> This function assigns a range of global ids usable by the given locality for newly created components. Any of the returned global ids still has to be bound to a local address, either by calling *bind* or *bind_range*.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `count` – [in] The number of global ids to be generated.
- `lower_bound` – [out] The lower bound of the assigned id range. The returned value can be used as the first id to assign. This is valid only, if the return value of this function is true.
- `upper_bound` – [out] The upper bound of the assigned id range. The returned value can be used as the last id to assign. This is valid only, if the return value of this function is true.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

inline bool **bind_local**(*naming*::gid_type const &id, *naming*::address const &addr, *error_code* &ec = *throws*)

Bind a global address to a local address.

Every element in the HPX namespace has a unique global address (global id). This global address has to be associated with a concrete local address to be able to address an instance of a component using its global address.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> Binding a gid to a local address sets its global reference count to one.

Parameters

- **id** – [in] The global address which has to be bound to the local address.
- **addr** – [in] The local address to be bound to the global address.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true*, if this global id got associated with an local address. It returns *false* otherwise.

inline *hpx*::*future*<bool> **bind_async**(*naming*::gid_type const &id, *naming*::address const &addr, *std*::uint32_t locality_id)

inline *hpx*::*future*<bool> **bind_async**(*naming*::gid_type const &id, *naming*::address const &addr, *naming*::gid_type const &locality)

bool **bind_range_local**(*naming*::gid_type const &lower_id, *std*::uint64_t count, *naming*::address const &baseaddr, *std*::uint64_t offset, *error_code* &ec = *throws*)

Bind unique range of global ids to given base address.

Every locality needs to be able to bind global ids to different components without having to consult the AGAS server for every id to bind. This function can be called to bind a range of consecutive global ids to a range of consecutive local addresses (separated by a given *offset*).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> Binding a gid to a local address sets its global reference count to one.

Parameters

- **lower_id** – [in] The lower bound of the assigned id range. The value can be used as the first id to assign.
- **count** – [in] The number of consecutive global ids to bind starting at *lower_id*.
- **baseaddr** – [in] The local address to bind to the global id given by *lower_id*. This is the base address for all additional local addresses to bind to the remaining global ids.
- **offset** – [in] The offset to use to calculate the local addresses to be bound to the range of global ids.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true*, if the given range was successfully bound. It returns *false* otherwise.

hpx::*future*<bool> **bind_range_async**(*naming*::gid_type const &lower_id, *std*::uint64_t count, *naming*::address const &baseaddr, *std*::uint64_t offset, *naming*::gid_type const &locality)

inline *hpx*::*future*<bool> **bind_range_async**(*naming*::gid_type const &lower_id, *std*::uint64_t count, *naming*::address const &baseaddr, *std*::uint64_t offset, *std*::uint32_t locality_id)

inline bool **unbind_local**(*naming*::gid_type const &id, *error_code* &ec = *throws*)

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

> **Note**
>
> You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind_range*.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **id** – [in] The global address (id) for which the association has to be removed.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

inline bool **unbind_local**(*naming*::gid_type const &id, *naming*::address &addr, *error_code* &ec = *throws*)

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

Note

You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind_range*.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note

This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **id** – [in] The global address (id) for which the association has to be removed.
- **addr** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

inline bool **unbind_range_local**(*naming*::gid_type const &lower_id, *std*::uint64_t count, *error_code* &ec = *throws*)

Unbind the given range of global ids.

Note

You can unbind only global ids bound using the function *bind_range*. Do not use this function to unbind any of the global ids bound using *bind*.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note

This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **lower_id** – [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to *bind_range*.

- **count** – [in] The number of consecutive global ids to unbind starting at *lower_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind_range*
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

bool **unbind_range_local**(*naming*::gid_type const &lower_id, *std*::uint64_t count, *naming*::address &addr, *error_code* &ec = *throws*)

Unbind the given range of global ids.

> **Note**
>
> You can unbind only global ids bound using the function *bind_range*. Do not use this function to unbind any of the global ids bound using *bind*.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **lower_id** – [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to *bind_range*.
- **count** – [in] The number of consecutive global ids to unbind starting at *lower_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind_range*
- **addr** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call.

hpx::*future*<*naming*::address> **unbind_range_async**(*naming*::gid_type const &lower_id, *std*::uint64_t count = 1)

inline bool **is_local_address_cached**(*naming*::gid_type const &id, *error_code* &ec = *throws*)

Test whether the given address refers to a local object.

This function will test whether the given address refers to an object living on the locality of the caller.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **id** – [in] The address to test.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if the passed address refers to an object which lives on the locality of the caller.

bool **is_local_address_cached**(*naming*::gid_type const &id, *naming*::address &addr, *error_code* &ec = *throws*)

bool **is_local_address_cached**(*naming*::gid_type const &id, *naming*::address &addr, *std*::pair<bool, *components*::pinned_ptr> &r, *hpx*::*move_only_function*<*std*::pair<bool, *components*::pinned_ptr>(*naming*::address const&)> &&f, *error_code* &ec = *throws*)

bool **is_local_lva_encoded_address**(*std*::uint64_t msb) const

inline bool **resolve_local**(*naming*::gid_type const &id, *naming*::address &addr, *error_code* &ec = *throws*)

Resolve a given global address (*id*) to its associated local address.

This function returns the local address which is currently associated with the given global address (*id*).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **id** – [in] The global address (*id*) for which the associated local address should be returned.
- **addr** – [out] The local address which currently is associated with the given global address (id), this is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if the global address has been resolved successfully (there exists an association to a local address) and the associated local address has been returned. The function returns *false* if no association exists for the given global address. Any error results in an exception thrown from this function.

inline bool **resolve_local**(*hpx*::id_type const &id, *naming*::address &addr, *error_code* &ec = *throws*)

inline *naming*::address **resolve_local**(*naming*::gid_type const &id, *error_code* &ec = *throws*)

inline *naming*::address **resolve_local**(*hpx*::id_type const &id, *error_code* &ec = *throws*)

hpx::future_or_value<*naming*::address> **resolve_async**(*naming*::gid_type const &id)

inline *hpx*::future_or_value<*naming*::address> **resolve_async**(*hpx*::id_type const &id)

inline *naming*::address **resolve_full_local**(*naming*::gid_type const &id, *error_code* &ec = *throws*)

inline *naming*::address **resolve_full_local**(*hpx*::id_type const &id, *error_code* &ec = *throws*)

hpx::future_or_value<*naming*::address> **resolve_full_async**(*naming*::gid_type const &id)

inline *hpx*::future_or_value<*naming*::address> **resolve_full_async**(*hpx*::id_type const &id)

bool **resolve_cached**(*naming*::gid_type const &id, *naming*::address &addr, *error_code* &ec = *throws*) const

inline bool **resolve_cached**(*hpx*::id_type const &id, *naming*::address &addr, *error_code* &ec = *throws*)

inline bool **resolve_local**(*naming*::gid_type const *gids, *naming*::address *addrs, *std*::size_t size, *hpx*::detail::dynamic_bitset<> &locals, *error_code* &ec = *throws*)

bool **resolve_full_local**(*naming*::gid_type const *gids, *naming*::address *addrs, *std*::size_t size, *hpx*::detail::dynamic_bitset<> &locals, *error_code* &ec = *throws*)

bool **resolve_cached**(*naming*::gid_type const *gids, *naming*::address *addrs, *std*::size_t size, *hpx*::detail::dynamic_bitset<> &locals, *error_code* &ec = *throws*) const

hpx::future_or_value<*std*::int64_t> **incref_async**(*naming*::gid_type const &gid, *std*::int64_t credits = 1, *hpx*::id_type const &keep_alive = *hpx*::invalid_id)

Increment the global reference count for the given id.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **gid** – [in] The global address (id) for which the global reference count has to be incremented.
- **credits** – [in] The number of reference counts to add for the given id.
- **keep_alive** – [in] Id to keep alive (if valid)

Returns

Whether the operation was successful.

inline *std*::int64_t **incref**(*naming*::gid_type const &gid, *std*::int64_t credits = 1, *error_code* &ec = *throws*)

void **decref**(*naming*::gid_type const &id, *std*::int64_t credits = 1, *error_code* &ec = *throws*)

Decrement the global reference count for the given id.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **id** – [in] The global address (id) for which the global reference count has to be decremented.
- **credits** – [in] The number of reference counts to add for the given id.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns
The global reference count after the decrement.

hpx::*future*<*iterate_names_return_type*> **iterate_ids**(*std*::string const &pattern) const

Invoke the supplied *hpx::function* for every registered global name.

This function iterates over all registered global ids and returns every found entry matching the given name pattern. Any error results in an exception thrown (or reported) from this function.

Parameters
pattern – [in] pattern (possibly using wildcards) to match all existing entries against

bool **register_name**(*std*::string const &name, *naming*::gid_type const &id, *error_code* &ec = *throws*) const

Register a global name with a global address (id)

This function registers an association between a global name (string) and a global address (id) usable with one of the functions above (bind, unbind, and resolve).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **name** – [in] The global name (string) to be associated with the global address.
- **id** – [in] The global address (id) to be associated with the global address.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns
The function returns *true* if the global name was registered. It returns false if the global name is not registered.

hpx::*future*<bool> **register_name_async**(*std*::string const &name, *hpx*::id_type const &id) const

bool **register_name**(*std*::string const &name, *hpx*::id_type const &id, *error_code* &ec = *throws*) const

hpx::*future*<*hpx*::id_type> **unregister_name_async**(*std*::string const &name) const

Unregister a global name (release any existing association).

This function releases any existing association of the given global name with a global address (id).

Parameters

name – [in] The global name (string) for which any association with a global address (id) has to be released.

Returns

A future that becomes ready with the global id that was associated with the given name.

hpx::id_type **unregister_name**(*std*::string const &name, *error_code* &ec = *throws*) const

Unregister a global name (release any existing association)

This function releases any existing association of the given global name with a global address (id).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **name** – [in] The global name (string) for which any association with a global address (id) has to be released.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id that was associated with the given name. Any error results in an exception thrown from this function.

hpx::*future*<*hpx*::id_type> **resolve_name_async**(*std*::string const &name) const

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

Parameters

name – [in] The global name (string) for which the currently associated global address has to be retrieved.

Returns

A future holding the global id currently associated with the given global name.

hpx::id_type **resolve_name**(*std*::string const &name, *error_code* &ec = *throws*) const

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **name** – [in] The global name (string) for which the currently associated global address has to be retrieved.

- **ec** – [in,out] This represents the error status on exit. If this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id currently associated with the given global name.

future<*hpx*::id_type> **on_symbol_namespace_event**(*std*::string const &name, bool call_for_past_events = false) const

Install a listener for a given symbol namespace event.

This function installs a listener for a given symbol namespace event. It returns a future which becomes ready as a result of the listener being triggered.

> **Note**
>
> The only event type which is currently supported is *symbol_ns_bind*, i.e. the listener is triggered whenever a global id is registered with the given name.

Parameters

- **name** – [in] The global name (string) for which the given event should be triggered.
- **call_for_past_events** – [in, optional] Trigger the listener even if the given event has already happened in the past. The default for this parameter is *false*.

Returns

A future instance encapsulating the global id which is causing the registered listener to be triggered.

void **update_cache_entry**(*naming*::gid_type const &gid, *gva* const &gva, *error_code* &ec = *throws*)

> **Warning**

Warning

This function is for internal use only. It is dangerous and may break your code if you use it.

void **start_shutdown**(*error_code* &ec = *throws*)

hpx::*future*<*std*::pair<*hpx*::id_type, *naming*::address>> **begin_migration**(*hpx*::id_type const &id)

start/stop migration of an object

Returns

Current locality and address of the object to migrate

bool **end_migration**(*hpx*::id_type const &id)

std::pair<bool, *components*::pinned_ptr> **was_object_migrated**(*naming*::gid_type const &gid, *hpx*::*move_only_function*<*components*::pinned_ptr()> &&f) const

Maintain list of migrated objects.

hpx::*future*<void> **mark_as_migrated**(*naming*::gid_type const &gid, *hpx*::*move_only_function*<*std*::pair<bool, *hpx*::*future*<void>>()> &&f, bool expect_to_be_marked_as_migrating)

Mark the given object as being migrated (if the object is unpinned). Delay migration until the object is unpinned otherwise.

void **unmark_as_migrated**(*naming*::gid_type const &gid_, *hpx*::*move_only_function*<void()> &&f)

Remove the given object from the table of migrated objects.

void **pre_cache_endpoints**(*std*::vector<*parcelset*::endpoints_type> const&)

Functions

naming::gid_type **bootstrap_primary_namespace_gid**()

hpx::id_type **bootstrap_primary_namespace_id**()

namespace **server**

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

```
|-----MSB------||------LSB-----|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|

MSB        - Most significant bits (bit 64 to bit 127)
LSB        - Least significant bits (bit 0 to bit 63)
prefix     - Highest 32 bits (bit 96 to bit 127) of the MSB. Each
             locality is assigned a prefix. This creates a 96-bit
             address space for each locality.
RC      ␣
↪   - Bit 88 to bit 92 of the MSB. This is the log2 of the number
             of reference counting credits on the GID.
             Bit 93 is used by the locking scheme for gid_types.
        ␣
↪     Bit 94 is a flag which is set if the credit value is valid.
    ␣
↪        Bit 95 is a flag that is set if a GID's credit count is
             ever split (e.g. if the GID is ever passed to another
             locality).
    ␣
↪       - Bit 87 marks the gid such that it will not be stored in
             any of the AGAS caches. This is used mainly for ids
             which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The
   ␣
↪         content of these bits depends on the component type of
    ␣
↪        the underlying object. For all user-defined components,
             these bits contain a unique 88-bit number which is
             assigned sequentially for each locality. For
             \a hpx#components#component_enum_type#runtime_support
     ␣
↪       the high 24 bits are zeroed and the low 64 bits hold the
             LVA of the component.
```

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxx
    Historically unused address space reserved for future use.
xxxxxxxxxxxx0000xxxxxxxxxxxxxxxx
    Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxx
    Prefix of the bootstrap AGAS locality.
00000001000000010000000000000001
    ␣
↪Address of the primary_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000002
    Address␣
↪of the component_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000003
```

(continues on next page)

(continued from previous page)

```
 ␣
↪ Address of the symbol_namespace component on the bootstrap AGAS
   locality.
0000000100000001000000000000004
   Address␣
↪of the locality_namespace component on the bootstrap AGAS
   locality.
```

Note

The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

async_colocated

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::get_colocation_id

Defined in header hpx/runtime.hpp[583].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

[583] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/runtime.hpp

hpx::id_type **hpx::get_colocation_id**(*launch*::sync_policy, *hpx*::id_type const &id, *error_code* &ec = *throws*)

Return the id of the locality where the object referenced by the given id is currently located on.

The function *hpx::get_colocation_id()* returns the id of the locality where the given object is currently located.

See also

hpx::get_colocation_id()

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Parameters

- **id** – [in] The id of the object to locate.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<*hpx*::id_type> **hpx::get_colocation_id**(*hpx*::id_type const &id)

Asynchronously return the id of the locality where the object referenced by the given id is currently located on.

See also

hpx::get_colocation_id(launch::sync_policy)

Parameters

id – [in] The id of the object to locate.

async_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/async_distributed/trigger.hpp

Defined in header hpx/async_distributed/trigger.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **actions**

Functions

template<typename **Result**, typename **RemoteResult**, typename **F**, typename ...**Ts**>

void **trigger**(*typed_continuation*<*Result*, *RemoteResult*> &&cont, *F* &&f, *Ts*&&... vs) noexcept

Invoke *f* with the given arguments and forward its result to *cont*.

On success, the result of invoking *f* is passed to *cont.trigger_value()*. If invoking *f* throws, the exception is forwarded to the destination instead by calling *cont.trigger_error()* so that hpx::exceptions are propagated back to the client.

Parameters

- **cont** – The continuation that either the result or an exception is delivered to.
- **f** – The callable to invoke.
- **vs** – The arguments to invoke *f* with.

template<typename **Result**, typename **F**, typename ...**Ts**>

void **trigger**(*typed_continuation*<*Result*, *util*::unused_type> &&cont, *F* &&f, *Ts*&&... vs) noexcept

Invoke *f* with the given arguments and notify *cont* of completion. Overload for when the return type is "void" aka util::unused_type.

On success, *cont.trigger()* is called to signal completion. If invoking *f* throws, the exception is forwarded to the destination instead by calling *cont.trigger_error()* so that hpx::exceptions are propagated back to the client.

Parameters

- **cont** – The continuation that completion or an exception is delivered to.
- **f** – The callable to invoke.
- **vs** – The arguments to invoke *f* with.

hpx::sync (distributed)

Defined in header hpx/async.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::sync

template<typename **Action**, typename **F**, typename ...**Ts**>

auto *hpx*::**sync**(*F* &&f, *Ts*&&... ts) -> decltype(detail::sync_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *sync* runs the function *f* synchronously and returns a hpx::future that will eventually hold the result of that function call.

template<typename **Action**, typename **F**, typename ...**Ts**>

auto *hpx*::**sync**(*F* &&f, *Ts*&&... ts) -> decltype(detail::sync_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *sync* runs the function *f* synchronously and returns a hpx::future that will eventually hold the result of that function call.

Warning

hpx/async_distributed/promise.hpp

Defined in header hpx/async_distributed/promise.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **distributed**

Functions

template<typename **Result**, typename **RemoteResult**>

void **swap**(*promise*<*Result*, *RemoteResult*> &x, *promise*<*Result*, *RemoteResult*> &y) noexcept

template<typename **Result**, typename **RemoteResult**>

class **promise** : public *lcos*::detail::promise_base<*Result*, *RemoteResult*, *lcos*::detail::promise_data<*Result*>>

#include <promise.hpp> A promise can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the promise using the LCO's set_event action

A promise is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*. The *promise* allows to synchronize exactly one *thread* (the one passed during construction time).

```
// Create the promise (the expected result is a id_type)
hpx::distributed::promise<hpx::id_type> p;

// Get the associated future
future<hpx::id_type> f = p.get_future();

// initiate the action supplying the promise as a
// continuation
apply<some_action>(new continuation(p.get_id()), ...);

// Wait for the result to be returned, yielding control
// in the meantime.
hpx::id_type result = f.get();
// ...
```

> **Note**
>
> The action executed by the promise must return a value of a type convertible to the type as specified by the template parameter *RemoteResult*

Template Parameters

- **Result** – The template parameter *Result* defines the type this promise is expected to return from *promise::get*.
- **RemoteResult** – The template parameter *RemoteResult* defines the type this promise is expected to receive from the remote action.

Public Functions

promise() = default

constructs a promise object and a shared state.

template<typename **Allocator**>

inline **promise**(*std*::allocator_arg_t, *Allocator* const &a)

constructs a promise object and a shared state. The constructor uses the allocator *to* allocate the memory for the shared state.

promise(*promise* &&other) noexcept = default

constructs a new promise object and transfers ownership of the shared state of other (if any) to the newly- constructed object.

Post

other has no shared state.

~promise() = default

Abandons any shared state.

promise &**operator=**(*promise* &&other) noexcept = default

Abandons any shared state (30.6.4) and then as if promise(HPX_MOVE(other)).swap(*this).

Returns

*this.

inline void **swap**(*promise* &other) noexcept

Exchanges the shared state of *this and other.

Post

*this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

Private Types

using **base_type** = *lcos*::detail::promise_base<*Result*, *RemoteResult*, *lcos*::detail::promise_data<*Result*>>

template<>

class **promise**<void, *hpx*::*util*::unused_type> : public *lcos*::detail::promise_base<void, *hpx*::*util*::unused_type, *lcos*::detail::promise_data<void>>

Public Functions

promise() = default

constructs a promise object and a shared state.

template<typename **Allocator**>

inline **promise**(*std*::allocator_arg_t, *Allocator* const &a)

constructs a promise object and a shared state. The constructor uses the allocator *to* allocate the memory for the shared state.

promise(*promise* &&other) noexcept = default

constructs a new promise object and transfers ownership of the shared state of other (if any) to the newly- constructed object.

Post

other has no shared state.

~promise() = default

Abandons any shared state.

promise &**operator=**(*promise* &&other) noexcept = default

Abandons any shared state (30.6.4) and then as if promise(HPX_MOVE(other)).swap(*this).

Returns

*this.

inline void **swap**(*promise* &other) noexcept

Exchanges the shared state of *this and other.

Post

*this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

inline void **set_value**()

atomically stores the value r in the shared state and makes that state ready (30.6.4).

Throws

`future_error` – if its shared state already has a stored value. if shared state has no stored value exception is raised. promise_already_satisfied if its shared state already has a stored value or exception. no_state if *this has no shared state.

Private Types

using **base_type** = *lcos*::detail::promise_base<void, *hpx*::*util*::unused_type, *lcos*::detail::promise_data<void>>

namespace **std**

template<typename **R**, typename **Allocator**>

struct **uses_allocator**<*hpx*::*distributed*::*promise*<*R*>, *Allocator*> : public *std*::true_type

#include <promise.hpp> Requires: Allocator shall be an allocator (17.6.3.5)

hpx/async_distributed/bind_action.hpp

hpx::post (distributed)

Defined in header hpx/async.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::post

template<typename **F**, typename ...**Ts**>

bool *hpx*::**post**(*F* &&f, *Ts*&&... ts)

Runs the function `f` asynchronously (potentially in a separate thread which might be a part of a thread pool). This is done in a fire-and-forget manner, meaning there is no return value or way to synchronize with the function execution (it does not return an `hpx::future` that would hold the result of that function call).

`hpx::post` is particularly useful when synchronization mechanisms as heavyweight as futures are not desired, and instead, more lightweight mechanisms like latches or atomic variables are preferred. Essentially, the post function enables the launch of a new thread without the overhead of creating a future.

Note

`hpx::post` is similar to `hpx::async` but does not return a future. This is why there is no way of finding out the result/failure of the execution of this function.

template<typename **Action**, typename ...**Ts**>

bool *hpx*::**post**(*hpx*::id_type const &id, *Ts*&&... vs)

template<typename **Action**, typename **Client**, typename **Stub**, typename **Data**, typename ...**Ts**>

bool *hpx*::**post**(*components*::*client_base*<*Client*, *Stub*, *Data*> const &c, *Ts*&&... vs)

template<typename **Action**, typename **DistPolicy**, typename ...**Ts**>

bool *hpx*::**post**(*DistPolicy* const &policy, *Ts*&&... vs)

template<typename **Action**, typename **Continuation**, typename ...**Ts**>

bool *hpx*::**post**(*Continuation* &&c, *hpx*::id_type const &gid, *Ts*&&... vs)

template<typename **Action**, typename **Continuation**, typename **Client**, typename **Stub**, typename **Data**, typename ...**Ts**>

bool *hpx*::**post**(*Continuation* &&cont, *components*::*client_base*<*Client*, *Stub*, *Data*> const &c, *Ts*&&... vs)

template<typename **Action**, typename **Continuation**, typename **DistPolicy**, typename ...**Ts**>

bool *hpx*::**post**(*Continuation* &&c, *DistPolicy* const &policy, *Ts*&&... vs)

template<typename **Action**, typename **Target**, typename ...**Ts**>

bool *hpx*::**post**(*Action* &&action, *Target* &&target, *Ts*&&... ts)

The distributed implementation of `hpx::post` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID.

Template Parameters

- **Action** – The type of action instance
- **Target** – The type of target where the action should be executed
- **Ts** – The type of any additional arguments

Parameters

- **action** – The action instance to be executed
- **target** – The target where the action should be executed
- **ts** – Additional arguments

Returns

`true` if the action was successfully posted, `false` otherwise.

hpx/async_distributed/async_continue_callback.hpp

hpx/async_distributed/base_lco_with_value.hpp

Defined in header hpx/async_distributed/base_lco_with_value.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

namespace **lcos**

template<typename **Result**, typename **RemoteResult**, typename **ComponentTag**>

class **base_lco_with_value** : public *hpx*::*lcos*::*base_lco*, public *ComponentTag*

#include <base_lco_with_value.hpp> The base_lco_with_value class is the common base class for all LCO's synchronizing on a value. The *RemoteResult* template argument should be set to the type of the argument expected for the set_value action.

Template Parameters

- **RemoteResult** – The type of the result value to be carried back to the LCO instance.
- **ComponentTag** – The tag type representing the type of the component (either component_tag or managed_component_tag).

Public Types

using **wrapping_type** = detail::base_lco_wrapping_type<*ComponentTag*, *base_lco_with_value*>::type

using **base_type_holder** = *base_lco_with_value*

Public Functions

inline void **set_value_nonvirt**(*RemoteResult* &&result)

The *function* set_value_nonvirt is called whenever a *set_value_action* is applied on this LCO instance. This function just forwards to the virtual function *set_value*, which is overloaded by the derived concrete LCO.

Parameters

result – [in] The result value to be transferred from the remote operation back to this LCO instance.

inline *Result* **get_value_nonvirt**()

The *function* get_result_nonvirt is called whenever a *get_result_action* is applied on this LCO instance. This function just forwards to the virtual function *get_result*, which is overloaded by the derived concrete LCO.

HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco_with_value, set_value_nonvirt, set_value_action) HPX_DEFINE_COMPONENT_DIRECT_ACTION(base_lco_with_value

The *set_value_action* may be used to trigger any LCO instances while carrying an additional parameter of any type.

RemoteResult is taken by rvalue ref. This allows for perfect forwarding. When the action thread function is created, the values are moved into the called function. If we took it by const lvalue reference, we would disable the possibility to further move the result to the designated destination.

Parameters

RemoteResult – [in] The type of the result to be transferred back to this LCO instance.

The *get_value_action* may be used to query the value this LCO instance exposes as its 'result' value.

virtual void **disconnect**(*hpx*::id_type const&)

virtual **~base_lco**()

Destructor, needs to be virtual to allow for clean destruction of derived objects

void **set_event_nonvirt**()

The *function* set_event_nonvirt is called whenever a *set_event_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set_event*, which is overloaded by the derived concrete LCO.

void **set_exception_nonvirt**(*std*::exception_ptr const &e)

The *function* set_exception is called whenever a *set_exception_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set_exception*, which is overloaded by the derived concrete LCO.

Parameters

e – [in] The exception encapsulating the error to report to this LCO instance.

void **connect_nonvirt**(*hpx*::id_type const &id)

The *function* connect_nonvirt is called whenever a *connect_action* is applied on a instance of a LCO. This function just forwards to the virtual function *connect*, which is overloaded by the derived concrete LCO.

Parameters

id – [in] target id

void **disconnect_nonvirt**(*hpx*::id_type const &id)

The *function* disconnect_nonvirt is called whenever a *disconnect_action* is applied on a instance of a LCO. This function just forwards to the virtual function *disconnect*, which is overloaded by the derived concrete LCO.

Parameters

id – [in] target id

HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco, set_event_nonvirt, set_event_action) HPX_DEFINE_COMPONENT_DIRECT_ACTION(base_lco

Each of the exposed functions needs to be encapsulated into an action type, allowing to generate all required boilerplate code for threads, serialization, etc.

The *set_event_action* may be used to unconditionally trigger any LCO instances, it carries no additional parameters. The *set_exception_action* may be used to transfer arbitrary error information from the remote site to the LCO instance specified as a continuation. This action carries 2 parameters:

Parameters

std::exception_ptr – [in] The exception encapsulating the error to report to this LCO instance.

set_exception_action HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco, connect_nonvirt, connect_action) HPX_DEFINE_COMPONENT_DIRECT_ACTION(base_lco

The *connect_action* may be used to.

The *set_exception_action* may be used to

hpx::distributed::promise

Defined in header hpx/future.hpp[584].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Result**, typename **RemoteResult**>

class **promise** : public *hpx*::*lcos*::detail::promise_base<*Result*, *RemoteResult*, *lcos*::detail::promise_data<*Result*>>

A promise can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the promise using the LCO's set_event action

A promise is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*. The *promise* allows to synchronize exactly one *thread* (the one passed during construction time).

```
// Create the promise (the expected result is a id_type)
hpx::distributed::promise<hpx::id_type> p;

// Get the associated future
future<hpx::id_type> f = p.get_future();

// initiate the action supplying the promise as a
// continuation
apply<some_action>(new continuation(p.get_id()), ...);
```

(continues on next page)

[584] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/future.hpp

(continued from previous page)

```
// Wait for the result to be returned, yielding control
// in the meantime.
hpx::id_type result = f.get();
// ...
```

Note

The action executed by the promise must return a value of a type convertible to the type as specified by the template parameter *RemoteResult*

Template Parameters

- **Result** – The template parameter *Result* defines the type this promise is expected to return from *promise::get*.
- **RemoteResult** – The template parameter *RemoteResult* defines the type this promise is expected to receive from the remote action.

hpx/async_distributed/trigger_lco.hpp

Defined in header hpx/async_distributed/trigger_lco.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

hpx::async (distributed)

Defined in header hpx/async.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::async

template<typename **Action**, typename **F**, typename ...**Ts**>

auto *hpx*::**async**(*F* &&f, *Ts*&&... ts) -> decltype(detail::async_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *async* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a hpx::future that will eventually hold the result of that function call. If no policy is defined, *async* behaves as if it is called with policy being *hpx::launch::async* | hpx::launch::deferred. Otherwise, it calls a function *f* with arguments *ts* according to a specific launch policy.

- If the async flag is set (i.e. (policy & hpx::launch::async) != 0), then async executes the callable object f on a new thread of execution (with all thread-locals initialized) as if spawned by *hpx::thread*(std::forward<F>(f), std::forward<Ts>(ts)…), except that if the function f returns a value or throws an exception, it is stored in the shared state accessible through the *hpx::future* that async returns to the caller.
- If the deferred flag is set (i.e. (policy & hpx::launch::deferred) != 0), then async converts f and ts… the same way as by *hpx::thread* constructor, but does not spawn a new thread of execution. Instead, lazy evaluation is performed: the first call to a non-timed wait function on the *hpx::future* that async returned to the caller will cause the copy of f to be invoked (as a rvalue) with the copies of ts… (also passed as rvalues) in the current thread (which does not have to be the thread that originally called hpx::async). The result or exception is placed in the shared state associated with the future and only then it is made ready. All further accesses to the same *hpx::future* will return the result immediately.
- If neither hpx::launch::async nor hpx::launch::deferred, nor any implementation-defined policy flag is set in policy, the behavior is undefined.

  If more than one flag is set, it is implementation-defined which policy is selected. For the default (both the hpx::launch::async and hpx::launch::deferred flags are set in policy), standard recommends (but doesn't require) utilizing available concurrency, and deferring any additional tasks.

  In any case, the call to hpx::async synchronizes-with (as defined in std::memory_order) the call to f, and the completion of f is sequenced-before making the shared state ready. If the async policy is chosen, the associated thread completion synchronizes-with the successful return from the first function that is waiting on the shared state, or with the return of the last function that releases the shared state, whichever comes first. If std::decay<Function>::type or each type in std::decay<Ts>::type is not constructible from its corresponding argument, the program is ill-formed.

Parameters

- `f` – Callable object to call
- `ts` – parameters to pass to f

Returns

hpx::future referring to the shared state created by this call to *hpx::async*.

template<typename **Action**, typename **F**, typename ...**Ts**>

auto `hpx::async`(*F* &&f, *Ts*&&... ts) -> decltype(detail::async_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *async* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a hpx::future that will eventually hold the result of that function call. If no policy is defined, *async* behaves as if it is called with policy being *hpx::launch::async* | hpx::launch::deferred. Otherwise, it calls a function *f* with arguments *ts* according to a specific launch policy.

- If the async flag is set (i.e. (policy & hpx::launch::async) != 0), then async executes the callable object f on a new thread of execution (with all thread-locals initialized) as if spawned by *hpx::thread*(std::forward<F>(f), std::forward<Ts>(ts)…), except that if the function f returns a value or throws an exception, it is stored in the shared state accessible through the *hpx::future* that async returns to the caller.
- If the deferred flag is set (i.e. (policy & hpx::launch::deferred) != 0), then async converts f and ts… the same way as by *hpx::thread* constructor, but does not spawn a new thread

of execution. Instead, lazy evaluation is performed: the first call to a non-timed wait function on the *hpx::future* that async returned to the caller will cause the copy of f to be invoked (as a rvalue) with the copies of ts… (also passed as rvalues) in the current thread (which does not have to be the thread that originally called hpx::async). The result or exception is placed in the shared state associated with the future and only then it is made ready. All further accesses to the same *hpx::future* will return the result immediately.

- If neither hpx::launch::async nor hpx::launch::deferred, nor any implementation-defined policy flag is set in policy, the behavior is undefined.

  If more than one flag is set, it is implementation-defined which policy is selected. For the default (both the hpx::launch::async and hpx::launch::deferred flags are set in policy), standard recommends (but doesn't require) utilizing available concurrency, and deferring any additional tasks.

  In any case, the call to hpx::async synchronizes-with (as defined in std::memory_order) the call to f, and the completion of f is sequenced-before making the shared state ready. If the async policy is chosen, the associated thread completion synchronizes-with the successful return from the first function that is waiting on the shared state, or with the return of the last function that releases the shared state, whichever comes first. If std::decay<Function>::type or each type in std::decay<Ts>::type is not constructible from its corresponding argument, the program is ill-formed.

Parameters

- **f** – Callable object to call
- **ts** – parameters to pass to f

Returns

hpx::future referring to the shared state created by this call to *hpx::async*.

Warning

doxygenfunction: Unable to resolve function "hpx::async" with arguments (Executor&&, hpx::sycl::experimental::sycl_executor::queue_function_ptr_t<Ts…>&&, Ts&&…) in doxygen xml output for project "hpx" from directory: ../hpx_autodoc. Potential matches:

```
- template<typename Action,
↪ typename F, typename ...Ts> auto async(F &&f, Ts&&... ts)␣
↪-> decltype(detail::async_action_dispatch<Action, std::decay_
↪t<F>>::call(std::forward<F>(f), std::forward<Ts>(ts)...))
- template<typename Action, typename Target, typename␣
↪...Ts> auto async(Action &&action, Target &&target, Ts&&... ts)
- template<typename Executor, typename ...Ts> decltype(auto)␣
↪async(Executor &&exec, hpx::sycl::experimental::sycl_
↪executor::queue_function_ptr_t<Ts...> &&f, Ts&&... ts)
- template<typename␣
↪F, typename ...Ts> decltype(auto) async(F &&f, Ts&&... ts)
```

template<typename **Action**, typename **Target**, typename ...**Ts**>

auto *hpx*::**async**(*Action* &&action, *Target* &&target, *Ts*&&... ts)

The distributed implementation of `hpx::async` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID. The action executes asynchronously.

Template Parameters

- **`Action`** – The type of action instance
- **`Target`** – The type of target where the action should be executed
- **`Ts`** – The type of any additional arguments

Parameters

- **`action`** – The action instance to be executed
- **`target`** – The target where the action should be executed
- **`ts`** – Additional arguments

Returns

`hpx::future` referring to the shared state created by this call to `hpx::async`

hpx/async_distributed/trigger_lco_fwd.hpp

Defined in header hpx/async_distributed/trigger_lco_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

void **trigger_lco_event**(*hpx*::id_type id, *naming*::address &&addr, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should be triggered.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **trigger_lco_event**(*hpx*::id_type const &id, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should be triggered.

- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **trigger_lco_event**(*hpx*::id_type id, *naming*::address &&addr, *hpx*::id_type const &cont, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **trigger_lco_event**(*hpx*::id_type const &id, *hpx*::id_type const &cont, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set_lco_value**(*hpx*::id_type id, *naming*::address &&addr, *Result* &&t, bool move_credits = true)

Set the result value for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set_lco_value**(*hpx*::id_type const &id, *Result* &&t, bool move_credits = true)

Set the result value for the (managed) LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.

- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set_lco_value_unmanaged**(*hpx*::id_type const &id, *Result* &&t, bool move_credits = true)

Set the result value for the (unmanaged) LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set_lco_value**(*hpx*::id_type id, *naming*::address &&addr, *Result* &&t, *hpx*::id_type const &cont, bool move_credits = true)

Set the result value for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set_lco_value**(*hpx*::id_type const &id, *Result* &&t, *hpx*::id_type const &cont, bool move_credits = true)

Set the result value for the (managed) LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set_lco_value_unmanaged**(*hpx*::id_type const &id, *Result* &&t, *hpx*::id_type const &cont, bool move_credits = true)

Set the result value for the (unmanaged) LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set_lco_error**(*hpx*::id_type id, *naming*::address &&addr, *std*::exception_ptr const &e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set_lco_error**(*hpx*::id_type id, *naming*::address &&addr, *std*::exception_ptr &&e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **set_lco_error**(*hpx*::id_type const &id, *std*::exception_ptr const &e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **`set_lco_error`**(*hpx*::id_type const &id, *std*::exception_ptr &&e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::id_type id, *naming*::address &&addr, *std*::exception_ptr const &e, *hpx*::id_type const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::id_type id, *naming*::address &&addr, *std*::exception_ptr &&e, *hpx*::id_type const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **`set_lco_error`**(*hpx*::id_type const &id, *std*::exception_ptr const &e, *hpx*::id_type const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.

- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **set_lco_error**(*hpx*::id_type const &id, *std*::exception_ptr &&e, *hpx*::id_type const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

checkpoint

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/checkpoint/checkpoint.hpp

Defined in header hpx/checkpoint/checkpoint.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

This header defines the save_checkpoint and restore_checkpoint functions. These functions are designed to help HPX application developer's checkpoint their applications. Save_checkpoint serializes one or more objects and saves them as a byte stream. Restore_checkpoint converts the byte stream back into instances of the objects.

namespace **hpx**

namespace **util**

Functions

std::ostream &**operator<<**(*std*::ostream &ost, *checkpoint* const &ckp)

Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters

- **ost** – Output stream to write to.
- **ckp** – Checkpoint to copy from.

Returns

Operator<< returns the ostream object.

std::istream &**operator>>**(*std*::istream &ist, *checkpoint* &ckp)

Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

Parameters

- **ist** – Input stream to write from.
- **ckp** – Checkpoint to write to.

Returns

Operator>> returns the ostream object.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **save_checkpoint**(*T* &&t, *Ts*&&... ts)

Save_checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **U** – This parameter is used to make sure that T is not a launch policy or a checkpoint. This forces the compiler to choose the correct overload.

Parameters

- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **save_checkpoint**(*checkpoint* &&c, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Take a pre-initialized checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.

- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **save_checkpoint**(*hpx*::*launch* p, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Policy overload

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **save_checkpoint**(*hpx*::*launch* p, *checkpoint* &&c, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Policy overload & pre-initialized checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>

checkpoint **save_checkpoint**(*hpx*::*launch*::sync_policy sync_p, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Sync_policy overload

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **U** – This parameter is used to make sure that T is not a checkpoint. This forces the compiler to choose the correct overload.

Parameters

- **sync_p** – hpx::launch::sync_policy
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename **T**, typename ...**Ts**>

checkpoint **save_checkpoint**(*hpx*::*launch*::sync_policy sync_p, *checkpoint* &&c, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Sync_policy overload & pre-init. checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T` – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts` – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- `sync_p` – hpx::launch::sync_policy
- `c` – Takes a pre-initialized checkpoint to copy data into.
- `t` – A container to restore.
- `ts` – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **prepare_checkpoint**(*T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- `T` – A container to restore.
- `Ts` – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- `t` – A container to restore.
- `ts` – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **prepare_checkpoint**(*checkpoint* &&c, *T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- `T` – A container to restore.

- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **c** – Takes a pre-initialized checkpoint to prepare
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **prepare_checkpoint**(*hpx*::*launch* p, *T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **T**, typename ...**Ts**>

hpx::*future*<*checkpoint*> **prepare_checkpoint**(*hpx*::*launch* p, *checkpoint* &&c, *T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.

- **c** – Takes a pre-initialized checkpoint to prepare
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **T**, typename ...**Ts**>

void **restore_checkpoint**(*checkpoint* const &c, *T* &t, *Ts*&... ts)

Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save_checkpoint). Restore_checkpoint can resurrect a stored component in two ways: by passing in an instance of a component's shared_ptr or by passing in an instance of the component's client.

Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **c** – The checkpoint to restore.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Restore_checkpoint returns void.

class **checkpoint**

#include <checkpoint.hpp> Checkpoint Object

Checkpoint is the container object which is produced by save_checkpoint and is consumed by a restore_checkpoint. A checkpoint may be moved into the save_checkpoint object to write the byte stream to the pre-created checkpoint object.

Checkpoints are able to store all containers which are serializable including components.

Friends

friend class hpx::serialization::access

friend *std*::ostream &**operator<<**(*std*::ostream &ost, *checkpoint* const &ckp)

Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters

- **ost** – Output stream to write to.
- **ckp** – Checkpoint to copy from.

Returns

Operator<< returns the ostream object.

friend *std*::istream &**operator>>**(*std*::istream &ist, *checkpoint* &ckp)

Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

Parameters

- **ist** – Input stream to write from.
- **ckp** – Checkpoint to write to.

Returns

Operator>> returns the ostream object.

template<typename **T**, typename ...**Ts**>

friend void **restore_checkpoint**(*checkpoint* const &c, *T* &t, *Ts*&... ts)

Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save_checkpoint). Restore_checkpoint can resurrect a stored component in two ways: by passing in an instance of a component's shared_ptr or by passing in an instance of the component's client.

Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **c** – The checkpoint to restore.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Restore_checkpoint returns void.

inline friend bool **operator==**(*checkpoint* const &lhs, *checkpoint* const &rhs) noexcept

collectives

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::collectives::exclusive_scan

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **F**>

hpx::*future*<*std*::decay_t<*T*>> *hpx*::collectives::**exclusive_scan**(char const *basename, *T* &&result, *F* &&op, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

> **Note**
>
> This no-init overload has MPI_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

Parameters

- **basename** – The base name identifying the exclusive_scan operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root_site** – The site that is responsible for creating the exclusive_scan support object. This value is optional and defaults to '0' (zero).

Returns

For the participating site i this function returns the reduction (calculated according to the function op) of the values passed in by the participating sites 0, …, i-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the exclusive_scan operation has been completed.

template<typename **T**, typename **F**>

hpx::*future*<*std*::decay_t<*T*>> *hpx*::collectives::**exclusive_scan**(*communicator* comm, *T* &&result, *F* &&op, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

Note

This no-init overload has MPI_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

Note

This no-init overload has MPI_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

Parameters

- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to all participating sites from this call site.
- **`op`** – Reduction operation to apply to all values supplied from all participating sites
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to all participating sites from this call site.
- **`op`** – Reduction operation to apply to all values supplied from all participating sites
- **`generation`** – The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

For the participating site i this function returns the reduction (calculated according to the function op) of the values passed in by the participating sites 0, …, i-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the exclusive_scan operation has been completed.

Returns

For the participating site i this function returns a future the reduction (calculated according to the function op) of the values passed in by the participating sites 0, …, i-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the exclusive_scan operation has been completed.

- *hpx::collectives::scatter_from*

template<typename **T**>

hpx::*future*<*T*> `hpx::collectives::scatter_to`(char const *basename, *std*::vector<*T*> &&result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter_from* is executed)

Parameters

- **basename** – The base name identifying the scatter operation
- **result** – The value to transmit to the central scatter point from this call site.
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

template<typename **T**>

hpx::*future*<*T*> `hpx::collectives::scatter_to`(*communicator* comm, *std*::vector<*T*> &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter_from* is executed)

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter_from* is executed)

> **Note**
>
> The generation values from corresponding *scatter_to* and *scatter_from* have to match.

> **Note**
>
> The generation values from corresponding *scatter_to* and *scatter_from* have to match.

Parameters

- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to the central scatter point from this call site.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to the central scatter point from this call site.
- **`generation`** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

template<typename **T**>

T `hpx::collectives::`**`scatter_to`**(*hpx*::*launch*::sync_policy, char const *basename, *std*::vector<*T*> &&result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter_from* is executed)

Parameters

- **`basename`** – The base name identifying the scatter operation

- **result** – The value to transmit to the central scatter point from this call site.
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

Returns

This function returns the scattered value. It executes synchronously and directly returns the result.

template<typename **T**>

T hpx::collectives::**scatter_to**(*hpx*::*launch*::sync_policy, *communicator* comm, *std*::vector<*T*> &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter_from* is executed)

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter_from* is executed)

> **Note**
>
> The generation values from corresponding *scatter_to* and *scatter_from* have to match.

> **Note**
>
> The generation values from corresponding *scatter_to* and *scatter_from* have to match.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to the central scatter point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create_communicator*

- **result** – The value to transmit to the central scatter point from this call site.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns the scattered value. It executes synchronously and directly returns the result.

Returns

This function returns the scattered value. It executes synchronously and directly returns the result.

hpx::collectives::all_to_all

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

hpx::*future*<*std*::vector<*T*>> `hpx::collectives::all_to_all`(char const *basename, *std*::vector<*T*> &&local_result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*(), pairwise_threshold_arg threshold = pairwise_threshold_arg())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **basename** – The base name identifying the all_to_all operation
- **local_result** – A vector of values to transmit to all participating sites from this call site.
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root_site** – The site that is responsible for creating the all_to_all support object. This value is optional and defaults to '0' (zero).
- **threshold** – The fixed row-size threshold, in bytes, at or above which rows are exchanged directly between sites instead of being routed through one communicator site. Automatic selection uses sizeof(T) only for a trivially copyable T; other row types stay routed unless every site passes zero. See *pairwise_threshold_arg* for the default and the

remaining direct-exchange requirements. Successive generations using one basename may select different paths. Which path runs affects performance only, never the result.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

template<typename **T**>

hpx::*future*<*std*::vector<*T*>> `hpx::collectives::all_to_all`(*communicator* fid, *std*::vector<*T*> &&local_result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- `fid` – A communicator object returned from *create_communicator*
- `local_result` – A vector of values to transmit to all participating sites from this call site.
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- `generation` – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- `fid` – A communicator object returned from *create_communicator*
- `local_result` – A vector of values to transmit to all participating sites from this call site.
- `generation` – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

template<typename **T**>

std::vector<*T*> `hpx::collectives::all_to_all`(*hpx*::*launch*::sync_policy policy, char const *basename, *std*::vector<*T*> &&local_result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*(), pairwise_threshold_arg threshold = pairwise_threshold_arg())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the all_to_all operation
- **local_result** – A vector of values to transmit to all participating sites from this call site.
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root_site** – The site that is responsible for creating the all_to_all support object. This value is optional and defaults to '0' (zero).
- **threshold** – The fixed row-size threshold, in bytes, at or above which rows are exchanged directly between sites instead of being routed through one communicator site. Automatic selection uses sizeof(T) only for a trivially copyable T; other row types stay routed unless every site passes zero. See *pairwise_threshold_arg* for the default and the remaining direct-exchange requirements. Successive generations using one basename may select different paths. Which path runs affects performance only, never the result.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

template<typename **T**>

std::vector<*T*> `hpx::collectives::all_to_all`(*hpx*::*launch*::sync_policy policy, *communicator* fid, *std*::vector<*T*> &&local_result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- `policy` – The execution policy specifying synchronous execution.
- `fid` – A communicator object returned from *create_communicator*
- `local_result` – A vector of values to transmit to all participating sites from this call site.
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- `generation` – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- `policy` – The execution policy specifying synchronous execution.
- `fid` – A communicator object returned from *create_communicator*
- `local_result` – A vector of values to transmit to all participating sites from this call site.
- `generation` – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

hpx::collectives::inclusive_scan

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **F**>

hpx::*future*<*std*::decay_t<*T*>> *hpx*::collectives::**inclusive_scan**(char const *basename, *T* &&result, *F* &&op, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Parameters

- `basename` – The base name identifying the inclusive_scan operation
- `result` – The value to transmit to all participating sites from this call site.
- `op` – Reduction operation to apply to all values supplied from all participating sites
- `num_sites` – The number of participating sites (default: all localities).
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- `generation` – The generational counter identifying the sequence number of the inclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- `root_site` – The site that is responsible for creating the inclusive_scan support object. This value is optional and defaults to '0' (zero).

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

template<typename **T**, typename **F**>

hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::inclusive_scan`(*communicator* comm, *T* &&result, *F* &&op, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Parameters

- `comm` – A communicator object returned from *create_communicator*
- `result` – The value to transmit to all participating sites from this call site.
- `op` – Reduction operation to apply to all values supplied from all participating sites
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- `generation` – The generational counter identifying the sequence number of the inclusive_scan operation performed on the given base name. This is optional and needs to

be supplied only if the inclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the inclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

Parameters

- **basename** – The base name identifying the broadcast operation
- **local_result** – A value to transmit to all participating sites from this call site.
- **num_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed

more than once. The generation number (if given) must be a positive number greater than zero.

- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

> **Note**
>
> The generation values from corresponding *broadcast_to* and *broadcast_from* have to match.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **local_result** – A value to transmit to all participating sites from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

template<typename **T**>

hpx::*future*<*T*> `hpx::collectives::broadcast_to`(*communicator* comm, *generation_arg* generation, *T* &&local_result, *this_site_arg* this_site = *this_site_arg*())

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

> **Note**
>
> The generation values from corresponding *broadcast_to* and *broadcast_from* have to match.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **local_result** – A value to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

Returns

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

template<typename **T**>

hpx::*future*<*std*::vector<decay_t<*T*>>> `hpx::collectives::gather_here`(*communicator* comm, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Note

The generation values from corresponding *gather_here* and *gather_there* have to match.

Note

The generation values from corresponding *gather_here* and *gather_there* have to match.

Parameters

- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to the central gather point from this call site.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to the central gather point from this call site.
- **`generation`** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

hpx::collectives::gather_there

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::gather_here*

template<typename **T**>

hpx::*future*<void> `hpx::collectives::gather_there`(char const *basename, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

Parameters

- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root_site** – The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

Returns

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

template<typename **T**>

hpx::*future*<void> `hpx::collectives::gather_there`(*communicator* comm, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

> **Note**
>
> The generation values from corresponding *gather_here* and *gather_there* have to match.

> **Note**
>
> The generation values from corresponding *gather_here* and *gather_there* have to match.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

- **result** – The value to transmit to the central gather point from this call site.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

Returns

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

template<typename **T**>

void *hpx*::collectives::**gather_there**(*hpx*::*launch*::sync_policy, char const *basename, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

Parameters

- **basename** – The base name identifying the gather operation

- **result** – The value to transmit to the central gather point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root_site** – The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

template<typename **T**>

void *hpx*::collectives::**gather_there**(*hpx*::*launch*::sync_policy, *communicator* comm, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather_here* is executed)

> **Note**
>
> The generation values from corresponding *gather_here* and *gather_there* have to match.

> **Note**
>
> The generation values from corresponding *gather_here* and *gather_there* have to match.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create_communicator*

- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

hpx::lcos::spmd_block

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::lcos::define_spmd_block*

struct **spmd_block**

The class *spmd_block* defines an interface for launching multiple images while giving handles to each image to interact with the remaining images. The *define_spmd_block* function templates create multiple images of a user-defined action and launches them in a possibly separate thread. A temporary spmd block object is created and diffused to each image. The constraint for the action given to the define_spmd_block function is to accept a *spmd_block* as first parameter.

hpx::lcos::define_spmd_block

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::lcos::spmd_block*

template<typename **F**, typename ...**Args**>

hpx::*future*<void> hpx::lcos::**define_spmd_block**(*std*::string &&name, *std*::size_t images_per_locality, *F*&&, *Args*&&... args)

hpx::collectives::all_reduce

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **F**>

hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::all_reduce`(char const *basename, *T* &&result, *F* &&op, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- `basename` – The base name identifying the all_reduce operation
- `result` – The value to transmit to all participating sites from this call site.
- `op` – Reduction operation to apply to all values supplied from all participating sites
- `num_sites` – The number of participating sites (default: all localities).
- `generation` – The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- `root_site` – The site that is responsible for creating the all_reduce support object. This value is optional and defaults to '0' (zero).

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_reduce operation has been completed.

template<typename **T**, typename **F**>

hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::all_reduce`(*communicator* comm, *T* &&result, *F* &&op, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites

hpx::collectives::reduce_there

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::reduce_here*

template<typename **T**, typename **F**>

hpx::*future*<void> `hpx::collectives::`**`reduce_there`**(char const *basename, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce_here* is executed)

Parameters

- **basename** – The base name identifying the reduction operation
- **result** – A future referring to the value to transmit to the central reduction point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root_site** – The sequence number of the central reduction point (usually the locality id). This value is optional and defaults to 0.

Returns

This function returns a *future<void>*. It will become ready once the reduction operation has been completed.

template<typename **T**>

hpx::*future*<void> `hpx::collectives::reduce_there`(*communicator* comm, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce_here* is executed)

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce_here* is executed)

Note

The generation values from corresponding *reduce_here* and *reduce_there* have to match.

Note

The generation values from corresponding *reduce_here* and *reduce_there* have to match.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – A value to reduce on the central reduction point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create_communicator*
- **result** – A value to reduce on the central reduction point from this call site.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied

only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the reduce operation has been completed.

Returns

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce_here* is executed)

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce_here* is executed)

Note

The generation values from corresponding *reduce_here* and *reduce_there* have to match.

Note

The generation values from corresponding *reduce_here* and *reduce_there* have to match.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – A value to reduce on the central reduction point from this call site.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create_communicator*
- **result** – A value to reduce on the central reduction point from this call site.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

hpx::collectives::channel_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::create_channel_communicator*
- *hpx::collectives::get*
- *hpx::collectives::set*

class **channel_communicator**

A handle identifying the communication channel to use for get/set operations

hpx::collectives::create_channel_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::channel_communicator*
- *hpx::collectives::get*
- *hpx::collectives::set*

hpx::*future*<*channel_communicator*> `hpx::collectives::create_channel_communicator`(char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*())

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

> **Note**
>
> The caller must ensure that the communicator object returned by this function is kept alive (i.e., does not go out of scope) until all participating sites have successfully connected. Destroying the communicator before all sites have reached the creation point may cause the remaining sites to hang indefinitely. Consider using a barrier or similar synchronization mechanism after creating the communicator to ensure all sites are connected before allowing it to be destroyed.

Parameters

- **`basename`** – The base name identifying the collective operation
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future to a new communicator object usable with the collective operation.

channel_communicator `hpx::collectives::create_channel_communicator`(*hpx*::*launch*::sync_policy, char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*())

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

> **Note**
>
> The caller must ensure that the communicator object returned by this function is kept alive (i.e., does not go out of scope) until all participating sites have successfully connected. Destroying the communicator before all sites have reached the creation point may cause the remaining sites to hang indefinitely. Consider using a barrier or similar synchronization mechanism after creating the communicator to ensure all sites are connected before allowing it to be destroyed.

Parameters

- **basename** – The base name identifying the collective operation
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a new communicator object usable with the collective operation.

hpx::collectives::get

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::channel_communicator*
- *hpx::collectives::create_channel_communicator*
- *hpx::collectives::set*

template<typename **T**>

hpx::future<T> `hpx::collectives::get`(*channel_communicator* comm, *that_site_arg* site, *tag_arg* tag = *tag_arg*())

Send a value to the given site

This function receives a value from the given site based on the given communicator.

Parameters

- **comm** – The channel communicator object to use for the data transfer
- **site** – The source site

Returns

This function returns a future<T> that becomes ready once the data transfer operation has finished. The future will hold the received value.

hpx::collectives::set

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::channel_communicator*
- *hpx::collectives::create_channel_communicator*
- *hpx::collectives::get*

template<typename **T**>

hpx::*future*<void> `hpx::collectives::set`(*channel_communicator* comm, *that_site_arg* site, *T* &&value, *tag_arg* tag = *tag_arg*())

Send a value to the given site

This function sends a value to the given site based on the given communicator.

Parameters

- **comm** – The channel communicator object to use for the data transfer
- **site** – The destination site
- **value** – The value to send
- **tag** – The (optional) tag identifying the concrete operation

Returns

This function returns a *future<void>* that becomes ready once the data transfer operation has finished.

hpx::collectives::num_sites_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::this_site_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::num_sites_arg` = detail::argument_type<detail::num_sites_tag>

The number of participating sites (default: all localities)

hpx::collectives::this_site_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::this_site_arg` = detail::argument_type<detail::this_site_tag>

The local end of the communication channel.

hpx::collectives::that_site_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::that_site_arg` = detail::argument_type<detail::that_site_tag>

The opposite end of the communication channel.

hpx::collectives::generation_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::generation_arg` = detail::argument_type<detail::generation_tag>

The generational counter identifying the sequence number of the operation performed on the given base name. It needs to be supplied only if the operation on the given base name has to be performed more than once. It must be a positive number greater than zero. On any given communicator instance, operations that pass an explicit generation may not follow operations that used the default: the internal counter's position is no longer reliably known to the caller. The reverse transition, from explicit numbering back to the default, remains valid.

hpx::collectives::root_site_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::root_site_arg` = detail::argument_type<detail::root_site_tag, 0>

The site that is responsible for creating the support object of the operation. It defaults to '0' (zero).

hpx::collectives::tag_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::tag_arg` = detail::argument_type<detail::tag_tag, 0>

The tag identifying the concrete operation.

hpx::collectives::arity_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::arity_arg` = detail::argument_type<detail::arity_tag, 2>

The number of children each of the communication nodes is connected to (default: 2).

hpx::collectives::flat_fallback_threshold_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*

using `hpx::collectives::flat_fallback_threshold_arg` = detail::argument_type<detail::flat_fallback_threshold_tag, 16>

The site-count threshold below which a hierarchical_communicator collapses to a single flat communicator spanning all sites. At small site counts, flat collectives outperform hierarchical composition because tree-walking overhead exceeds the synchronization-depth benefit. Pass 0 to disable the fallback and always build a tree.

hpx::collectives::communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::create_communicator*
- *hpx::collectives::create_local_communicator*
- *hpx::collectives::create_hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

struct **communicator**

A communicator instance represents the list of sites that participate in a particular collective operation.

hpx::collectives::create_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_local_communicator*
- *hpx::collectives::create_hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

communicator `hpx::collectives::create_communicator`(char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Create a new communicator object usable with any collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of the collective operations (such as *all_gather*, *all_reduce*, *all_to_all*, *broadcast*, etc.).

Parameters

- `basename` – The base name identifying the collective operation
- `num_sites` – The number of participating sites (default: all localities).
- `this_site` – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- `generation` – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- `root_site` – The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

Throws

`hpx::exception` – with hpx::error::bad_parameter if *basename* is null or empty, if the (resolved) *num_sites* is zero, if the (resolved) *this_site* is not smaller than *num_sites*, or if the (resolved) *root_site* does not designate a participating site.

Returns

This function returns a new communicator object usable with the collective operation.

communicator `hpx::collectives::create_communicator`(*hpx*::*launch*::sync_policy policy, char const *basename, *num_sites_arg* num_sites, *this_site_arg* this_site, *generation_arg* generation, *root_site_arg* root_site)

hpx::collectives::create_local_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_communicator*
- *hpx::collectives::create_hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

communicator `hpx::collectives::create_local_communicator`(char const *basename, *num_sites_arg* num_sites, *this_site_arg* this_site, *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Create a new communicator object usable with any local collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of the collective operations (such as *all_gather*, *all_reduce*, *all_to_all*, *broadcast*, etc.).

Parameters

- **basename** – The base name identifying the collective operation
- **num_sites** – The number of participating sites
- **this_site** – The sequence number of this invocation (usually the sequence number of the object participating in the collective operation). This value must be in the range [0, num_sites).
- **generation** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **root_site** – The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

Throws

`hpx::exception` – with hpx::error::bad_parameter if *basename* is null or empty, if *num_sites* is unspecified or zero, if *this_site* is unspecified or not smaller than *num_sites*, or if the (resolved) *root_site* does not designate a participating site.

Returns

This function returns a new communicator object usable for all local collective operations.

communicator `hpx::collectives::create_local_communicator`(*hpx*::*launch*::sync_policy policy, char const *basename, *num_sites_arg* num_sites, *this_site_arg* this_site, *generation_arg* generation, *root_site_arg* root_site)

hpx::collectives::create_hierarchical_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_communicator*
- *hpx::collectives::create_local_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

hierarchical_communicator *hpx*::collectives::**create_hierarchical_communicator**(char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *arity_arg* arity = *arity_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*(), *flat_fallback_threshold_arg* threshold = *flat_fallback_threshold_arg*())

Create a new hierarchical communicator object usable with collective operations

This functions creates a new hierarchical_communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of a collective operation (such as *all_gather*, *all_reduce*, *all_to_all*, *broadcast*, etc.).

> **Note**
>
> The sub-communicators of a hierarchical_communicator share one generation sequence per registered name. Every hierarchical collective advances each sub-communicator it touches by exactly two internal generations per call (a single-pass collective such as *broadcast*, *gather*, *scatter* or *reduce*, and the inter-group exchange of *all_to_all*, skip the second generation in one step rather than performing a second round-trip). A single hierarchical_communicator instance may therefore be shared freely across collective operations, provided every call uses an explicit, strictly consecutive generation number

so the shared sequence stays gap-free. Because the two-phase hierarchical collectives (*all_gather*, *all_reduce*, *all_to_all*, *inclusive_scan*, *exclusive_scan* and the hierarchical *barrier*) derive their phase generations from that explicit number, they require it and reject an auto (default) generation. The non-hierarchical (flat) collectives keep supporting the default generation, falling back to the internal per-communicator counter maintained in the and_gate. Once any operation on a communicator has used that default, later operations on the same instance may no longer pass an explicit generation number: the counter's position is no longer reliably known to the caller. The reverse transition, from explicit numbering back to the default, remains valid. All participants of a single operation must use the same generation mode.

Note

Hierarchical collective overloads that return *hpx::future* may still perform internal waits while walking the communicator tree. They should not be treated as fully non-blocking: validation failures are reported through the returned exceptional future, but internal phase hand-offs can throw or block before that future is delivered.

Parameters

- **`basename`** – The base name identifying the collective operation
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`arity`** – The arity of the hierarchical tree of communicators to create for the given endpoint. The default arity is 2 and the value must be at least 2.
- **`generation`** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **`root_site`** – The site that is responsible for creating the collective support object. Hierarchical communicators currently support only site 0 as the root, which is also the default.
- **`threshold`** – The site-count threshold below which the communicator collapses to a single flat communicator spanning all sites (strict comparison: num_sites < threshold). The default is 16; pass 0 to disable the fallback and always build a tree.

Throws

`hpx::exception` – with hpx::error::bad_parameter if *basename* is null or empty, if the (resolved) *num_sites* is zero, if the (resolved) *this_site* is not smaller than *num_sites*, if the (resolved) *root_site* is not zero, or if *arity* is smaller than 2.

Returns

This function returns a new communicator object usable with the collective operation.

hpx::collectives::communicator::set_info

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_communicator*
- *hpx::collectives::create_local_communicator*
- *hpx::collectives::create_hierarchical_communicator*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

void *hpx*::collectives::*communicator*::**set_info**(*num_sites_arg* num_sites, *this_site_arg* this_site) noexcept

Store the number of used sites and the index of the current site for this communicator instance.

Parameters

- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this site (usually the locality id).

hpx::collectives::communicator::get_info

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_communicator*
- *hpx::collectives::create_local_communicator*
- *hpx::collectives::create_hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::is_root*

std::pair<*num_sites_arg*, *this_site_arg*> *hpx*::collectives::*communicator*::**get_info**() const noexcept

Retrieve the number of used sites and the index of the current site for this communicator instance.

hpx::collectives::communicator::is_root

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_communicator*
- *hpx::collectives::create_local_communicator*
- *hpx::collectives::create_hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*

bool `hpx::collectives::communicator::is_root()` const

Return whether this communicator instance represents the root site of the communication operation.

hpx::distributed::barrier

Defined in header hpx/barrier.hpp[586].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

explicit `hpx::distributed::barrier(`*std*::string const &base_name)

Creates a barrier, rank is locality id, size is number of localities

A barrier *base_name* is created. It expects that *hpx::get_num_localities()* participate and the local rank is *hpx::get_locality_id()*.

Parameters

base_name – The name of the barrier

`hpx::distributed::barrier(`*std*::string const &base_name, *std*::size_t num)

Creates a barrier with a given size, rank is locality id

A barrier *base_name* is created. It expects that *num* participate and the local rank is *hpx::get_locality_id()*.

Parameters

- **base_name** – The name of the barrier
- **num** – The number of participating threads

`hpx::distributed::barrier(`*std*::string const &base_name, *std*::size_t num, *std*::size_t rank)

Creates a barrier with a given size and rank

[586] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/barrier.hpp

A barrier *base_name* is created. It expects that *num* participate and the local rank is *rank*.

Parameters

- **base_name** – The name of the barrier
- **num** – The number of participating threads
- **rank** – The rank of the calling site for this invocation

hpx::*distributed*::**barrier**(*std*::string const &base_name, *std*::vector<*std*::size_t> const &ranks, *std*::size_t rank)

Creates a barrier with a vector of ranks

A barrier *base_name* is created. It expects that ranks.size() and the local rank is *rank* (must be contained in *ranks*).

Parameters

- **base_name** – The name of the barrier
- **ranks** – Gives a list of participating ranks (this could be derived from a list of locality ids
- **rank** – The rank of the calling site for this invocation

hpx::lcos::fold

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::lcos::fold_with_index*
- *hpx::lcos::inverse_fold*
- *hpx::lcos::inverse_fold_with_index*

components

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/components/basename_registration.hpp

Defined in header hpx/components/basename_registration.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

template<typename **Client**>

std::vector<*Client*> **find_all_from_basename**(*std*::string base_name, *std*::size_t num_ids)

Return all registered clients from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return all registered ids from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

> **Note**
>
> The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

> **Note**
>
> The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters

`Client` – The client type to return

Parameters

- `base_name` – [in] The base name for which to retrieve the registered ids.
- `num_ids` – [in] The number of registered ids to expect.
- `base_name` – [in] The base name for which to retrieve the registered ids.
- `num_ids` – [in] The number of registered ids to expect.

Returns

A list of futures representing the ids which were registered using the given base name.

Returns

A list of futures representing the ids which were registered using the given base name.

template<typename **Client**>

std::vector<*Client*> `find_all_from_basename`(*hpx*::*launch*::sync_policy policy, *std*::string base_name, *std*::size_t num_ids)

template<typename **Client**>

std::vector<*Client*> `find_from_basename`(*std*::string base_name, *std*::vector<*std*::size_t> const &ids)

Return registered clients from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Return registered ids from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

> **Note**
>
> The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

> **Note**
>
> The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters

`Client` – The client type to return

Parameters

- `base_name` – [in] The base name for which to retrieve the registered ids.
- `ids` – [in] The sequence numbers of the registered ids.
- `base_name` – [in] The base name for which to retrieve the registered ids.
- `ids` – [in] The sequence numbers of the registered ids.

Returns

A list of futures representing the ids which were registered using the given base name and sequence numbers.

Returns

A list of futures representing the ids which were registered using the given base name and sequence numbers.

template<typename `Client`>

std::vector<*Client*> `find_from_basename`(*hpx*::*launch*::sync_policy policy, *std*::string base_name, *std*::vector<*std*::size_t> const &ids)

template<typename `Client`>

Client `find_from_basename`(*std*::string base_name, *std*::size_t sequence_nr)

Return registered id from the given base name and sequence number.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

> **Note**
>
> The future embedded in the returned client object will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

> **Note**
>
> The future will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters
`Client` – The client type to return

Parameters

- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`sequence_nr`** – [in] The sequence number of the registered id.
- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`sequence_nr`** – [in] The sequence number of the registered id.

Returns
A representing the id which was registered using the given base name and sequence numbers.

Returns
A representing the id which was registered using the given base name and sequence numbers.

template<typename **Client**>

Client **find_from_basename**(*hpx*::*launch*::sync_policy policy, *std*::string base_name, *std*::size_t sequence_nr)

template<typename **Client**, typename **Stub**, typename **Data**>

hpx::*future*<bool> **register_with_basename**(*std*::string base_name, *components*::*client_base*<*Client*, *Stub*, *Data*> &client, *std*::size_t sequence_nr)

Register the id wrapped in the given client using the given base name.

The function registers the object the given client refers to using the provided base name.

> **Note**
>
> The operation will fail if the given sequence number is not unique.

Template Parameters
`Client` – The client type to register

Parameters

- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`client`** – [in] The client which should be registered using the given base name.

- **sequence_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

Returns
A future representing the result of the registration operation itself.

template<typename **Client**>

Client **unregister_with_basename**(*std*::string base_name, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Unregister the given id using the given base name.

Unregister the given base name.

The function unregisters the given ids using the provided base name.

The function unregisters the given ids using the provided base name.

Template Parameters
Client – The client type to return

Parameters

- **base_name** – [in] The base name for which to retrieve the registered ids.
- **sequence_nr** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register_with_basename* before.
- **base_name** – [in] The base name for which to retrieve the registered ids.
- **sequence_nr** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register_with_basename* before.

Returns
A future representing the result of the un-registration operation itself.

Returns
A future representing the result of the un-registration operation itself.

hpx::components::client

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Component**, typename **Data** = void>

class **client** : public *hpx*::*components*::*client_base*<*client*<*Component*, void>, *Component*, void>

The client class is a wrapper that manages a distributed component. It extends *client_base* with specific `Component` and `Data` types.

Template Parameters

- **Component** – The type of the component.

- **Data** – The type of the data associated with the client (default is void).

hpx/components/get_ptr.hpp

Defined in header hpx/components/get_ptr.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

template<typename **Component**>

hpx::*future*<*std*::shared_ptr<*Component*>> **get_ptr**(*hpx*::id_type const &id)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

> **Note**
>
> This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise, the function will raise an error.

> **Note**
>
> The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

id – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

Template Parameters

Component – The type of the server side component.

Returns

This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

template<typename **Derived**, typename **Stub**, typename **Data**>

hpx::*future*<*std*::shared_ptr<typename *components*::*client_base*<*Derived*, *Stub*, *Data*>::server_component_type>> **get_ptr**(*components*::*cl* *Stub*, *Data*> const &c)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

> **Note**
>
> This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise, the function will raise an error.

> **Note**
>
> The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

c – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.

Returns

This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

template<typename **Component**>

std::shared_ptr<*Component*> **get_ptr**(*launch*::sync_policy p, *hpx*::id_type const &id, *error_code* &ec = *throws*)

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

> **Note**
>
> This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise, the function will raise and error.

> **Note**
>
> The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **p** – [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- **id** – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Template Parameters

Component – The only template parameter has to be the type of the server side component.

Returns

This function returns the pointer to the underlying memory for the component instance with the given *id*.

template<typename **Derived**, typename **Stub**, typename **Data**>

std::shared_ptr<typename *components*::*client_base*<*Derived*, *Stub*, *Data*>::server_component_type> **get_ptr**(*launch*::sync_policy p, *components*::*client_base*<*Derived*, *Stub*, *Data*> const &c, *error_code* &ec = *throws*)

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

> **Note**
>
> This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise, the function will raise and error.

> **Note**
>
> The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

> **Note**

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **p** – [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- **c** – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns the pointer to the underlying memory for the component instance with the given *id*.

hpx/components/basename_registration_fwd.hpp

Defined in header hpx/components/basename_registration_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

hpx::*future*<bool> **register_with_basename**(*std*::string base_name, *hpx*::id_type const &id, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Register the given id using the given base name.

The function registers the given ids using the provided base name.

Note

The operation will fail if the given sequence number is not unique.

Parameters

- **base_name** – [in] The base name for which to retrieve the registered ids.
- **id** – [in] The id to register using the given base name.
- **sequence_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

Returns

A future representing the result of the registration operation itself.

bool **register_with_basename**(*hpx*::*launch*::sync_policy, *std*::string base_name, *hpx*::id_type const &id, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0), *error_code* &ec = *throws*)

hpx::*future*<bool> **register_with_basename**(*std*::string base_name, *hpx*::*future*<*hpx*::id_type> f, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Register the id wrapped in the given future using the given base name.

The function registers the object the given future refers to using the provided base name.

> **Note**
>
> The operation will fail if the given sequence number is not unique.

Parameters

- **base_name** – [in] The base name for which to retrieve the registered ids.
- **f** – [in] The future which should be registered using the given base name.
- **sequence_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

Returns

A future representing the result of the registration operation itself.

hpx::components::client_base

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Derived**, typename **Stub**, typename **Data**>

class **client_base** : public *hpx*::*components*::stub_base<ServerComponent>

This class template serves as a base class for client components, providing common functionality such as managing shared state, ID retrieval, and asynchronous operations.

Template Parameters

- **Derived** – The derived client component type.
- **Stub** – The stub type used for communication.
- **Data** – The extra data type used for additional information.

components_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::components::component

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::components::component_base*

template<typename **Component**>

class **component** : public *Component*

The *component* class wraps around a given component type, adding additional type aliases and constructors. It inherits from the specified component type.

hpx::components::component_base

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::components::component*

template<typename **Component**>

class **component_base** : public *hpx*::*components*::detail::base_component

component_base serves as a base class for components. It provides common functionality needed by components, such as address and ID retrieval. The template parameter *Component* specifies the derived component type.

Subclassed by hpx::performance_counters::base_performance_counter< test_counter >, Component, Component, Component

HPX_REGISTER_COMMANDLINE_MODULE

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

> **Warning**
>
> doxygenfunction: Cannot find function "HPX_REGISTER_COMMANDLINE_MODULE" in doxygen xml output for project "hpx" from directory: ../hpx_autodoc

hpx/components_base/component_type.hpp

Defined in header hpx/components_base/component_type.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/components_base/get_lva.hpp

Defined in header hpx/components_base/get_lva.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

template<typename **Component**, typename **Enable** = void>

struct **get_lva**

#include <get_lva.hpp> The get_lva template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function *agas::addressing_service::resolve*) to the address of the component implementing the action.

The default implementation uses the template argument *Component* to deduce the type wrapping the component implementing the action. This is used to get the needed address.

Template Parameters

Component – This is the type of the component implementing the action to execute.

Public Static Functions

static inline constexpr *Component* ***call**(*naming*::address_type lva) noexcept

void **intrusive_ptr_add_ref**(*managed_component*<*Component*, *Derived*> *p) noexcept

template<typename **Component**, typename **Derived**>

void **intrusive_ptr_release**(*managed_component*<*Component*, *Derived*> *p) noexcept

template<typename **Component**, typename **Derived**>

class **managed_component**

#include <managed_component_base.hpp> The *managed_component* template is used as an indirection layer for components allowing to gracefully handle the access to non-existing components.

Additionally, it provides memory management capabilities for the wrapping instances, and it integrates the memory management with the AGAS service. Every instance of a *managed_component* gets assigned a global id. The provided memory management allocates the *managed_component* instances from a special heap, ensuring fast allocation and avoids a full network round trip to the AGAS service for each of the allocated instances.

Template Parameters

- **Component** – Component type
- **Derived** – Most derived component type

Public Types

namespace **hpx**

namespace **components**

Variables

default_distribution_policy const **default_layout**

A predefined instance of the default *distribution_policy*. It will represent the local locality and will place all items to create here.

struct **default_distribution_policy**

#include <default_distribution_policy.hpp> This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

constexpr **default_distribution_policy**() = default

Default-construct a new instance of a default_distribution_policy. This policy will represent one locality (the local locality).

inline *default_distribution_policy* **operator()**(*std*::vector<id_type> locs) const

Create a new *default_distribution* policy representing the given set of localities.

Parameters

locs – [in] The list of localities the new instance should represent

inline *default_distribution_policy* **operator()**(id_type loc) const

Create a new *default_distribution* policy representing the given locality

Parameters

loc – [in] The locality the new instance should represent template<typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*hpx*::id_type> **create**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

Note

This function is part of the placement policy implemented by this class

Parameters

vs – [in] The arguments which will be forwarded to the constructor of the new object.

Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t count, *Ts*&&... vs) const

Create multiple objects on the localities associated by this policy instance

Note

This function is part of the placement policy implemented by this class

Parameters

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns

A future holding the list of global addresses that represent the newly created objects

template<typename **Action**, typename ...**Ts**>

inline *async_result*<*Action*>::type **async**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Callback**, typename ...**Ts**>

inline *async_result*<*Action*>::type **async_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

Note

This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Continuation**, typename ...**Ts**>

inline bool **apply**(*Continuation* &&c, *launch* policy, *Ts*&&... vs) const

> **Note**
>
> This function is part of the invocation policy implemented by this class

template<typename **Action**, typename ...**Ts**>

inline bool **apply**(*threads*::*thread_priority* priority, *Ts*&&... vs) const

template<typename **Action**, typename **Continuation**, typename **Callback**, typename ...**Ts**>

inline bool **apply_cb**(*Continuation* &&c, *launch* policy, *Callback* &&cb, *Ts*&&... vs) const

> **Note**
>
> This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Callback**, typename ...**Ts**>

inline bool **apply_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

inline *std*::size_t **get_num_localities**() const

Returns the number of associated localities for this distribution policy

> **Note**
>
> This function is part of the creation policy implemented by this class

inline *hpx*::id_type **get_next_target**() const

Returns the locality which is anticipated to be used for the next async operation

template<typename **Action**>

struct **async_result**

#include <default_distribution_policy.hpp>

> **Note**
>
> This function is part of the invocation policy implemented by this class

Public Types

using **type** = *hpx*::*future*<typename *traits*::promise_local_result<typename *hpx*::*traits*::extract_action<*Action*>::remote_result_type>::type>

hpx/distribution_policies/binpacking_distribution_policy.hpp

Defined in header hpx/distribution_policies/binpacking_distribution_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Variables

constexpr char const *const **default_binpacking_counter_name** = "/runtime{locality/total}/count/component@"

binpacking_distribution_policy const **binpacked**

A predefined instance of the binpacking *distribution_policy*. It will represent the local locality and will place all items to create here.

struct **binpacking_distribution_policy**

#include <binpacking_distribution_policy.hpp> This class specifies the parameters for a binpacking distribution policy to use for creating a given number of items on a given set of localities. The binpacking policy will distribute the new objects in a way such that each of the localities will equalize the number of overall objects of this type based on a given criteria (by default this criteria is the overall number of objects of this type).

Public Functions

inline **binpacking_distribution_policy**()

Default-construct a new instance of a binpacking_distribution_policy. This policy will represent one locality (the local locality).

inline *binpacking_distribution_policy* **operator()**(*std*::vector<id_type> const &locs, char const *perf_counter_name = *default_binpacking_counter_name*) const

Create a new *default_distribution* policy representing the given set of localities.

Parameters

- **locs** – [in] The list of localities the new instance should represent
- **perf_counter_name** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

inline *binpacking_distribution_policy* **operator()**(*std*::vector<id_type> &&locs, char const *perf_counter_name = *default_binpacking_counter_name*) const

Create a new *default_distribution* policy representing the given set of localities.

Parameters

- **locs** – [in] The list of localities the new instance should represent
- **perf_counter_name** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

inline *binpacking_distribution_policy* **operator()**(id_type const &loc, char const *perf_counter_name = *default_binpacking_counter_name*) const

Create a new *default_distribution* policy representing the given locality

Parameters

- **loc** – [in] The locality the new instance should represent
- **perf_counter_name** – [in] The name of the performance counter that should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

template<typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*hpx*::id_type> **create**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

Parameters

vs – [in] The arguments which will be forwarded to the constructor of the new object.

Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t count, *Ts*&&... vs) const

Create multiple objects on the localities associated by this policy instance

Parameters

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns

A future holding the list of global addresses which represent the newly created objects

inline *std*::string const &**get_counter_name**() const

Returns the name of the performance counter associated with this policy instance.

inline *std*::size_t **get_num_localities**() const

Returns the number of associated localities for this distribution policy

> **Note**
>
> This function is part of the creation policy implemented by this class

hpx/distribution_policies/colocating_distribution_policy.hpp

Defined in header hpx/distribution_policies/colocating_distribution_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Variables

colocating_distribution_policy const **colocated**

A predefined instance of the co-locating *distribution_policy*. It will represent the local locality and will place all items to create here.

struct **colocating_distribution_policy**

#include <colocating_distribution_policy.hpp> This class specifies the parameters for a distribution policy to use for creating a given number of items on the locality where a given object is currently placed.

Public Functions

constexpr **colocating_distribution_policy**() = default

Default-construct a new instance of a colocating_distribution_policy. This policy will represent the local locality.

inline *colocating_distribution_policy* **operator()**(id_type const &id) const

Create a new colocating_distribution_policy representing the locality where the given object is current located

Parameters

id – [in] The global address of the object with which the new instances should be colocated on

template<typename **Client**, typename **Stub**, typename **Data**>

inline *colocating_distribution_policy* **operator()**(*client_base*<*Client*, *Stub*, *Data*> const &client) const

Create a new colocating_distribution_policy representing the locality where the given object is current located

Parameters

`client` – [in] The client side representation of the object with which the new instances should be colocated on

template<typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*hpx*::id_type> **create**(*Ts*&&... vs) const

Create one object on the locality of the object this distribution policy instance is associated with

> **Note**
>
> This function is part of the placement policy implemented by this class

Parameters

`vs` – [in] The arguments which will be forwarded to the constructor of the new object.

Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t count, *Ts*&&... vs) const

Create multiple objects colocated with the object represented by this policy instance

> **Note**
>
> This function is part of the placement policy implemented by this class

Parameters

- `count` – [in] The number of objects to create
- `vs` – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns

A future holding the list of global addresses which represent the newly created objects

template<typename **Action**, typename ...**Ts**>

inline *async_result*<*Action*>::type **async**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Callback**, typename ...**Ts**>

> **Note**
>
> This function is part of the invocation policy implemented by this class

template<typename **Action**, typename ...**Ts**>

inline bool **apply**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Continuation**, typename **Callback**, typename ...**Ts**>

inline bool **apply_cb**(*Continuation* &&c, *launch* policy, *Callback* &&cb, *Ts*&&... vs) const

> **Note**
>
> This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Callback**, typename ...**Ts**>

inline bool **apply_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

inline *hpx*::id_type **get_next_target**() const

Returns the locality which is anticipated to be used for the next async operation

Public Static Functions

static inline *std*::size_t **get_num_localities**()

Returns the number of associated localities for this distribution policy

> **Note**
>
> This function is part of the creation policy implemented by this class

Private Functions

inline *hpx*::id_type **resolve_direct_target**() const

template<typename **Action**>

struct **async_result**

#include <colocating_distribution_policy.hpp>

> **Note**
>
> This function is part of the invocation policy implemented by this class

Public Types

using **type** = *hpx*::*future*<typename *traits*::promise_local_result<typename *hpx*::*traits*::extract_action<*Action*>::remote_result_type>::type>

hpx/distribution_policies/target_distribution_policy.hpp

Defined in header hpx/distribution_policies/target_distribution_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Variables

target_distribution_policy const **target**

A predefined instance of the target_distribution_policy. It will represent the local locality and will place all items to create here.

struct **target_distribution_policy**

#include <target_distribution_policy.hpp> This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

target_distribution_policy() = default

Default-construct a new instance of a target_distribution_policy. This policy will represent one locality (the local locality).

inline *target_distribution_policy* **operator()**(id_type const &id) const

Create a new target_distribution_policy representing the given locality

Parameters

loc – [in] The locality the new instance should represent

template<typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*hpx*::id_type> **create**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

> **Note**
>
> This function is part of the placement policy implemented by this class

Parameters

vs – [in] The arguments which will be forwarded to the constructor of the new object.

Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>

inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t count, *Ts*&&... vs) const

Create multiple objects on the localities associated by this policy instance

> **Note**
>
> This function is part of the placement policy implemented by this class

Parameters

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns

A future holding the list of global addresses which represent the newly created objects

template<typename **Action**, typename ...**Ts**>

inline *async_result*<*Action*>::type **async**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Callback**, typename ...**Ts**>

template<typename **Action**, typename ...**Ts**>

inline bool **apply**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Continuation**, typename **Callback**, typename ...**Ts**>

inline bool **apply_cb**(*Continuation* &&c, *launch* policy, *Callback* &&cb, *Ts*&&... vs) const

> **Note**
>
> This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Callback**, typename ...**Ts**>

inline bool **apply_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

inline *std*::size_t **get_num_localities**() const

Returns the number of associated localities for this distribution policy

> **Note**
>
> This function is part of the creation policy implemented by this class

inline *hpx*::id_type **get_next_target**() const

Returns the locality which is anticipated to be used for the next async operation

template<typename **Action**>

struct **async_result**

#include <target_distribution_policy.hpp>

> **Note**
>
> This function is part of the invocation policy implemented by this class

Public Types

using **type** = *hpx*::*future*<typename *traits*::promise_local_result<typename *hpx*::*traits*::extract_action<*Action*>::remote_result_type>::type>

execution_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/execution_distributed/distributed_continues_on_sender.hpp

Defined in header hpx/execution_distributed/distributed_continues_on_sender.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Placeholder for the distributed continues_on sender adaptor.

A proper component-based receiver marshalling system (nvexec-style) will be implemented here in a future phase.

hpx/execution_distributed/distributed_scheduler.hpp

Defined in header hpx/execution_distributed/distributed_scheduler.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

P2300-compliant scheduler for cross-locality execution.

Provides a scheduler that dispatches work to a remote HPX locality via the parcelport, bridging the hpx::future completion back into the P2300 set_value / set_error receiver protocol.

Usage:

```
hpx::id_type remote = hpx::find_all_localities()[1];
auto sched = hpx::distributed::distributed_scheduler{remote};
auto result = ex::just(42)
```

(continues on next page)

(continued from previous page)

```
    | ex::continues_on(sched)
    | ex::then([](int x){ return x * 2; })
    | tt::sync_wait();
```

hpx/execution_distributed/distributed_bulk_sender.hpp

Defined in header hpx/execution_distributed/distributed_bulk_sender.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

P2300-compliant distributed bulk sender adaptor.

Provides a bulk sender that executes data-parallel work on a remote HPX locality via the distributed_scheduler. The sender intercepts ex::bulk() when the upstream sender's completion scheduler is a distributed_scheduler, and dispatches a shape-indexed invocation across the parcelport.

Architecture: upstream_sender | v ex::bulk(shape, f) | (completion scheduler == distributed_scheduler) v distributed_bulk_sender<Sender, Shape, F> | v (connect + start) local_receiver wraps downstream_receiver | set_value(Ts…) | => for each index in shape: invoke f(index, ts…) | => forward set_value(ts…) to downstream v downstream_receiver

> **Note**
>
> **Current status: local-only stub.** The bulk loop executes sequentially on the calling locality. Remote parcelport dispatch will be added once the component-based receiver marshalling infrastructure (nvexec-style) is complete.

hpx/execution_distributed/distributed_then_sender.hpp

Defined in header hpx/execution_distributed/distributed_then_sender.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Placeholder for the distributed then sender adaptor.

A proper component-based receiver marshalling system (nvexec-style) will be implemented here in a future phase.

executors_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/executors_distributed/distribution_policy_executor.hpp

Defined in header hpx/executors_distributed/distribution_policy_executor.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

Functions

template<typename **DistPolicy**>

distribution_policy_executor(*DistPolicy*&&) -> *distribution_policy_executor*<*std*::decay_t<*DistPolicy*>>

```
template<typename DistPolicy>  HPX_DEPRECATED_V (1, 9,
"hpx::parallel::execution::make_distribution_policy_executor is " "deprecated,
use " "hpx::parallel::execution::distribution_policy_executor instead") distribution_policy_executor< std
```

Create a new *distribution_policy_executor* from the given distribution_policy.

Parameters

`policy` – The distribution_policy to create an executor from

template<typename **DistPolicy**>

class **distribution_policy_executor**

#include <distribution_policy_executor.hpp> A distribution_policy_executor creates groups of parallel execution agents that execute in threads implicitly created by the executor and placed on any of the associated localities.

Template Parameters

`DistPolicy` – The distribution policy type for which an executor should be created. The expression *hpx::traits::is_distribution_policy_v<DistPolicy>* must evaluate to true.

include

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/experimental/sandbox.hpp

Defined in header hpx/experimental/sandbox.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **experimental**

namespace **sandbox**

Functions

environment_info **detect_environment**()

Detect and return information about the current environment.

inline void **describe_environment**(*std*::ostream &os)

Print a formatted environment report.

template<typename **F**>

double **measure**(*F* &&fn, *std*::size_t iterations = 5)

Measure the mean execution time of a callable.

template<typename **SeqFn**, typename **ParFn**>

benchmark_report **benchmark**(*std*::string label, *SeqFn* &&seq_fn, *ParFn* &&par_fn, *std*::size_t iterations = 5)

Compare sequential and parallel execution of the same work.

struct **environment_info**

#include <sandbox.hpp> Describes the hardware and runtime environment.

Public Functions

void **print**(*std*::ostream &os) const

Print a formatted environment report.

Parameters

os – Output stream.

Public Members

std::size_t **cores** = 0

Physical CPU cores.

std::size_t **pus** = 0

Processing units (hardware threads)

std::size_t **numa_nodes** = 0

NUMA domains.

std::size_t **hpx_workers** = 0

Active HPX worker threads.

bool **is_sandbox** = false

Likely constrained environment.

struct **benchmark_report**

#include <*sandbox.hpp*> Holds the results of a comparative benchmark.

Public Functions

void **print**(*std*::ostream &os) const

Print a formatted benchmark report.

Parameters

os – Output stream.

Public Members

std::string **label**

User-provided description.

std::size_t **iterations** = 0

Measurement iterations.

double **seq_mean_ms** = 0.0

Sequential mean time (ms)

double **par_mean_ms** = 0.0

Parallel mean time (ms)

double **speedup** = 0.0

seq_time / par_time

double **efficiency_pct** = 0.0

(speedup / workers) * 100

std::size_t **num_workers** = 0

HPX workers during measurement.

init_runtime

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/hpx_start.hpp

Defined in header hpx/hpx_start.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

hpx::init_params

Defined in header hpx/init.hpp[587].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **init_params**

Parameters used to initialize the HPX runtime through hpx::init and hpx::start.

[587] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/init_runtime/include/hpx/init.hpp

hpx/hpx_init.hpp

Defined in header hpx/hpx_init.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

hpx::suspend

Defined in header hpx/init.hpp[588].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::resume*

int *hpx*::**suspend**(*error_code* &ec = *throws*)

Suspend the runtime system.

The function hpx::suspend is used to suspend the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be empty. This function only be called when the runtime is running, or already suspended in which case this function will do nothing.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Parameters

ec – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

hpx::resume

Defined in header hpx/init.hpp[589].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::suspend*

[588] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/init_runtime/include/hpx/init.hpp
[589] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/init_runtime/include/hpx/init.hpp

int `hpx::resume`(*error_code* &ec = *throws*)

Resume the HPX runtime system.

The function hpx::resume is used to resume the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be resumed. This function only be called when the runtime suspended, or already running in which case this function will do nothing.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

hpx::finalize

Defined in header hpx/init.hpp[590].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::disconnect*

int `hpx::finalize`(double shutdown_timeout, double localwait = -1.0, *hpx*::*error_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function hpx::finalize is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on all localities.

The default value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter `hpx.shutdown_timeout`), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The default value (`-1.0`) will try to find a globally set wait time value (can be set as the configuration parameter "hpx.finalize_wait_time"), and if this is not set or `-1.0` as well, it will disable any addition local wait time before proceeding.

[590] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/init_runtime/include/hpx/init.hpp

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Using this function is an alternative to hpx::disconnect, these functions do not need to be called both.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

- **shutdown_timeout** – This parameter allows to specify a timeout (in microseconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **localwait** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

inline int `hpx::finalize`(*hpx*::*error_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function hpx::finalize is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on all localities.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Using this function is an alternative to hpx::disconnect, these functions do not need to be called both.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of

hpx::exception.

Parameters

ec – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

hpx::disconnect

Defined in header hpx/init.hpp[591].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::finalize*

int *hpx*::**disconnect**(double shutdown_timeout, double localwait = -1.0, *hpx*::*error_code* &ec = *throws*)

Disconnect this locality from the application.

The function hpx::disconnect can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on this locality.

The default value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter "hpx.shutdown_timeout"), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The default value (`-1.0`) will try to find a globally set wait time value (can be set as the configuration parameter `hpx.finalize_wait_time`), and if this is not set or `-1.0` as well, it will disable any addition local wait time before proceeding.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

[591] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/init_runtime/include/hpx/init.hpp

- **`shutdown_timeout`** – This parameter allows to specify a timeout (in microseconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **`localwait`** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

inline int *hpx*::**disconnect**(*hpx*::*error_code* &ec = *throws*)

Disconnect this locality from the application.

The function hpx::disconnect can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on this locality.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero if successful, -1 otherwise.

int *hpx*::**disconnect**([[maybe_unused]] double shutdown_timeout, [[maybe_unused]] double localwait, [[maybe_unused]] *error_code* &ec)

hpx::init

Defined in header hpx/init.hpp[592].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

inline int *hpx*::**init**(*std*::function<int(*hpx*::program_options::variables_map&)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from the user supplied `f`.

inline int *hpx*::**init**(*std*::function<int(int, char**)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

[592] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/init_runtime/include/hpx/init.hpp

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **`f`** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **`argc`** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **`argv`** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **`params`** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from the user supplied `f`.

inline int *hpx*::**init**(int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. This overload expects a user-defined function named `hpx_main` at global scope, which will be used as the entry point for the HPX application.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **`argc`** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).

- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns
The function returns the value, which has been returned from `hpx_main` (or 0 when executed in worker mode).

inline int *hpx*::**init**(*std*::nullptr_t f, int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns
The function returns the value, which has been returned from the user supplied `f`.

inline int *hpx*::**init**(*init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings). This overload expects a user-defined function named `hpx_main` at global scope, which will be used as the entry point for the HPX application.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

> **Note**
>
> The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. If not command line arguments are passed, console mode is assumed.

> **Note**
>
> If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

Parameters

params – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from `hpx_main` (or 0 when executed in worker mode).

hpx::start

Defined in header hpx/init.hpp[593].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

inline bool ***hpx*::start**(*std*::function<int(*hpx*::program_options::variables_map&)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution. This overload will not call `hpx_main`.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

[593] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/init_runtime/include/hpx/init.hpp

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the hpx::start function (See documentation of hpx::init_params)

Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

inline bool `hpx::start`(*std*::function<int(int, char**)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution. This overload will not call `hpx_main`.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

> **Note**

Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

inline bool *hpx*::**start**(*init_params* const &params = *init_params*())

Main non-blocking entry point for launching the HPX runtime system.

This is a simplified main, non-blocking entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings). It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

Note

The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. If not command line arguments are passed, console mode is assumed.

Note

If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

Parameters

params – [in] The parameters to the hpx::start function (See documentation of hpx::init_params)

Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

naming_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/naming_base/unmanaged.hpp

Defined in header hpx/naming_base/unmanaged.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

hpx::id_type **unmanaged**(*hpx*::id_type const &id)

The helper function *hpx::unmanaged* can be used to generate a global identifier which does not participate in the automatic garbage collection.

Note

This function allows to apply certain optimizations to the process of memory management in HPX. It however requires the user to take full responsibility for keeping the referenced objects alive long enough.

Parameters

`id` – [in] The id to generated the unmanaged global id from This parameter can be itself a managed or a unmanaged global id.

Returns

This function returns a new global id referencing the same object as the parameter *id*. The only difference is that the returned global identifier does not participate in the automatic garbage collection.

namespace **naming**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **plugins**

template<typename **Plugin**, char const *const **Name**, char const *const **Section**, char const *const **Suffix**>

struct **plugin_registry** : public *plugin_registry_base*

#include <plugin_registry.hpp> The plugin_registry provides a minimal implementation of a plugin's registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a plugin's registry instance.

Template Parameters

Plugin – The plugin type this registry should be responsible for.

Public Functions

inline bool **get_plugin_info**(*std*::vector<*std*::string> &fillini) override

Return the ini-information for all contained components.

Parameters

fillini – [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

hpx/plugin_factories/parcelport_factory.hpp

Defined in header hpx/plugin_factories/parcelport_factory.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/plugin_factories/binary_filter_factory.hpp

Defined in header hpx/plugin_factories/binary_filter_factory.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **plugins**

template<typename **BinaryFilter**>

struct **binary_filter_factory** : public binary_filter_factory_base

#include <binary_filter_factory.hpp> The *message_handler_factory* provides a minimal implementation of a message handler's factory. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a message handler's factory instance.

Template Parameters

BinaryFilter – The message handler type this factory should be responsible for.

Public Functions

inline **binary_filter_factory**(*util*::section const *global, *util*::section const *local, bool isenabled)

Construct a new factory instance.

> **Note**
>
> The contents of both sections has to be cloned in order to save the configuration setting for later use.

Parameters

- **global** – [in] The pointer to a *hpx::util::section* instance referencing the settings read from the [settings] section of the global configuration file (hpx.ini) This pointer may be nullptr if no such section has been found.
- **local** – [in] The pointer to a *hpx::util::section* instance referencing the settings read from the section describing this component type: [hpx.components.<name>], where <name> is the instance name of the component as given in the configuration files.
- **isenabled** –

~binary_filter_factory() override = default

inline *serialization*::binary_filter ***create**(bool compress, *serialization*::binary_filter *next_filter = nullptr) override

Create a new instance of a message handler

return Returns the newly created instance of the message handler supported by this factory

Protected Attributes

util::section **global_settings_**

util::section **local_settings_**

bool **isenabled_**

resiliency_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/resiliency_distributed/async_replay_distributed.hpp

Defined in header hpx/resiliency_distributed/async_replay_distributed.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resiliency**

namespace **experimental**

Functions

template<typename **Action**, typename ...**Ts**>

hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*Action*, *hpx*::id_type, *Ts*...>> **hpx_invoke**(*async_replay_t*, *std*::vector<*hpx*::id_type> const &ids, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replay CPO.

Asynchronously launches *action* on localities in *ids*, replaying on the next locality on error (aborts on abort_replay_exception).

Parameters

- **tag** – CPO tag (async_replay_t).
- **ids** – Target localities to try in order.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the first successful result.

template<typename **Pred**, typename **Action**, typename ...**Ts**>

hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*Action*, *hpx*::id_type, *Ts*...>> **hpx_invoke**(*async_replay_validate_t*, *std*::vector<*hpx*::id_type> const &ids, *Pred* &&pred, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replay_validate CPO.

Asynchronously launches *action* on localities in *ids*, validating results with *pred*. Replays on the next locality on error (aborts on abort_replay_exception).

Parameters

- **tag** – CPO tag (async_replay_validate_t).
- **ids** – Target localities to try in order.
- **pred** – Predicate validating each invocation result.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the first valid result.

hpx/resiliency_distributed/async_replicate_distributed.hpp

Defined in header hpx/resiliency_distributed/async_replicate_distributed.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resiliency**

namespace **experimental**

Functions

template<typename **Vote**, typename **Pred**, typename **Action**, typename ...**Ts**>

decltype(auto) **hpx_invoke**(*async_replicate_vote_validate_t*, *std*::vector<*hpx*::id_type> const &ids, *Vote* &&vote, *Pred* &&pred, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate_vote_validate CPO.

Asynchronously launches *action* on each locality in *ids*, validates results with *pred*, then runs valid results through *vote*.

Parameters

- **tag** – CPO tag (async_replicate_vote_validate_t).
- **ids** – Target localities (one invocation per locality).
- **vote** – Voting function selecting among valid results.
- **pred** – Predicate validating each invocation result.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the voted-upon result.

template<typename **Vote**, typename **Action**, typename ...**Ts**>

decltype(auto) **hpx_invoke**(*async_replicate_vote_t*, *std*::vector<*hpx*::id_type> const &ids, *Vote* &&vote, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate_vote CPO.

Asynchronously launches *action* on each locality in *ids*, runs valid results through *vote*. Validation uses the default exception check.

Parameters

- **tag** – CPO tag (async_replicate_vote_t).
- **ids** – Target localities (one invocation per locality).
- **vote** – Voting function selecting among valid results.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the voted-upon result.

template<typename **Pred**, typename **Action**, typename ...**Ts**>

decltype(auto) **hpx_invoke**(*async_replicate_validate_t*, *std*::vector<*hpx*::id_type> const &ids, *Pred* &&pred, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate_validate CPO.

Asynchronously launches *action* on each locality in *ids*, validates results with *pred*. Returns the first valid result.

Parameters

- **tag** – CPO tag (async_replicate_validate_t).
- **ids** – Target localities (one invocation per locality).
- **pred** – Predicate validating each invocation result.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the first valid result.

template<typename **Action**, typename ...**Ts**>

decltype(auto) **hpx_invoke**(*async_replicate_t*, *std*::vector<*hpx*::id_type> const &ids, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate CPO.

Asynchronously launches *action* on each locality in *ids*. Validates by checking for exceptions. Returns the first valid result.

Parameters

- **tag** – CPO tag (async_replicate_t).
- **ids** – Target localities (one invocation per locality).
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the first non-throwing result.

runtime_components

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/runtime_components/macros.hpp

Defined in header hpx/runtime_components/macros.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

`HPX_REGISTER_MINIMAL_COMPONENT_FACTORY`(...)

namespace **hpx**

Functions

components::*server*::*runtime_support* *`get_runtime_support_ptr`()

namespace **components**

namespace **server**

namespace **stubs**

namespace **components**

hpx::new_

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Component**, typename ...**Ts**>

auto *hpx*::**new_**(id_type const &locality, *Ts*&&... vs)

Create one or more new instances of the given Component type on the specified locality.

This function creates one or more new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

> **Note**
>
> This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:
>
> ```
> hpx::future<hpx::id_type> f =
>    hpx::new_<some_component>(hpx::find_here(), ...);
> hpx::id_type id = f.get();
> ```

Parameters

- **locality** – [in] The global address of the locality where the new instance should be created on.
- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

template<typename **Component**, typename ...**Ts**>

auto *hpx*::**new_**(id_type const &locality, *std*::size_t count, *Ts*&&... vs)

Create multiple new instances of the given Component type on the specified locality.

This function creates multiple new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type> > f =
   hpx::new_<some_component[]>(hpx::find_here(), 10, ...);
hpx::id_type id = f.get();
```

Parameters

- **`locality`** – [in] The global address of the locality where the new instance should be created on.
- **`count`** – [in] The number of component instances to create
- **`vs`** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. *Component*[], where `traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument *Component* represents an array of a client side object type (i.e. *Component*[], where `traits::is_client<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

template<typename **Component**, typename **DistPolicy**, typename ...**Ts**>

auto *hpx*::**new_**(*DistPolicy* const &policy, *Ts*&&... vs)

Create one or more new instances of the given Component type based on the given distribution policy.

This function creates one or more new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for global address which can be used to reference the new component instance(s).

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
   hpx::new_<some_component>(hpx::default_layout, ...);
hpx::id_type id = f.get();
```

Parameters

- **policy** – [in] The distribution policy used to decide where to place the newly created.
- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

template<typename **Component**, typename **DistPolicy**, typename ...**Ts**>

auto *hpx*::**new_**(*DistPolicy* const &policy, *std*::size_t count, *Ts*&&... vs)

Create multiple new instances of the given Component type on the localities as defined by the given distribution policy.

This function creates multiple new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for the global address which can be used to reference the new component instance.

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type> > f =
   hpx::new_<some_component[]>(hpx::default_layout, 10, ...);
hpx::id_type id = f.get();
```

Parameters

- **policy** – [in] The distribution policy used to decide where to place the newly created.

- **count** – [in] The number of component instances to create
- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. *Component*[], where `traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument *Component* represents an array of a client side object type (i.e. *Component*[], where `traits::is_client<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

hpx/runtime_components/component_registry.hpp

Defined in header hpx/runtime_components/component_registry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

template<typename **Component**, *factory_state* **state**>

struct **component_registry** : public *component_registry_base*

#include <component_registry.hpp> The component_registry provides a minimal implementation of a component's registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a component's registry instance.

Template Parameters

Component – The component type this registry should be responsible for.

Public Functions

inline bool **get_component_info**(*std*::vector<*std*::string> &fillini, *std*::string const &filepath, bool is_static = false) override

Return the ini-information for all contained components.

Parameters

- **fillini** – [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.
- **filepath** –
- **is_static** –

Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

inline void **register_component_type**() override

Enables this type of registry and sets its destroy mechanism.

runtime_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/runtime_distributed.hpp

Defined in header hpx/runtime_distributed.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

class **runtime_distributed** : public *runtime*

#include <runtime_distributed.hpp> The *runtime* class encapsulates the HPX runtime system in a simple to use way. It makes sure all required parts of the HPX runtime system are properly initialized.

Public Functions

explicit **runtime_distributed**(*util*::*runtime_configuration* &rtcfg, int (*pre_main)(*runtime_mode*) = nullptr, void (*post_main)() = nullptr)

Construct a new HPX runtime instance

Parameters

- **rtcfg** – Runtime configuration for this instance
- **pre_main** – Function to be called before running the main action of this instance
- **post_main** – Function to be called after running the main action of this instance

~runtime_distributed()

The destructor makes sure all HPX runtime services are properly shut down before exiting.

int **start**(*hpx*::*function*<hpx_main_function_type> const &func, bool blocking = false) override

Start the runtime system.

Parameters

- **func** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*.
- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally.

Returns

If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

int **start**(bool blocking = false) override

Start the runtime system.

Parameters

blocking – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally .

Returns

If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

int **wait**() override

Wait for the shutdown action to be executed.

Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

void **stop**(bool blocking = true) override

Initiate termination of the runtime system.

Parameters

blocking – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

int **finalize**(double shutdown_timeout) override

void **stop_helper**(bool blocking, *std*::condition_variable &cond, *std*::mutex &mtx)

Stop the runtime system, wait for termination.

Parameters

- `blocking` – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.
- `cond` – Condition used to update all thread when done
- `mtx` – Mutex used by this function to sync all threads

int **suspend**() override

Suspend the runtime system.

int **resume**() override

Resume the runtime system.

bool **report_error**(*std*::size_t num_thread, *std*::exception_ptr const &e, bool terminate_all = true) override

Report a non-recoverable error to the runtime system.

Parameters

- `num_thread` – [in] The number of the operating system thread the error has been detected in.
- `e` – [in] This is an instance encapsulating an exception which lead to this function call.
- `terminate_all` – [in] Kill all localities attached to the currently running application (default: true)

bool **report_error**(*std*::exception_ptr const &e, bool terminate_all = true) override

Report a non-recoverable error to the runtime system.

> **Note**
>
> This function will retrieve the number of the current shepherd thread and forward to the report_error function above.

Parameters

- `e` – [in] This is an instance encapsulating an exception which lead to this function call.
- `terminate_all` – [in] Kill all localities attached to the currently running application (default: true)

int **run**(*hpx*::*function*<hpx_main_function_type> const &func) override

Run the HPX runtime system, use the given function for the main *thread* and block waiting for all threads to finish.

> **Note**
>
> The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

Parameters

`func` – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

int **run**() override

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

Returns

This function will always return 0 (zero).

bool **is_networking_enabled**() override

template<typename **F**>

inline *components*::*server*::console_error_dispatcher::sink_type **set_error_sink**(*F* &&sink)

performance_counters::registry &**get_counter_registry**()

Allow access to the registry counter registry instance used by the HPX runtime.

performance_counters::registry const &**get_counter_registry**() const

Allow access to the registry counter registry instance used by the HPX runtime.

void **register_query_counters**(*std*::shared_ptr<*util*::query_counters> const &active_counters)

void **start_active_counters**(*error_code* &ec = *throws*) const

void **stop_active_counters**(*error_code* &ec = *throws*) const

void **reset_active_counters**(*error_code* &ec = *throws*) const

void **reinit_active_counters**(bool reset = true, *error_code* &ec = *throws*) const

void **evaluate_active_counters**(bool reset = false, char const *description = nullptr, *error_code* &ec = *throws*) const void **stop_evaluating_counters**(bool terminate = false) const

agas::*addressing_service* &**get_agas_client**()

Allow access to the AGAS client instance used by the HPX runtime.

hpx::*threads*::*threadmanager* &**get_thread_manager**() override

Allow access to the thread manager instance used by the HPX runtime.

applier::*applier* &**get_applier**()

Allow access to the applier instance used by the HPX runtime.

std::string **here**() const override

Returns a string of the locality endpoints (usable in debug output)

naming::address_type **get_runtime_support_lva**() const

naming::gid_type **get_next_id**(*std*::size_t count = 1)

void **init_id_pool_range**()

util::unique_id_ranges &**get_id_pool**()

void **initialize_agas**()

Initialize AGAS operation.

void **add_pre_startup_function**(*startup_function_type* f) override

Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with *add_startup_function*.

> **Note**
>
> The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

Parameters

f – The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void **add_startup_function**(*startup_function_type* f) override

Add a function to be executed inside a HPX thread before hpx_main

Parameters

f – The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void **add_pre_shutdown_function**(*shutdown_function_type* f) override

Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

> **Note**
>
> The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

Parameters

f – The function 'f' will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

void **add_shutdown_function**(*shutdown_function_type* f) override

Add a function to be executed inside a HPX thread during hpx::finalize

Parameters

f – The function 'f' will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

hpx::*util*::*io_service_pool* ***get_thread_pool**(char const *name) override

Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks. The three possible values for the argument `name` are "main_pool", "io_pool", "parcel_pool", and "timer_pool". For any other argument value the function will return zero.

bool **register_thread**(char const *name, *std*::size_t num = 0, bool service_thread = true, *error_code* &ec = *throws*) override

Register an external OS-thread with HPX.

notification_policy_type **get_notification_policy**(char const *prefix, runtime_local::os_thread_type type) override

Generate a new notification policy instance for the given thread name prefix

std::uint32_t **get_locality_id**(*error_code* &ec) const override

std::size_t **get_num_worker_threads**() const override *std*::uint32_t **get_num_localities**(*hpx*::*launch*::sync_policy, *error_code* &ec) const override

std::uint32_t **get_initial_num_localities**() const override

hpx::*future*<*std*::uint32_t> **get_num_localities**() const override

std::string **get_locality_name**() const override

std::uint32_t **get_num_localities**(*hpx*::*launch*::sync_policy, *components*::component_type type, *error_code* &ec) const

hpx::find_locality

Defined in header hpx/runtime.hpp[594].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::id_type *hpx*::**find_locality**(*components*::component_type type, *error_code* &ec = *throws*)

Return the global id representing an arbitrary locality which supports the given component type.

The function find_locality() can be used to retrieve the global id of an arbitrary locality currently available to this application which supports the creation of instances of the given component type.

See also

hpx::find_here(), hpx::find_all_localities()

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

[594] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/runtime.hpp

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

Parameters

- **type** – [in] The type of the components for which the function should return any available locality.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id representing an arbitrary locality currently available to this application which supports the creation of instances of the given component type. If no locality supporting the given component type is currently available, this function will return *hpx::invalid_id*.

hpx/runtime_distributed/applier.hpp

Defined in header hpx/runtime_distributed/applier.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **applier**

class **applier**

#include <applier.hpp> The *applier* class is used to decide whether a particular action has to be issued on a local or a remote resource. If the target component is local a new *thread* will be created, if the target is remote a parcel will be sent.

Public Functions

applier(*applier* const&) = delete

applier(*applier*&&) = delete

applier &**operator=**(*applier* const&) = delete

applier &**operator=**(*applier*&&) = delete

applier()

void **init**(*threads*::*threadmanager* &tm)

~applier() = default

void **initialize**(*std*::uint64_t rts)

threads::*threadmanager* &**get_thread_manager**()

Access the *thread-manager* instance associated with this *applier*.

This function returns a reference to the thread manager this applier instance has been created with.

naming::gid_type const &**get_raw_locality**(*error_code* &ec = *throws*) const

Allow access to the locality of the locality this applier instance is associated with.

This function returns a reference to the locality this applier instance is associated with.

std::uint32_t **get_locality_id**(*error_code* &ec = *throws*) const

Allow access to the id of the locality this applier instance is associated with.

This function returns a reference to the id of the locality this applier instance is associated with.

bool **get_raw_remote_localities**(*std*::vector<*naming*::gid_type> &locality_ids, *components*::component_type type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*), *error_code* &ec = *throws*) const

Return list of localities of all remote localities registered with the AGAS service for a specific component type.

This function returns a list of all remote localities (all localities known to AGAS except the local one) supporting the given component type.

Parameters

- `locality_ids` – [out] The reference to a vector of id_types filled by the function.
- `type` – [in] The type of the component which needs to exist on the returned localities.

Returns

The function returns *true* if there is at least one remote locality known to the AGAS service (!prefixes.empty()).

bool `get_remote_localities`(*std*::vector<*hpx*::id_type> &locality_ids, *components*::component_type type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*), *error_code* &ec = *throws*) const

bool `get_raw_localities`(*std*::vector<*naming*::gid_type> &locality_ids, *components*::component_type type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*)) const

Return list of locality_ids of all localities registered with the AGAS service for a specific component type.

This function returns a list of all localities (all localities known to AGAS except the local one) supporting the given component type.

Parameters

- `locality_ids` – [out] The reference to a vector of id_types filled by the function.
- `type` – [in] The type of the component which needs to exist on the returned localities.

Returns

The function returns *true* if there is at least one remote locality known to the AGAS service (!prefixes.empty()).

bool `get_localities`(*std*::vector<*hpx*::id_type> &locality_ids, *error_code* &ec = *throws*) const

bool `get_localities`(*std*::vector<*hpx*::id_type> &locality_ids, *components*::component_type type, *error_code* &ec = *throws*) const

inline *naming*::gid_type const &`get_runtime_support_raw_gid`() const

By convention the runtime_support has a gid identical to the prefix of the locality the runtime_support is responsible for

hpx/runtime_distributed/get_num_localities.hpp

Defined in header hpx/runtime_distributed/get_num_localities.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

hpx::*future*<*std*::uint32_t> **get_num_localities**(*components*::component_type t)

Asynchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* asynchronously returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

> **See also**
>
> *hpx::find_all_localities*, *hpx::get_num_localities*

> **Note**
>
> This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Parameters

t – The component type for which the number of connected localities should be retrieved.

std::uint32_t **get_num_localities**(*launch*::sync_policy, *components*::component_type t, *error_code* &ec = *throws*)

Synchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

> **See also**
>
> *hpx::find_all_localities*, *hpx::get_num_localities*

> **Note**
>
> This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Parameters

- `t` – The component type for which the number of connected localities should be retrieved.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx/runtime_distributed/get_locality_name.hpp

Defined in header hpx/runtime_distributed/get_locality_name.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

future<*std*::string> **get_locality_name**(*hpx*::id_type const &id)

Return the name of the referenced locality.

This function returns a future referring to the name for the locality of the given id.

> **See also**
>
> *std::string get_locality_name()*

Parameters

`id` – [in] The global id of the locality for which the name should be retrieved

Returns

This function returns the name for the locality of the given id. The name is retrieved from the underlying networking layer and may be different for different parcel ports.

hpx::find_root_locality

Defined in header hpx/runtime.hpp[595].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_all_localities*
- *hpx::find_remote_localities*

hpx::id_type **hpx::find_root_locality**(*error_code* &ec = *throws*)

Return the global id representing the root locality.

The function find_root_locality() can be used to retrieve the global id usable to refer to the root locality. The root locality is the locality where the main AGAS service is hosted.

> **See also**
>
> hpx::find_all_localities(), hpx::find_locality()

> **Note**
>
> Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

> **Note**
>
> This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id representing the root locality for this application.

[595] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/runtime.hpp

hpx::find_all_localities

Defined in header hpx/runtime.hpp[596].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_root_locality*
- *hpx::find_remote_localities*

std::vector<*hpx*::id_type> **hpx::find_all_localities**(*error_code* &ec = *throws*)

Return the list of global ids representing all localities available to this application.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application.

> **See also**
>
> *hpx::find_here()*, hpx::find_locality()

> **Note**
>
> Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

> **Note**
>
> This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the localities currently available to this application.

std::vector<*hpx*::id_type> **hpx::find_all_localities**(*components*::component_type type, *error_code* &ec = *throws*)

[596] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/runtime.hpp

Return the list of global ids representing all localities available to this application which support the given component type.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application which support the creation of instances of the given component type.

> **See also**
>
> *hpx::find_here()*, hpx::find_locality()

> **Note**
>
> Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

> **Note**
>
> This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

- **`type`** – [in] The type of the components for which the function should return the available localities.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the localities currently available to this application which support the creation of instances of the given component type. If no localities supporting the given component type are currently available, this function will return an empty vector.

hpx::find_remote_localities

Defined in header hpx/runtime.hpp[597].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_root_locality*
- *hpx::find_all_localities*

std::vector<*hpx*::id_type> **hpx::find_remote_localities**(*error_code* &ec = *throws*)

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one).

See also

hpx::find_here(), hpx::find_locality()

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

ec – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the remote localities currently available to this application.

[597] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/runtime.hpp

std::vector<*hpx*::id_type> `hpx::find_remote_localities`(*components*::component_type type, *error_code* &ec = *throws*)

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one) which support the creation of instances of the given component type.

See also

hpx::find_here(), hpx::find_locality()

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

- **type** – [in] The type of the components for which the function should return the available remote localities.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the remote localities currently available to this application.

hpx/runtime_distributed/big_boot_barrier.hpp

Defined in header hpx/runtime_distributed/big_boot_barrier.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/runtime_distributed/migrate_component.hpp

Defined in header hpx/runtime_distributed/migrate_component.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Functions

template<typename **Component**, typename **DistPolicy**>

future<*hpx*::id_type> **migrate**(*hpx*::id_type const &to_migrate, [[maybe_unused]] *DistPolicy* const &policy)

Migrate the given component to the specified target locality

The function *migrate<Component>* will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The client side representation of the component to migrate.
- **policy** – [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- **Component** – Specifies the component type of the component to migrate.
- **DistPolicy** – Specifies the distribution policy to use to determine the destination locality.

Returns

A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

template<typename **Derived**, typename **Stub**, typename **Data**, typename **DistPolicy**>

Derived **migrate**(*client_base*<*Derived*, *Stub*, *Data*> const &to_migrate, *DistPolicy* const &policy)

Migrate the given component to the specified target locality

The function *migrate<Component>* will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The client side representation of the component to migrate.
- **policy** – [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- **Derived** – Specifies the component type of the component to migrate.
- **DistPolicy** – Specifies the distribution policy to use to determine the destination locality.

Returns

A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

template<typename **Component**>

future<*hpx*::id_type> **migrate**(*hpx*::id_type const &to_migrate, *hpx*::id_type const &target_locality)

Migrate the component with the given id to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The global id of the component to migrate.
- **target_locality** – [in] The locality where the component should be migrated to.

Template Parameters

Component – Specifies the component type of the component to migrate.

Returns

A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

template<typename **Derived**, typename **Stub**, typename **Data**>

Derived **migrate**(*client_base*<*Derived*, *Stub*, *Data*> const &to_migrate, *hpx*::id_type const &target_locality)

Migrate the given component to the specified target locality

The function *migrate*<*Component*> will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The client side representation of the component to migrate.
- **target_locality** – [in] The id of the locality to migrate this object to.

Template Parameters

Derived – Specifies the component type of the component to migrate.

Returns

A client side representation of representing of the migrated component instance. This should be the same as *migrate_to*.

hpx/runtime_distributed/copy_component.hpp

Defined in header hpx/runtime_distributed/copy_component.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Functions

template<typename **Component**>

future<*hpx*::id_type> **copy**(*hpx*::id_type const &to_copy)

Copy given component to the specified target locality.

The function *copy*<*Component*> will create a copy of the component referenced by *to_copy* on the locality specified with *target_locality*. It returns a future referring to the newly created component instance.

> **Note**
>
> The new component instance is created on the locality of the component instance which is to be copied.

Parameters
to_copy – [in] The global id of the component to copy

Template Parameters
The – only template argument specifies the component type to create.

Returns
A future representing the global id of the newly (copied) component instance.

template<typename **Component**>

future<*hpx*::id_type> **copy**(*hpx*::id_type const &to_copy, *hpx*::id_type const &target_locality)

Copy given component to the specified target locality.

The function *copy*<*Component*> will create a copy of the component referenced by *to_copy* on the locality specified with *target_locality*. It returns a future referring to the newly created component instance.

Parameters

- **to_copy** – [in] The global id of the component to copy
- **target_locality** – [in] The locality where the copy should be created.

Template Parameters
The – only template argument specifies the component type to create.

Returns
A future representing the global id of the newly (copied) component instance.

template<typename **Derived**, typename **Stub**, typename **Data**>

Derived **copy**(*client_base*<*Derived*, *Stub*, *Data*> const &to_copy, *hpx*::id_type const &target_locality = *hpx*::invalid_id)

Copy given component to the specified target locality.

The function *copy* will create a copy of the component referenced by the client side object *to_copy* on the locality specified with *target_locality*. It returns a new client side object future referring to the newly created component instance.

Note

If the second argument is omitted (or is invalid_id) the new component instance is created on the locality of the component instance which is to be copied.

Parameters

- **to_copy** – [in] The client side object representing the component to copy
- **target_locality** – [in, optional] The locality where the copy should be created (default is same locality as source).

Template Parameters

The – only template argument specifies the component type to create.

Returns

A future representing the global id of the newly (copied) component instance.

hpx/runtime_distributed/runtime_support.hpp

Defined in header hpx/runtime_distributed/runtime_support.hpp.

hpx/runtime_distributed/find_here.hpp

Defined in header hpx/runtime_distributed/find_here.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

hpx::id_type **find_here**(*error_code* &ec = *throws*)

Return the global id representing this locality.

The function find_here() can be used to retrieve the global id usable to refer to the current locality.

See also

hpx::find_all_localities(), *hpx::find_locality()*

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Note

This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

Parameters
`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns
The global id representing the locality this function has been called on.

hpx/runtime_distributed/runtime_fwd.hpp

Defined in header hpx/runtime_distributed/runtime_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

runtime_distributed &**get_runtime_distributed**()

runtime_distributed *&**get_runtime_distributed_ptr**()

naming::gid_type const &**get_locality**()

The function *get_locality* returns a reference to the locality prefix.

void **start_active_counters**(*error_code* &ec = *throws*)

Start all active performance counters, optionally naming the section of code.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters
`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **reset_active_counters**(*error_code* &ec = *throws*)

Resets all active performance counters.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **reinit_active_counters**(bool reset = true, *error_code* &ec = *throws*)

Re-initialize all active performance counters.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

- `reset` – [in] Reset the current values before re-initializing counters (default: true)
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **stop_active_counters**(*error_code* &ec = *throws*)

Stop all active performance counters.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

ec – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **evaluate_active_counters**(bool reset = false, char const *description = nullptr, *error_code* &ec = *throws*)

Evaluate and output all active performance counters, optionally naming the point in code marked by this function.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> The output generated by this function is redirected to the destination specified by the corresponding command line options (see –hpx:print-counter-destination).

> **Note**
>
> The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

- **reset** – [in] this is an optional flag allowing to reset the counter value after it has been evaluated.
- **description** – [in] this is an optional value naming the point in the code marked by the call to this function.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

serialization::binary_filter ***create_binary_filter**(char const *binary_filter_type, bool compress, *serialization*::binary_filter *next_filter = nullptr, *error_code* &ec = *throws*)

Create an instance of a binary filter plugin.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **binary_filter_type** – [in] The type of the binary filter to create
- **compress** – [in] The created filter should support compression
- **next_filter** – [in] Use this as the filter to dispatch the invocation into.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx/runtime_distributed/applier_fwd.hpp

Defined in header hpx/runtime_distributed/applier_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **applier**

Functions

applier &**get_applier**()

The function *get_applier* returns a reference to the (thread specific) applier instance.

applier ***get_applier_ptr**()

The function *get_applier* returns a pointer to the (thread specific) applier instance. The returned pointer is NULL if the current thread is not known to HPX or if the runtime system is not active.

namespace **applier**

The namespace *applier* contains all definitions needed for the class hpx::applier::applier and its related functionality. This namespace is part of the HPX core module.

hpx/runtime_distributed/server/copy_component.hpp

Defined in header hpx/runtime_distributed/server/copy_component.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

void **shutdown**(double timeout, *hpx*::id_type const &respond_to, bool force_disconnect)

Gracefully shutdown this runtime system instance.

void **shutdown_all**(double timeout)

Gracefully shutdown runtime system instances on all localities.

void **terminate**(*hpx*::id_type const &respond_to)

Shutdown this runtime system instance.

inline void **terminate_act**(*hpx*::id_type const &id)

void **terminate_all**()

Shutdown runtime system instances on all localities.

inline void **terminate_all_act**()

util::section **get_config**()

Retrieve configuration information.

int **load_components**()

Load all components on this locality.

void **call_startup_functions**(bool pre_startup)

void **call_shutdown_functions**(bool pre_shutdown)

void **garbage_collect**()

Force a garbage collection operation in the AGAS layer.

naming::gid_type **create_performance_counter**(performance_counters::counter_info const &info)

Create the given performance counter instance.

void **remove_from_connection_cache**(*naming*::gid_type const &gid, *parcelset*::endpoints_type const &eps)

Remove the given locality from our connection cache.

HPX_DEFINE_COMPONENT_ACTION (runtime_support, terminate_act, terminate_action) HPX_DEFINE_COMPONENT_ACTION(runtime_support

termination detection

terminate_all_action HPX_DEFINE_COMPONENT_ACTION (runtime_support, remove_from_connection_cache) void run()

Start the *runtime_support* component.

void **wait**()

Wait for the *runtime_support* component to notify the calling thread.

This function will be called from the main thread, causing it to block while the HPX functionality is executed. The main thread will block until the shutdown_action is executed, which in turn notifies all waiting threads.

void **stop**(double timeout, *hpx*::id_type const &respond_to, bool remove_from_remote_caches, bool force_disconnect)

Notify all waiting (blocking) threads allowing the system to be properly stopped.

> **Note**
>
> This function can be called from any thread.

bool **remove_locality**(*hpx*::id_type const &locality, *error_code* &ec = *hpx*::*throws*)

Remove the given locality from this locality's runtime support component.

> **Note**
>
> This function must be called locally only; it is not exposed as a component action.

Parameters

- `locality` – The locality to be removed.
- `ec` – Used to hold error code value originating from the AGAS operations invoked by this function.

void **stopped**()

void **notify_waiting_main**()

inline bool **was_stopped**() const

Public Static Functions

static inline component_type **get_component_type**()

static inline void **set_component_type**(component_type t) static inline constexpr void **finalize**()

finalize() will be called just before the instance gets destructed

static inline bool **is_target_valid**(*hpx*::id_type const &id)

static void **remove_locality_from_connection_cache**(*hpx*::*naming*::gid_type const &locality, bool skip_current = false)

Broadcast a request to remove the given locality from the connection caches of all remote, non-console localities.

Parameters

- **locality** – The locality to remove from the remote connection caches.
- **skip_current** – If true, omits the locality identified by *locality* from this broadcast (that locality will not receive a removal request for itself).

static void **remove_locality_from_console_connection_cache**(*hpx*::*naming*::gid_type const &locality)

Remove the given locality from the console's connection cache.

Parameters

locality – The locality to remove from the console's connection cache.

Protected Functions

supervision

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::supervision::publish_event

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*

hpx::*future*<publish_result> `hpx::supervision::`**`publish_event`**(*hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0)

Publish a lifecycle event for a target actor on a possibly remote locality.

The function publish_event() asynchronously notifies the supervision manager running on *locality* that *target* has reached the lifecycle state *ev*. Registered observers of *target* are notified as a result.

> **Note**
>
> Publishing is not idempotent: publishing the same event twice creates two distinct records with different timestamps.

> **Note**
>
> Events are immediately visible to observers on the same locality as *target*; remote observers become aware of the event within about 1-2 parcel round-trips to the AGAS authority managing the actor's registration.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) for which the event is published.
- **`ev`** – [in] The lifecycle event to publish for *target*.
- **`epoch`** – [in] The epoch this publication belongs to. Publications are compared against the target's current epoch: publications for a lower epoch are rejected as stale no-ops, publications for a higher epoch reset the target's sequence number and become the new current epoch, and publications for the current epoch are applied normally (subject to terminal-state latching).

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once the event has been recorded by the supervision manager on *locality*, holding `publish_result::applied`, `publish_result::already_terminal` if *target* had already reached a terminal event (`completed` or `failed`) within *epoch*, or `publish_result::stale_epoch` if *epoch* is lower than the target's current epoch.

publish_result *`hpx::supervision::`***`publish_event`**(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *hpx*::*throws*)

Publish a lifecycle event for a target actor on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of *publish_event(hpx::id_type const&, hpx::id_type const&, event)*.

Note

Publishing non-terminal events is not idempotent: publishing the same event twice creates two distinct records with different timestamps. `event::completed` and `event::failed` are latched: the first terminal publication for a target wins, and every later terminal publication for that target is a no-op that returns `publish_result::already_terminal`.

Parameters

- **locality** – [in] The locality on which the supervision manager responsible for *target* is running.
- **target** – [in] The actor (or component) for which the event is published.
- **ev** – [in] The lifecycle event to publish for *target*.
- **epoch** – [in] The epoch this publication belongs to. See the asynchronous remote overload for the epoch-scoped semantics.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*. As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*.

Returns

`publish_result::applied`, `publish_result::already_terminal` if *target* had already reached a terminal event (`completed` or `failed`) within *epoch*, or `publish_result::stale_epoch` if *epoch* is lower than the target's current epoch.

publish_result `hpx::supervision::`**`publish_event`**(*hpx*::id_type const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *throws*)

Publish a lifecycle event for a target actor on the local locality.

This overload publishes *ev* directly through the local supervision manager without going through AGAS or a remote parcel. It is intended to be called from within an actor or action running on the same locality as *target*.

Note

Publishing non-terminal events is not idempotent: publishing the same event twice creates two distinct records with different timestamps. `event::completed` and `event::failed` are latched: the first terminal publication for a target wins, and every later terminal publication for that target is a no-op that returns `publish_result::already_terminal`.

Note

Local observers of *target* are notified synchronously as part of this call.

Parameters

- `target` – [in] The actor (or component) for which the event is published. Must be local to the calling locality.
- `ev` – [in] The lifecycle event to publish for *target*.
- `epoch` – [in] The epoch this publication belongs to. See the asynchronous remote overload for the epoch-scoped semantics.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

hpx::exception – if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

`publish_result::applied`, `publish_result::already_terminal` if *target* had already reached a terminal event (`completed` or `failed`) within *epoch*, or `publish_result::stale_epoch` if *epoch* is lower than the target's current epoch.

hpx::*future*<publish_result> *hpx*::*supervision*::**publish_event**(*registry* const &handle, event ev, *std*::uint64_t epoch = 0)

Publish a lifecycle event for the local locality tracked by *handle*.

Convenience overload of hpx::supervision::publish_event(hpx::id_type const&, hpx::id_type const&, event, std::uint64_t) that resolves both locality and target to *hpx::find_here()* instead of requiring the caller to name them explicitly. Forwards to *hpx::supervision::publish_event*(`hpx::find_here(), hpx::find_here(), ev, epoch`).

Parameters

- `handle` – [in] The registry (typically returned by *init()*) whose locality the event is published for.
- `ev` – [in] The lifecycle event to publish.
- `epoch` – [in] The epoch this publication belongs to. Typically obtained from a prior `query_state(hpx::launch::sync, handle).epoch` call. See the raw-id overload for the epoch-scoped semantics.

Returns

A future that becomes ready once the event has been recorded, holding the same *publish_result* values as the raw-id overload.

publish_result *hpx*::*supervision*::**publish_event**(*hpx*::*launch*::sync_policy policy, *registry* const &handle, event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *hpx*::*throws*)

Publish a lifecycle event for the local locality tracked by *handle*, blocking until the operation has completed.

This is the synchronous equivalent of publish_event(registry const&, event, std::uint64_t).

Parameters

- **policy** – [in] Tag selecting the blocking overload of *publish_event()*.
- **handle** – [in] The registry whose locality the event is published for.
- **ev** – [in] The lifecycle event to publish.
- **epoch** – [in] The epoch this publication belongs to. See the asynchronous overload.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws
`hpx::exception` – if *handle* does not hold a valid registry client, unless *ec* was pre-initialized to something other than *hpx::throws*.

Returns
The same *publish_result* values as the raw-id overload.

hpx::supervision::query_state

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<lifecycle_state> `hpx::supervision::`**`query_state`**(*hpx*::id_type const &locality, *hpx*::id_type const &target)

Query the last known lifecycle state of a target actor on a possibly remote locality.

The function query_state() asynchronously retrieves the most recently published lifecycle event for *target*, as observed by the supervision manager running on *locality*.

> **Note**
>
> If *target* is not local to *locality*, the query is forwarded to the actor's home locality, adding about one parcel round-trip of latency.

> **Note**
>
> The returned *lifecycle_state::ec* may carry a staleness error code, indicating that the returned state may be stale if a preceding observer parcel has not yet been delivered.

> **Note**
>
> The *lifecycle_state::event_sequence_number* allows clients to detect gaps, e.g. if an observer callback was skipped due to a network failure.

Parameters

- **locality** – [in] The locality on which the supervision manager responsible for *target* is running.
- **target** – [in] The actor (or component) whose state is queried.

Throws

hpx::exception – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future holding the last event recorded for *target* (i.e., the most recent value in the runtime's event log), together with its timestamp and sequence number.

lifecycle_state *hpx::supervision::***query_state**(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the last known lifecycle state of a target actor on a possibly remote locality, blocking until the result is available.

This is the synchronous equivalent of query_state(hpx::id_type const&, hpx::id_type const&).

> **Note**
>
> The returned *lifecycle_state::ec* may carry a staleness error code, indicating that the returned state may be stale if a preceding observer parcel has not yet been delivered.

Parameters

- **locality** – [in] The locality on which the supervision manager responsible for *target* is running.
- **target** – [in] The actor (or component) whose state is queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

The last event recorded for *target*, together with its timestamp and sequence number.

lifecycle_state `hpx::supervision::query_state`(*hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the last known lifecycle state of a target actor on the local locality.

Parameters

- `target` – [in] The actor (or component) whose state is queried. Must be local to the calling locality.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

The last event recorded locally for *target*, together with its timestamp and sequence number.

hpx::*future*<lifecycle_state> `hpx::supervision::query_state`(*registry* const &handle)

Query the last known lifecycle state of the local locality, as tracked by *handle*.

Convenience overload of hpx::supervision::query_state(hpx::id_type const&, hpx::id_type const&) that resolves both the locality and the target to *hpx::find_here()* instead of requiring the caller to name them explicitly. Forwards to `hpx::supervision::query_state(hpx::find_here(), hpx::find_here())`.

Parameters

`handle` – [in] The registry (typically returned by *init()*) whose locality's state is queried.

Returns

A future holding the last event recorded for the local locality, together with its timestamp, sequence number, and epoch (see *lifecycle_state::epoch* — in particular, useful for recovering the epoch init() started this locality's lifecycle tracking at, for use with *publish_event()*).

lifecycle_state `hpx::supervision::query_state`(*hpx*::*launch*::sync_policy policy, *registry* const &handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the last known lifecycle state of the local locality, as tracked by *handle*, blocking until the result is available.

This is the synchronous equivalent of query_state(registry const&).

Parameters

- `policy` – Tag selecting the blocking overload of *query_state()*.
- `handle` – [in] The registry whose locality's state is queried.

- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws
hpx::exception – if *handle* does not hold a valid registry client, unless *ec* was pre-initialized to something other than *hpx::throws*.

Returns
The last event recorded for the local locality.

hpx::*future*<lifecycle_state> *hpx::supervision*::**query_state**(*registry* const &handle, *discovered_peer* const &peer)

Query the last known lifecycle state of a discovered peer's locality.

Convenience overload of hpx::supervision::query_state(hpx::id_type const&, hpx::id_type const&) that resolves both the locality and the target to *peer.locality* instead of requiring the caller to name them explicitly — mirroring the self-query overload above, but issued against *peer.locality's* own supervision manager instead of the local one. Forwards to `hpx::supervision::query_state(peer.locality, peer.locality)`.

Parameters

- **handle** – [in] Unused beyond overload resolution and symmetry with the self-query overload above; *peer* alone carries everything this call needs.
- **peer** – [in] The peer (typically returned by *discover_peers()*/ *discover_and_join()*) whose state is queried.

Returns
A future holding the last event recorded for *peer.locality*, as observed by the supervision manager running on *peer.locality*.

lifecycle_state *hpx::supervision*::**query_state**(*hpx*::*launch*::sync_policy policy, *registry* const &handle, *discovered_peer* const &peer, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the last known lifecycle state of a discovered peer's locality, blocking until the result is available.

This is the synchronous equivalent of query_state(registry const&, discovered_peer const&).

Parameters

- **policy** – Tag selecting the blocking overload of *query_state()*.
- **handle** – [in] Unused beyond overload resolution; see the asynchronous overload.
- **peer** – [in] The peer whose state is queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws
hpx::exception – if *peer.locality* does not hold a valid registry client, unless *ec* was pre-initialized to something other than *hpx::throws*.

Returns
The last event recorded for *peer.locality*.

hpx::supervision::register_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<*hpx*::id_type> `hpx::supervision::register_observer`(*hpx*::id_type const &locality, *hpx*::id_type const &target, lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt)

Register a callback to observe lifecycle events published by a target actor running on a possibly remote locality.

Note

If *locality* is the locality *target* is running on, the callback is invoked synchronously from within the publish call (best effort; the callback must not block indefinitely).

Note

If *locality* differs from the locality *target* is running on, the callback is invoked asynchronously via a dedicated parcel, with retry semantics (e.g., 3 attempts over 500 ms before logging failure).

Note

The callback must not throw; exceptions thrown from it are logged and do not affect the observer registration.

Parameters

- **locality** – [in] The locality on which the callback should be registered.
- **target** – [in] The actor (or component) to observe.

- **callback** – [in] The callback invoked whenever *target* publishes a lifecycle event.
- **epoch_filter** – [in] If set, restricts notifications to events published under this epoch; events published under any other epoch are silently skipped for this observer. If `std::nullopt` (the default), the observer is notified regardless of epoch.

Throws

hpx::exception – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future holding the global id of the observer handle. This handle must be passed to unregister_observer() in order to stop receiving notifications.

hpx::id_type **hpx::supervision::register_observer**(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe lifecycle events published by a target actor running on a possibly remote locality, blocking until the registration has completed.

This is the synchronous equivalent of *register_observer*(hpx::id_type const&, hpx::id_type const&, lifecycle_callback const&).

Parameters

- **locality** – [in] The locality on which the callback should be registered.
- **target** – [in] The actor (or component) to observe.
- **callback** – [in] The callback invoked whenever *target* publishes a lifecycle event.
- **epoch_filter** – [in] If set, restricts notifications to events published under this epoch; see the asynchronous overload for details.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

hpx::exception – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_observer() in order to stop receiving notifications.

hpx::id_type **hpx::supervision::register_observer**(*hpx*::id_type const &target, lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe lifecycle events published by a target actor on the local locality.

> **Note**
>
> The callback is invoked synchronously from within the publish call (best effort; the callback must not block indefinitely) and must not throw; exceptions thrown from it are

logged and do not affect the observer registration.

Parameters

- **target** – [in] The actor (or component) to observe. Must be local to the calling locality.
- **callback** – [in] The callback invoked whenever *target* publishes a lifecycle event.
- **epoch_filter** – [in] If set, restricts notifications to events published under this epoch; events published under any other epoch are silently skipped for this observer. If `std::nullopt` (the default), the observer is notified regardless of epoch.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *target* does not represent a valid target, unless *ec* was initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_observer() in order to stop receiving notifications.

hpx::supervision::unregister_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<void> `hpx::supervision::`**`unregister_observer`**(*hpx*::id_type const &locality, *hpx*::id_type const &observer_handle)

Unregister a previously registered observer on a possibly remote locality.

Note

Once the returned future has become ready, no orphaned callbacks fire after unregistration completes.

Parameters

- **locality** – [in] The locality on which the observer was registered.
- **observer_handle** – [in] The handle returned by a prior call to register_observer(). Only handles returned from that function are accepted; passing a handle obtained from register_activity_observer() (or any foreign handle) is rejected.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid observer handle. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once the observer has been unregistered.

void `hpx::supervision::unregister_observer`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered observer on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of unregister_observer(hpx::id_type const&, hpx::id_type const&).

> **Note**
>
> No orphaned callbacks fire after unregistration completes.

Parameters

- **locality** – [in] The locality on which the observer was registered.
- **observer_handle** – [in] The handle returned by a prior call to register_observer(). See the asynchronous overload regarding foreign handles.
- **ec** – [in,out] this represents the error status on exit, if this pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid observer handle, unless *ec* was initialized not to *hpx::throws*.

void `hpx::supervision::unregister_observer`(*hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered observer on the local locality.

> **Note**
>
> No orphaned callbacks fire after unregistration completes.

Parameters

- **observer_handle** – [in] The handle returned by a prior call to register_observer(). Must be local to the calling locality. See the remote overload regarding foreign handles.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *observer_handle* does not represent a valid observer handle, unless *ec* was not pre-initialized to *hpx::throws*.

hpx::supervision::remove_target

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<void> `hpx::supervision::`**`remove_target`**(*hpx*::id_type const &locality, *hpx*::id_type const &target)

Clear all locally tracked state for a target on a possibly remote locality.

Unlike unregister_observer(), which removes a single previously registered observer handle, remove_target() unconditionally forgets every piece of local state held for *target* - its recorded lifecycle state (see publish_event() / query_state()) and any observers still registered for it (see register_observer()) - regardless of any specific observer handle.

> **Note**
>
> This is intended for callers that know *target* will never be queried or observed again locally (e.g. after a failed registration that seeded some state for it, or once a peer has been evicted), so that local state does not accumulate indefinitely. It is not itself a lifecycle event and does not affect *target's* state on any other locality.

Parameters

- **locality** – [in] The locality on which *target's* state is tracked.
- **target** – [in] The actor (or component) whose locally tracked state should be removed.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once *target's* state has been removed.

void `hpx::supervision::remove_target`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Clear all locally tracked state for a target on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of remove_target(hpx::id_type const&, hpx::id_type const&).

Parameters

- `locality` – [in] The locality on which *target's* state is tracked.
- `target` – [in] The actor (or component) whose locally tracked state should be removed.
- `ec` – [in,out] this represents the error status on exit, if this pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was initialized not to *hpx::throws*.

void `hpx::supervision::remove_target`(*hpx*::id_type const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Clear all locally tracked state for a target on the local locality.

Parameters

- `target` – [in] The actor (or component) whose locally tracked state should be removed. Must be local to the calling locality.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

hpx::supervision::register_activity_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*

- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<*hpx*::id_type> `hpx::supervision::register_activity_observer`(*hpx*::id_type const &locality, activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt)

Register a callback to observe activity-state transitions of all targets tracked on a possibly remote locality.

> **Note**
>
> For every target tracked on *locality* that is already `activity_state::active` at registration time, the new observer synchronously receives one replay notification (carrying `activity_transition::already_active`) as part of registration, taken under the same lock that serializes activity-state transitions. This guarantees the observer sees exactly one notification for each such target's current activity state: either the replay, or a live transition that raced with registration, but never both and never neither.

> **Note**
>
> If *locality* is the local locality, callbacks (including the registration-time replay) are invoked synchronously from within the call that triggered the transition (best effort; the callback must not block indefinitely).

> **Note**
>
> If *locality* is remote, callbacks are invoked asynchronously via a dedicated parcel, with retry semantics (e.g., 3 attempts over 500 ms before logging failure).

> **Note**
>
> The callback must not throw; exceptions thrown from it are logged and do not affect the observer registration.

Parameters

- **`locality`** – [in] The locality on which the callback should be registered.
- **`callback`** – [in] The callback invoked whenever any target tracked on *locality* transitions between *activity_state::inactive* and *activity_state::active*.

- **epoch_filter** – [in] If set, restricts notifications to transitions recorded under this epoch; transitions recorded under any other epoch are silently skipped for this observer. This also applies to the registration-time replay described below. If `std::nullopt` (the default), the observer is notified regardless of epoch.

Throws

hpx::exception – if *locality* does not represent a locality. The returned future becomes exceptional if the operation fails.

Returns

A future holding the global id of the observer handle. This handle must be passed to unregister_activity_observer() in order to stop receiving notifications.

hpx::id_type *hpx*::*supervision*::**register_activity_observer**(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe activity-state transitions of all targets tracked on a possibly remote locality, blocking until the registration has completed.

This is the synchronous equivalent of *register_activity_observer*(hpx::id_type const&, activity_callback const&, std::optional<std::uint64_t>).

Parameters

- **locality** – [in] The locality on which the callback should be registered.
- **callback** – [in] The callback invoked whenever any target tracked on *locality* transitions between *activity_state::inactive* and *activity_state::active*.
- **epoch_filter** – [in] If set, restricts notifications to transitions recorded under this epoch; see the asynchronous overload for details, including how this applies to the registration-time replay.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

hpx::exception – if *locality* does not represent a locality, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_activity_observer() in order to stop receiving notifications.

hpx::id_type *hpx*::*supervision*::**register_activity_observer**(activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe activity-state transitions of all targets tracked on the local locality.

Note

> As for the remote overloads, for every target on the local locality that is already `activity_state::active` at registration time, one `activity_transition::` already_active replay notification is delivered synchronously as part of this call, taken under the same lock that serializes activity-state transitions, so the observer can neither miss nor double-receive any active target's current activity state.

Parameters

- **`callback`** – [in] The callback invoked whenever any target tracked on the local locality transitions between *activity_state::inactive* and *activity_state::active*.
- **`epoch_filter`** – [in] If set, restricts notifications to transitions recorded under this epoch, including the registration-time replay; see the remote overload for details. If `std::nullopt` (the default), the observer is notified regardless of epoch.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if the operation fails, unless *ec* was initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_activity_observer() in order to stop receiving notifications.

hpx::supervision::unregister_activity_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

- *hpx::supervision::register_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<void> `hpx::supervision::unregister_activity_observer`(*hpx*::id_type const &locality, *hpx*::id_type const &observer_handle)

Unregister a previously registered activity observer on a possibly remote locality.

> **Note**
>
> Once the returned future has become ready, no orphaned callbacks fire after unregistration completes.

Parameters

- **locality** – [in] The locality on which the observer was registered.
- **observer_handle** – [in] The handle returned by a prior call to register_activity_observer(). Only handles returned from that function are accepted; passing a handle obtained from register_observer() (or any foreign handle) is rejected.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid activity-observer handle. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once the observer has been unregistered.

void `hpx::supervision::unregister_activity_observer`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered activity observer on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of *unregister_activity_observer*(hpx::id_type const&, hpx::id_type const&).

> **Note**
>
> No orphaned callbacks fire after unregistration completes.

Parameters

- **locality** – [in] The locality on which the observer was registered.
- **observer_handle** – [in] The handle returned by a prior call to register_activity_observer(). See the asynchronous overload regarding foreign handles.
- **ec** – [in,out] this represents the error status on exit, if this pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid activity-observer handle, unless *ec* was initialized not to *hpx::throws*.

void `hpx::supervision::unregister_activity_observer`(*hpx*::id_type const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered activity observer on the local locality.

> **Note**
>
> No orphaned callbacks fire after unregistration completes.

Parameters

- **observer_handle** – [in] The handle returned by a prior call to register_activity_observer(). Must be local to the calling locality. See the remote overload regarding foreign handles.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *observer_handle* does not represent a valid activity-observer handle, unless *ec* was not pre-initialized to *hpx::throws*.

hpx::supervision::check_admission

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

dispatch_outcome `hpx::supervision::`**`check_admission`**(*hpx*::id_type const &target, *std*::uint64_t epoch = 0)

Check whether *target* currently admits new dispatch under *epoch*.

Queries the local supervision manager's terminal-latch state for *target* within *epoch*, i.e. the same state maintained by publish_event() and consulted by await_terminal(). Does not publish, mutate state, or notify observers.

> **Note**
>
> This is a pure local read of already-resident latch state, not a query that can fail the way a remote publish_event() call can; it never throws and carries no hpx::error_code out-parameter.

Note

The terminal latch consulted here is populated only by publish_event() calls delivered to *this* locality's supervision manager for *target*. It is not synchronized across localities: a terminal event published to a different locality's manager for the same logical target/epoch is invisible here and does not affect this call's outcome. `register_observer` / `unregister_observer` notifications do not feed this state either. Any locality other than the one hosting *target's* supervision manager that needs to gate its own dispatch decisions on *target's* terminal state must build that cross-locality propagation itself (e.g. registering an observer with the owning locality and re-publishing locally, or routing the admission decision to the owning locality); this API provides no such mechanism.

Parameters

- **`target`** – [in] The actor (or component) to check. Must be local to the calling locality.
- **`epoch`** – [in] The epoch dispatch would occur under.

Returns

`dispatch_outcome::rejected_fenced` if *target* has already latched a terminal event (`completed` or `failed`) under *epoch*, `dispatch_outcome::admitted` otherwise (including when *target* is unknown locally or invalid).

hpx::supervision::await_terminal

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::is_valid_transition*

```
hpx::future<lifecycle_state> hpx::supervision::await_terminal(hpx::id_type const &locality, hpx::id_type const &target, std::uint64_t epoch = 0, std::optional<std::chrono::steady_clock::duration> timeout = std::nullopt)
```

Asynchronously wait for a target actor on a possibly remote locality to reach a terminal lifecycle event (`completed` or `failed`) within a given epoch.

The function await_terminal() is a one-shot, blocking-free counterpart to register_observer() for the specific case of waiting on the terminal transition: unlike an observer, it does not need to be explicitly unregistered, but it also only ever resolves once, for the exact (*target*, *epoch*) pair passed in.

> **Note**
>
> below for this call only. If `std::nullopt` (the default), *locality's* current default timeout is used instead.

> **Note**
>
> below).

> **Note**
>
> *locality* bounds the lifetime of every waiter it registers on behalf of an outstanding call, so dropping the returned future without *target* ever reaching a terminal event under *epoch* does not leak the corresponding waiter entry indefinitely: it is swept and invalidated at or after *timeout* elapses, enforced by a background timer on *locality* independently of any further activity for *target*, so an idle target's waiter is not left to accumulate until some later, unrelated call happens to sweep it. Callers that need a tighter bound than *timeout* should still race the returned future against an external timeout.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) to wait on.
- **`epoch`** – [in] The epoch *target* must reach a terminal event under for the returned future to resolve. If *target's* epoch is later superseded by a higher epoch (see the epoch semantics of *publish_event*) before it reaches a terminal event under *epoch*, the returned future becomes exceptional (see
- **`timeout`** – [in] Overrides the server-enforced timeout described in

Throws

- `below)` – instead of ever resolving with a value.
- *`hpx::exception`* – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional with a *hpx::error::stale_state* exception, naming *target*, *epoch*, and the epoch that superseded it, if *target's* epoch advances past *epoch* before reaching a terminal event under it. It also becomes exceptional with a *hpx::error::future_cancelled* exception if neither of the above happens before *timeout* elapses (see

Returns

A future that becomes ready, holding the *lifecycle_state* recorded for *target*, as soon as *target* reaches a terminal event under *epoch*. If *target* has already reached a terminal event under *epoch* at the time of the call, the returned future is ready immediately.

lifecycle_state `hpx::supervision::await_terminal`(*hpx*::*launch*::sync_policy, *hpx*::id_type const &locality, *hpx*::id_type const &target, *std*::uint64_t epoch = 0, *std*::optional<*std*::chrono::steady_clock::duration> timeout = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Wait for a target actor on a possibly remote locality to reach a terminal lifecycle event, blocking until it does.

This is the synchronous equivalent of *await_terminal*(hpx::id_type const&, hpx::id_type const&, std::uint64_t).

> **Note**
>
> This call blocks until *target* reaches a terminal event, its epoch is superseded, or *timeout* elapses.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) to wait on.
- **`epoch`** – [in] The epoch *target* must reach a terminal event under. See the asynchronous overload for details.
- **`timeout`** – [in] Overrides the server-enforced timeout described in the asynchronous overload for this call only. If `std::nullopt` (the default), *locality's* current default timeout is used instead.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*. Also throws (or sets *ec* to) a *hpx::error::stale_state* exception, naming *target*, *epoch*, and the epoch that superseded it, if *target's* epoch advances past *epoch* before reaching a terminal event under it. Also throws (or sets *ec* to) a *hpx::error::future_cancelled* exception if neither of the above happens before *timeout* elapses.

Returns

The *lifecycle_state* recorded for *target* once it reaches a terminal event under *epoch*.

hpx::*future*<lifecycle_state> `hpx::supervision::await_terminal`(*hpx*::id_type const &target, *std*::uint64_t epoch = 0, *std*::optional<*std*::chrono::steady_clock::duration> timeout = *std*::nullopt)

Asynchronously wait for a target actor on the local locality to reach a terminal lifecycle event within a given epoch.

> **Note**
>
> As for the remote overloads, the returned future becomes exceptional with *hpx::error::stale_state* if *epoch* is superseded, or with *hpx::error::future_cancelled* if *timeout* elapses first.

Parameters

- **`target`** – [in] The actor (or component) to wait on. Must be local to the calling locality.
- **`epoch`** – [in] The epoch *target* must reach a terminal event under. See the remote overload for details.
- **`timeout`** – [in] Overrides the server-enforced timeout described in the asynchronous overload for this call only. If `std::nullopt` (the default), the local locality's default timeout is used instead.

Returns

A future that becomes ready, holding the *lifecycle_state* recorded for *target*, as soon as *target* reaches a terminal event under *epoch*. See the remote overload for how the returned future behaves if *target's* epoch is superseded before reaching a terminal event under *epoch*.

lifecycle_state *hpx*::*supervision*::**await_terminal**(*hpx*::*launch*::sync_policy, *hpx*::id_type const &target, *std*::uint64_t epoch = 0, *std*::optional<*std*::chrono::steady_clock::duration> timeout = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Synchronously wait for a local supervised target to reach a terminal lifecycle state (`completed` or `failed`).

This overload is restricted to targets that are guaranteed to be local to the calling locality. Because no dispatch/AGAS round-trip is required, it is cheaper than the remote `hpx::launch::sync_policy` overload and simply blocks the calling thread on the underlying local future.

Parameters

- **`target`** – The id of the supervised entity to wait on. Must refer to a component that is local to this locality.
- **`epoch`** – The join/generation epoch the caller expects `target` to still be part of. Passing an epoch that no longer matches the target's current epoch may cause the wait to resolve immediately with a mismatch-related error.
- **`timeout`** – Optional upper bound on how long to wait before giving up. If not supplied, uses the local supervision manager's default timeout.
- **`ec`** – Used to report errors instead of throwing an exception. When `target` does not represent a valid id, `hpx::error::bad_parameter` is reported. If the wait is cancelled due to `timeout` elapsing without a terminal state being reached, `hpx::error::future_cancelled` is reported.

Throws

hpx::exception – if `ec` is `hpx::throws` (the default) and an error is encountered; otherwise sets `ec` to reflect the error and returns.

Returns

The terminal `lifecycle_state` observed for `target`, or a default-constructed `lifecycle_state` if an error occurred and `ec` was used to report it.

hpx::supervision::is_valid_transition

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*

bool *hpx*::*supervision*::**is_valid_transition**(event from, event to) noexcept

Determine whether transitioning from lifecycle event *from* to lifecycle event *to* is permitted by the supervision lifecycle state machine.

event::completed and *event::failed* are terminal states and have no outgoing transitions. *event::losing_locality* is only reachable from *event::started*, *event::running*, or *event::suspending*, and may only transition to *failed*. A missing prior event is represented as *event::unknown*, from which the only valid transition is to *event::started*.

hpx::supervision::testing::set_register_observer_snapshot_hook

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

void *hpx*::*supervision*::testing::**set_register_observer_snapshot_hook**(*std*::function<void()> hook)

Set the hook invoked after an observer snapshot is captured.

> **Note**
>
> Used for testing purposes only.

Parameters

hook – Hook to invoke. An empty function clears the hook.

hpx::supervision::supervision_manager

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **supervision_manager**

hpx/supervision/server/supervision_manager.hpp

Defined in header hpx/supervision/server/supervision_manager.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

void **register_server_instance**(char const *service_name, *std*::uint32_t locality_id, *error_code* &ec = *throws*)

void **unregister_server_instance**(*error_code* &ec = *throws*) const

publish_result **publish_event**(*hpx*::id_type const &target, event ev, *std*::uint64_t epoch)

Applies epoch/terminal-latch state-mutation rules, resolves any await_terminal() waiters affected by the transition, and invokes registered per-target lifecycle observers and activity observers for this call.

Parameters

- **target** – Target whose supervision state is updated. Must live on this locality.
- **ev** – Lifecycle event to apply.
- **epoch** – Epoch associated with `ev`.

Returns

The result of applying `ev` to target's state.

lifecycle_state **query_state**(*hpx*::id_type const &target)

hpx::id_type **register_observer**(*hpx*::id_type const &target, *hpx*::id_type const &agent, *std*::uint64_t epoch_filter = static_cast<*std*::uint64_t>(-1))

void **unregister_observer**(*hpx*::id_type const &observer_handle)

void **remove_target**(*hpx*::id_type const &target)

Clears all locally tracked state for `target`.

Unlike unregister_observer(), which removes a single previously registered observer handle (and leaves any recorded lifecycle state for its target(s) intact), *remove_target()* unconditionally forgets every piece of local bookkeeping this supervision manager holds for `target` - its recorded lifecycle state and current epoch (see *publish_event()*), and any per-target observers still registered for it (see register_observer()) - regardless of any specific observer handle. Intended for callers that know `target` will never be queried or observed again locally (e.g. after a failed registration that seeded some state for it, or once a peer has been evicted) and want to reclaim that local state instead of letting it accumulate indefinitely.

void **tidy**()

Unconditionally clears all locally tracked state.

Snapshots every target currently present in states_ or observers_ under mtx_, releases the lock, then calls *remove_target()* for each one in turn, reusing its existing per-target teardown (waiter invalidation, activity-observer notifications, agent/state cleanup) instead of duplicating that logic here. Targets added concurrently with (or after) the snapshot are left untouched. If states_ and observers_ are empty at snapshot time, this is a no-op: *tidy()* never reports an error and never fires any notification of its own for the "nothing to do" case. Local-only: unlike *remove_target()*, this is not exposed as a remote action.

hpx::id_type **register_activity_observer**(*hpx*::id_type const &agent, *std*::uint64_t epoch_filter = static_cast<*std*::uint64_t>(-1))

Registers a locality-scoped activity observer.

Replays targets that are already active when registration takes its snapshot.

The snapshot of the target's tracked state and the insertion of the observer into the tracked set happen atomically under `mtx_`, which guarantees the observer receives exactly one notification for the target's current state: either the replay (if already active at registration time) or a live transition that raced with registration, but never both and never neither.

Delivery of that notification (replay or live) happens after `mtx_` is released and is therefore not ordered relative to any other concurrent live notification for the same target; callers must not assume replay is delivered before or after a racing live event.

void **unregister_activity_observer**(*hpx*::id_type const &observer_handle)

Unregisters an activity observer.

The handle must have been returned by *register_activity_observer()*. As with unregister_observer(), no orphaned callbacks fire after this call completes. `observer_handle` must have been returned by *register_activity_observer()*; a handle returned by register_observer() instead (i.e. found in agents_ rather than activity_observers_) is rejected.

hpx::*future*<lifecycle_state> **await_terminal**(*hpx*::id_type const &target, *std*::uint64_t epoch = 0, *std*::chrono::steady_clock::duration timeout = (*std*::chrono::steady_clock::duration::max)())

[599] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/experimental/task_group.hpp

[600] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/task_block.hpp

[601] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/task_block.hpp

object of type *task_block* and pass a reference to that object to a user-provided callable object.

An object of class task_block cannot be constructed, destroyed, copied, or moved except by the implementation of the task region library. Taking the address of a *task_block* object via operator& or addressof is ill formed. The result of obtaining its address by any other means is unspecified.

A task_block is active if it was created by the nearest enclosing task block, where "task block" refers to an invocation of define_task_block or define_task_block_restore_thread and "nearest

enclosing" means the most recent invocation that has not yet completed. Code designated for execution in another thread by means other than the facilities in this section (e.g., using thread or async) are not enclosed in the task region and a *task_block* passed to (or captured by) such code is not active within that code. Performing any operation on a *task_block* that is not active results in undefined behavior.

The task_block that is active before a specific call to the run member function is not active within the asynchronous function that invoked run. (The invoked function should not, therefore, capture the task_block from the surrounding block.)

```
Example:
   define_task_block([&](auto& tr) {
       tr.run([&] {
      ␣
↪    tr.run([] { f(); });              // Error: tr is not active
           define_task_block([&](auto& tr) { // Nested task block
     ␣
↪          tr.run(f);                   // OK: inner tr is active
               /// ...
           });
       }); /// ...
   });
```

Template Parameters

ExPolicy – The execution policy an instance of a task_block was created with. This defaults to *parallel_policy*.

hpx::experimental::define_task_block

Defined in header hpx/task_block.hpp[602].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::experimental::task_canceled_exception*
- *hpx::experimental::task_block*
- *hpx::experimental::define_task_block_restore_thread*

[602] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/task_block.hpp

Warning

doxygenfunction: Unable to resolve function “hpx::experimental::define_task_block” with arguments (ExPolicy&&, F&&) in doxygen xml output for project “hpx” from directory: ../hpx_autodoc. Potential matches:

```
- template<typename ExPolicy, typename␣
↪F> decltype(auto) define_task_block(ExPolicy &&policy, F &&f)
- template<typename F> void define_task_block(F &&f)
```

template<typename **F**>

void *hpx*::*experimental*::**define_task_block**(*F* &&f)

Constructs a task_block, tr, and invokes the expression *f(tr)* on the user-provided object, *f*. This version uses *parallel_policy* for task scheduling.

Postcondition: All tasks spawned from *f* have finished execution. A call to define_task_block may return on a different thread than that on which it was called.

Note

It is expected (but not mandated) that f will (directly or indirectly) call tr.run(*callable_object*).

Template Parameters

F – The type of the user defined function to invoke inside the define_task_block (deduced). *F* shall be MoveConstructible.

Parameters

f – The user defined function to invoke inside the task block. Given a lvalue *tr* of type task_block, the expression, (void)f(tr), shall be well-formed.

Throws

exception_list – specified in Exception Handling.

hpx::experimental::define_task_block_restore_thread

Defined in header hpx/task_block.hpp[603].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::experimental::task_canceled_exception*
- *hpx::experimental::task_block*
- *hpx::experimental::define_task_block*

template<typename **ExPolicy**, typename **F**>

[603] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/core/include_local/include/hpx/task_block.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> `hpx::experimental::define_task_block_restore_thread`(*ExPolicy* &&policy, *F* &&f)

Constructs a task_block, tr, and invokes the expression *f(tr)* on the user-provided object, *f*.

Postcondition: All tasks spawned from *f* have finished execution. A call to *define_task_block_restore_thread* always returns on the same thread as that on which it was called.

> **Note**
>
> It is expected (but not mandated) that f will (directly or indirectly) call tr.run(*callable_object*).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
- **F** – The type of the user defined function to invoke inside the define_task_block (deduced). *F* shall be MoveConstructible.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **f** – The user defined function to invoke inside the define_task_block. Given an lvalue *tr* of type task_block, the expression, (void)f(tr), shall be well-formed.

Throws

exception_list – specified in Exception Handling.

template<typename **F**>

void `hpx::experimental::define_task_block_restore_thread`(*F* &&f)

Constructs a task_block, tr, and invokes the expression *f(tr)* on the user-provided object, *f*. This version uses *parallel_policy* for task scheduling.

Postcondition: All tasks spawned from *f* have finished execution. A call to *define_task_block_restore_thread* always returns on the same thread as that on which it was called.

> **Note**
>
> It is expected (but not mandated) that f will (directly or indirectly) call tr.run(*callable_object*).

Template Parameters

F – The type of the user defined function to invoke inside the define_task_block (deduced). *F* shall be MoveConstructible.

Parameters

f – The user defined function to invoke inside the define_task_block. Given an lvalue *tr* of type task_block, the expression, (void)f(tr), shall be well-formed.

Throws

`exception_list` – specified in Exception Handling.

hpx/parallel/util/range.hpp

Defined in header hpx/parallel/util/range.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **parallel**

namespace **util**

Typedefs

template<typename **Iterator**, typename **Sentinel** = *Iterator*>

using **range** = *hpx*::*util*::iterator_range<*Iterator*, *Sentinel*>

Functions

template<typename **Iter**, typename **Sent**>

range<*Iter*, *Sent*> **concat**(*range*<*Iter*, *Sent*> const &it1, *range*<*Iter*, *Sent*> const &it2)

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**>

range<*Iter2*, *Iter2*> **init_move**(*range*<*Iter2*, *Sent2*> const &dest, *range*<*Iter1*, *Sent1*> const &src)

Move objects from the range src to dest.

Parameters

- **dest** – **[in]** : range where move the objects
- **src** – **[in]** : range from where move the objects

Returns
range with the objects moved and the size adjusted

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**>

range<*Iter2*, *Sent2*> **uninit_move**(*range*<*Iter2*, *Sent2*> const &dest, *range*<*Iter1*, *Sent1*> const &src)

Move objects from the range src creating them in dest.

Parameters

- **dest** – **[in]** : range where move and create the objects
- **src** – **[in]** : range from where move the objects

Returns
range with the objects moved and the size adjusted

template<typename **Iter**, typename **Sent**>

void **destroy_range**(*range*<*Iter*, *Sent*> r)

destroy a range of objects

Parameters
r – **[in]** : range to destroy

template<typename **Iter**, typename **Sent**>

range<*Iter*, *Sent*> **init**(*range*<*Iter*, *Sent*> const &r, typename *std*::iterator_traits<*Iter*>::value_type &val)

initialize a range of objects with the object val moving across them

Parameters

- **r** – **[in]** : range of elements not initialized
- **val** – **[in]** : object used for the initialization

Returns
range initialized

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>

bool **is_mergeable**(*range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

: indicate if two ranges have a possible merge

Remark

Parameters

- **src1** – **[in]** : first range
- **src2** – **[in]** : second range
- **comp** – **[in]** : object for to compare elements

Returns
true : they can be merged false : they can’t be merged

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Iter3**, typename **Sent3**, typename **Compare**>

range<*Iter3*, *Sent3*> **full_merge**(*range*<*Iter3*, *Sent3*> const &dest, *range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

Merge two contiguous ranges src1 and src2 , and put the result in the range dest, returning the range merged.

Parameters

- **dest** – **[in]** : range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2
- **src1** – **[in]** : first range to merge
- **src2** – **[in]** : second range to merge
- **comp** – **[in]** : comparison object

Returns

range with the elements merged and the size adjusted

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Value**, typename **Compare**>

range<*Value**> **uninit_full_merge**(*range*<*Value**> const &dest, *range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

Merge two contiguous ranges src1 and src2 , and create and move the result in the uninitialized range dest, returning the range merged.

Parameters

- **dest** – **[in]** : range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2. Initially is un-initialize memory
- **src1** – **[in]** : first range to merge
- **src2** – **[in]** : second range to merge
- **comp** – **[in]** : comparison object

Returns

range with the elements merged and the size adjusted

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>

range<*Iter2*, *Sent2*> **half_merge**(*range*<*Iter2*, *Sent2*> const &dest, *range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

: Merge two buffers. The first buffer is in a separate memory

Parameters

- **dest** – **[in]** : range where finish the two buffers merged
- **src1** – **[in]** : first range to merge in a separate memory
- **src2** – **[in]** : second range to merge, in the final part of the range where deposit the final results
- **comp** – **[in]** : object for compare two elements of the type pointed by the Iter1 and Iter2

Returns

: range with the two buffers merged

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Iter3**, typename **Sent3**, typename **Compare**>

bool **in_place_merge_uncontiguous**(*range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *range*<*Iter3*, *Sent3*> &aux, *Compare* comp)

: merge two non contiguous buffers src1 , src2, using the range aux as auxiliary memory

Remark

Parameters

- **src1** – **[in]** : first range to merge
- **src2** – **[in]** : second range to merge
- **aux** – **[in]** : auxiliary range used in the merge
- **comp** – **[in]** : object for to compare elements

Returns

true : not changes done false : changes in the buffers

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>

range<Iter1, Sent1> **in_place_merge**(*range<Iter1, Sent1>* const &src1, *range<Iter1, Sent1>* const &src2, *range<Iter2, Sent2>* &buf, *Compare* comp)

: merge two contiguous buffers (src1, src2) using buf as auxiliary memory

Remark

Parameters

- **src1** – **[in]** : first range to merge
- **src2** – **[in]** : second range to merge
- **buf** – **[in]** : auxiliary memory used in the merge
- **comp** – **[in]** : object for to compare elements

Returns

true : not changes done false : changes in the buffers

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>

void **merge_flow**(*range<Iter1, Sent1>* rng1, *range<Iter2, Sent2>* rbuf, *range<Iter1, Sent1>* rng2, *Compare* cmp)

hpx::shift_left

Defined in header hpx/algorithm.hpp[604].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter**, typename **Size**>

[604] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

FwdIter `hpx::shift_left`(*FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i.

The assignment operations in the parallel *shift_left* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: At most (last - first) - n assignments.

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of positions to shift by.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`n`** – Refers to the number of positions to shift.

Returns

The *shift_left* algorithm returns *FwdIter*. The *shift_left* algorithm returns an iterator to the end of the resulting range. Specifically: If *n* is 0 or *n* >= (last - first), does nothing and returns *last* and *first* respectively. Otherwise returns *first* + ((last - first) - n).

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Size`**>

hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*> `hpx::shift_left`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i. Executed according to the policy.

The assignment operations in the parallel *shift_left* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift_left* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most (last - first) - n assignments.

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of positions to shift by.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`n`** – Refers to the number of positions to shift.

Returns

The *shift_left* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *shift_left* algorithm returns an iterator to the end of the resulting range. Specifically: If *n* is 0, does nothing and returns *last*. If *n* >= (last - first), does nothing and returns *first*. Otherwise returns *first* + ((last - first) - n).

hpx::reduce_deterministic

Defined in header hpx/algorithm.hpp[605].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`F`**, typename **`T`** = typename *std*::iterator_traits<*FwdIter*>::value_type>

[605] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::reduce_deterministic`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init, *F* &&f)

Returns GENERALIZED_SUM(f, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *f*.

> **Note**
>
> GENERALIZED_SUM(op, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>

util::detail::algorithm_result_t<*ExPolicy*, *T*> hpx::**reduce_deterministic**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1

- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter**>

hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::value_type>::type `hpx::reduce_determinis`

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the operator+().

> **Note**
>
> The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

> **Note**
>
> GENERALIZED_SUM(+, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns T otherwise (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **FwdIter**, typename **F**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>

T *hpx*::**reduce_deterministic**(*FwdIter* first, *FwdIter* last, *T* init, *F* &&f)

Returns GENERALIZED_SUM(f, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *f*.

> **Note**
>
> GENERALIZED_SUM(op, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns *T*. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>

T *hpx*::**reduce_deterministic**(*FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the operator+().

> **Note**
>
> GENERALIZED_SUM(+, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *T*. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **FwdIter**>

std::iterator_traits<*FwdIter*>::value_type `hpx::reduce_deterministic`(*FwdIter* first, *FwdIter* last)

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

`FwdIter` – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns *T* (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

hpx::exclusive_scan

Defined in header hpx/algorithm.hpp[606].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **OutIter**, typename **T**>

OutIter `hpx::exclusive_scan`(*InIter* first, *InIter* last, *OutIter* dest, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, …, *(first + (i - result) - 1))

The reduce operations in the parallel *exclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *std::plus<T>*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aK)
- GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

[606] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.

Returns

The *exclusive_scan* algorithm returns *OutIter*. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **T**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> *hpx*::**exclusive_scan**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, …, *(first + (i - result) - 1))

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *std::plus*<*T*>.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:
>
> - a1 when N is 1
> - GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aK)
> - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- `FwdIter2` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- `T` – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `init` – The initial value for the generalized sum.

Returns

The *exclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **T**, typename **Op**>

OutIter `hpx::exclusive_scan`(*InIter* first, *InIter* last, *OutIter* dest, *T* init, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, …, *(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *op*.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:
>
> - a1 when N is 1
> - op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *exclusive_scan* algorithm returns *OutIter*. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Op**, typename **T**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> hpx::**exclusive_scan**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* init, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, …, *(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *op*.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:
>
> - a1 when N is 1
> - op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Op`** – The type of the binary function object used for the reduction operation.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`init`** – The initial value for the generalized sum.
- **`op`** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *exclusive_scan* algorithm returns a *hpx::future<OutIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *OutIter* otherwise. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::swap_ranges

Defined in header hpx/algorithm.hpp[607].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter1**, typename **FwdIter2**>

FwdIter2 `hpx::swap_ranges`(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Exchanges elements between range [first1, last1) and another range starting at *first2*.

The swap operations in the parallel *swap_ranges* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear in the distance between *first1* and *last1*.

Template Parameters

- **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

Returns

The *swap_ranges* algorithm returns *FwdIter2*. The *swap_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

[607] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::swap_ranges`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Exchanges elements between range [first1, last1) and another range starting at *first2*. Executed according to the policy.

The swap operations in the parallel *swap_ranges* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The swap operations in the parallel *swap_ranges* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Linear in the distance between *first1* and *last1*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the swap operations.
- **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

Returns

The *swap_ranges* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel_task_policy* and returns *FwdIter2* otherwise. The *swap_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

hpx::stable_sort

Defined in header hpx/algorithm.hpp[608].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandomIt**, typename **Comp** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::identity>

void *hpx*::**stable_sort**(*RandomIt* first, *RandomIt* last, *Comp* &&comp = *Comp*(), *Proj* &&proj = *Proj*())

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The assignments in the parallel *stable_sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *stable_sort* algorithm returns *void*.

[608] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

template<typename **ExPolicy**, typename **RandomIt**, typename **Comp** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::identity>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **hpx::stable_sort**(*ExPolicy* &&policy, *RandomIt* first, *RandomIt* last, *Comp* &&comp = *Comp*(), *Proj* &&proj = *Proj*())

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *stable_sort* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::unique

Defined in header hpx/algorithm.hpp[609].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::unique_copy*

template<typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to, typename **Proj** = *hpx*::identity>

FwdIter `hpx::unique`(*FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to std::equal_to<>
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

[609] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique* algorithm returns *FwdIter*. The *unique* algorithm returns the iterator to the new end of the range.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to, typename **Proj** = *hpx*::identity>

parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*>::type **hpx::unique**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range. Executed according to the policy.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *unique* algorithm returns the iterator to the new end of the range.

hpx::unique_copy

Defined in header hpx/algorithm.hpp[610].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::unique*

template<typename **InIter**, typename **OutIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to, typename **Proj** = *hpx*::identity>

OutIter `hpx::unique_copy`(*InIter* first, *InIter* last, *OutIter* dest, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

[610] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique_copy* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a, const Type &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique_copy* algorithm returns a returns *OutIter*. The *unique_copy* algorithm returns the destination iterator to the end of the *dest* range.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *hpx*::*parallel*::detail::equal_to, typename **Proj** = *hpx*::identity>

parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type **hpx::unique_copy**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied. Executed according to the policy.

The assignments in the parallel *unique_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique_copy* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a, const Type &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *unique_copy* algorithm returns the pair of the source iterator to *last*, and the destination iterator to the end of the *dest* range.

hpx::merge

Defined in header hpx/algorithm.hpp[611].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::inplace_merge*

template<typename **ExPolicy**, typename **RandIter1**, typename **RandIter2**, typename **RandIter3**, typename **Comp** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *RandIter3*> `hpx::merge`(*ExPolicy* &&policy, *RandIter1* first1, *RandIter1* last1, *RandIter2* first2, *RandIter2* last2, *RandIter3* dest, *Comp* &&comp = *Comp*())

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at *dest*. The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges. Executed according to the policy.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison *comp* and each projection.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

[611] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter1* and *RandIter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *merge* algorithm returns a *hpx::future<RandIter3> >* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandIter3* otherwise. The *merge* algorithm returns the destination iterator to the end of the *dest* range.

template<typename **RandIter1**, typename **RandIter2**, typename **RandIter3**, typename **Comp** = *hpx*::*parallel*::detail::less>

RandIter3 **hpx::merge**(*RandIter1* first1, *RandIter1* last1, *RandIter2* first2, *RandIter2* last2, *RandIter3* dest, *Comp* &&comp = *Comp*())

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at *dest*. The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

Note

Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison *comp* and each projection.

Template Parameters

- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.

- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter1* and *RandIter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *merge* algorithm returns a *RandIter3*. The *merge* algorithm returns the destination iterator to the end of the *dest* range.

hpx::inplace_merge

Defined in header hpx/algorithm.hpp[612].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::merge*

template<typename **ExPolicy**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **hpx::inplace_merge**(*ExPolicy* &&policy, *RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. Executed according to the policy.

The assignments in the parallel *inplace_merge* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

[612] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *inplace_merge* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs O(std::distance(first, last)) applications of the comparison *comp* and each projection.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`RandIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Comp`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **`middle`** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.
- **`comp`** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```
  bool comp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *inplace_merge* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns void otherwise. The *inplace_merge* algorithm returns the source iterator *last*.

template<typename **`RandIter`**, typename **`Comp`** = *hpx*::*parallel*::detail::less>

void *hpx*::**`inplace_merge`**(*RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

> **Note**
>
> Complexity: Performs O(std::distance(first, last)) applications of the comparison *comp* and each projection.

Template Parameters

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *inplace_merge* algorithm returns a *void*. The *inplace_merge* algorithm returns the source iterator *last*.

hpx::search

Defined in header hpx/algorithm.hpp[613].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::search_n*

template<typename **FwdIter**, typename **FwdIter2**, typename **Pred** = *parallel*::detail::equal_to>

[613] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

FwdIter `hpx::search`(*FwdIter* first, *FwdIter* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm execute in sequential order in the calling thread.

Note

Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to*<>

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *search* algorithm returns a *hpx::future*<*FwdIter*> if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **FwdIter2**, typename **Pred** = *parallel*::detail::equal_to>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **hpx::search**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to<>*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *search* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

template<typename **FwdIter**, typename **Searcher**>

FwdIter hpx::**search**(*FwdIter* first, *FwdIter* last, *Searcher* &&searcher)

Searches the range [first, last) using a searcher object.

Template Parameters

- **FwdIter** – The type of the source iterators (deduced). This iterator type must meet the requirements of a forward iterator.
- **Searcher** – A callable searcher object meeting the C++ Searcher requirements (e.g. std::boyer_moore_searcher).

Parameters

- **first** – Refers to the beginning of the sequence to search.
- **last** – Refers to the end of the sequence to search.
- **searcher** – A callable object performing the search.

Returns

An iterator to the beginning of the found subsequence, or *last* if no subsequence is found.

template<typename **ExPolicy**, typename **FwdIter**, typename **Searcher**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> hpx::**search**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Searcher* &&searcher)

Searches the range [first, last) using a searcher object. Executed according to the policy.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced).

- **FwdIter** – The type of the source iterators (deduced).
- **Searcher** – A callable searcher object meeting the C++ Searcher requirements.

Parameters

- **policy** – The execution policy to use.
- **first** – Refers to the beginning of the sequence to search.
- **last** – Refers to the end of the sequence to search.
- **searcher** – A callable object performing the search.

Returns

The algorithm returns a *hpx::future<FwdIter>* if the execution policy is a task policy, or *FwdIter* otherwise.

hpx::search_n

Defined in header hpx/algorithm.hpp[614].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::search*

template<typename **FwdIter**, typename **FwdIter2**, typename **Pred** = *parallel*::detail::equal_to>

FwdIter **hpx::search_n**(*FwdIter* first, *std*::size_t count, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search_n* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = count.

Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search_n* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to<>*

[614] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *search_n* algorithm returns *FwdIter*. The *search_n* algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **FwdIter2**, typename **Pred** = *parallel*::detail::equal_to>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **hpx::search_n**(*ExPolicy* &&policy, *FwdIter* first, *std*::size_t count, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel *search_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = count.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search_n* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to*<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *search_n* algorithm returns a *hpx::future*<*FwdIter*> if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *search_n* algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

hpx::experimental::reduction_bit_or

Defined in header hpx/algorithm.hpp[615].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_or<*T*>> `hpx::experimental::`**`reduction_bit_or`**(*T* &var)

The function template *reduction_bit_or* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::bit_or{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_bit_or* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::bit_or{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the

[615] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_or<*T*>> *hpx*::*experimental*::**reduction_bit_or**(*T* &var, *T* const &identity)

hpx::is_partitioned

Defined in header hpx/algorithm.hpp[616].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter**, typename **Pred**>

bool *hpx*::**is_partitioned**(*FwdIter* first, *FwdIter* last, *Pred* &&pred)

Determines if the range [first, last) is partitioned.

> **Note**
>
> Complexity: at most (N) predicate evaluations where *N* = distance(first, last).

Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

[616] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_partitioned* algorithm returns *bool*. The *is_partitioned* algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise is_partitioned returns false. If the range [first, last) contains less than two elements, the function is always true.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::is_partitioned`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred)

Determines if the range [first, last) is partitioned. Executed according to the policy.

The predicate operations in the parallel *is_partitioned* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is_partitioned* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: at most (N) predicate evaluations where *N* = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). *Pred* must be *Copy-Constructible* when using a parallel policy.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_partitioned* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task_execution_policy* and returns *bool* otherwise. The *is_partitioned* algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise is_partitioned returns false. If the range [first, last) contains less than two elements, the function is always true.

hpx::starts_with

Defined in header hpx/algorithm.hpp[617].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter1**, typename **InIter2**, typename **Pred** = *hpx*::*parallel*::detail::equal_to>

bool *hpx*::**starts_with**(*InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2)

The assignments in the parallel *starts_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- **InIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The binary predicate that compares the elements. This defaults to *hpx::parallel::detail::equal_to*.

Parameters

- **first1** – Refers to the beginning of the source range.

[617] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *starts_with* algorithm returns *bool*. The *starts_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

template<typename **ExPolicy**, typename **InIter1**, typename **InIter2**, typename **Pred** = *ranges*::equal_to>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> *hpx*::**starts_with**(*ExPolicy* &&policy, *InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2). Executed according to the policy.

The assignments in the parallel *starts_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **InIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The binary predicate that compares the elements. This defaults to *ranges::equal_to*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.

- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *starts_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *starts_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

hpx::uninitialized_copy

Defined in header hpx/algorithm.hpp[618].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_copy_n*

template<typename **InIter**, typename **FwdIter**>

FwdIter hpx::**uninitialized_copy**(*InIter* first, *InIter* last, *FwdIter* dest)

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized_copy* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

[618] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Returns

The *uninitialized_copy* algorithm returns *FwdIter*. The *uninitialized_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::`**`uninitialized_copy`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_copy* algorithm returns a *hpx::future<FwdIter2>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *uninitialized_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::uninitialized_copy_n

Defined in header hpx/algorithm.hpp[619].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_copy*

template<typename **InIter**, typename **Size**, typename **FwdIter**>

FwdIter `hpx::uninitialized_copy_n`(*InIter* first, *Size* count, *FwdIter* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized_copy_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_copy_n* algorithm returns a returns *FwdIter*. The *uninitialized_copy_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

[619] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

template<typename **ExPolicy**, typename **FwdIter1**, typename **Size**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::uninitialized_copy_n`(*ExPolicy* &&policy, *FwdIter1* first, *Size* count, *FwdIter2* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized_copy_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_copy_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_copy_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *uninitialized_copy_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::partial_sort_copy

Defined in header hpx/algorithm.hpp[620].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>

RandIter `hpx::partial_sort_copy`(*InIter* first, *InIter* last, *RandIter* d_first, *RandIter* d_last, *Comp* &&comp = *Comp*())

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d_first, d_last). At most d_last - d_first of the elements are placed sorted to the range [d_first, d_first + n) where n is the number of elements to sort (n = min(last - first, d_last - d_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(N log(min(D,N))), where N = std::distance(first, last) and D = std::distance(d_first, d_last) comparisons.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **RandIter** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **d_first** – Refers to the beginning of the destination range.
- **d_last** – Refers to the end of the destination range.

[620] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.

Returns

The *partial_sort_copy* algorithm returns a *RandomIt*. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. d_first + min(last - first, d_last - d_first)

template<typename **ExPolicy**, typename **FwdIter**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>

parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *RandIter*> `hpx::partial_sort_copy`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *RandIter* d_first, *RandIter* d_last, *Comp* &&comp = *Comp*())

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d_first, d_last). At most d_last - d_first of the elements are placed sorted to the range [d_first, d_first + n) where n is the number of elements to sort (n = min(last - first, d_last - d_first)). Executed according to the policy.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(N log(min(D,N))), where N = std::distance(first, last) and D = std::distance(d_first, d_last) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **RandIter** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **d_first** – Refers to the beginning of the destination range.
- **d_last** – Refers to the end of the destination range.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.

Returns

The *partial_sort_copy* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandomIt* otherwise. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. d_first + min(last - first, d_last - d_first)

hpx::inclusive_scan

Defined in header hpx/algorithm.hpp[621].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **OutIter**>

OutIter `hpx::`**`inclusive_scan`**(*InIter* first, *InIter* last, *OutIter* dest)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, *first, …, *(first + (i - result))).

The reduce operations in the parallel *inclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*, here std::plus<>().

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1

[621] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aK)
- GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *inclusive_scan* algorithm returns *OutIter*. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> hpx::inclusive_scan(ExPolicy &&policy,
                                                                                        FwdIter1 first,
                                                                                        FwdIter1 last,
                                                                                        FwdIter2 dest)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, *first, …, *(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *op*, here std::plus<>().

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK)
- GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **Op**>

OutIter hpx::**inclusive_scan**(*InIter* first, *InIter* last, *OutIter* dest, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, ..., *(first + (i - result))).

The reduce operations in the parallel *inclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *op*.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:
>
> - a1 when N is 1
> - GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK)
> - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *inclusive_scan* algorithm returns *OutIter*. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Op**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::inclusive_scan`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, …, *(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK)
- GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **Op**, typename **T**>

OutIter `hpx::`**`inclusive_scan`**(*InIter* first, *InIter* last, *OutIter* dest, *Op* &&op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, …, *(first + (i - result))).

The reduce operations in the parallel *inclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *op*.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:
>
> - a1 when N is 1
> - op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.
- **init** – The initial value for the generalized sum.

Returns

The *inclusive_scan* algorithm returns *OutIter*. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Op**, typename **T**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> hpx::**inclusive_scan**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, …, *(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, . . . , aN)) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.
- **init** – The initial value for the generalized sum.

Returns

The *inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::uninitialized_value_construct

Defined in header hpx/algorithm.hpp[622].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_value_construct_n*

template<typename **FwdIter**>

void *hpx*::**uninitialized_value_construct**(*FwdIter* first, *FwdIter* last)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_value_construct* algorithm returns nothing

template<typename **ExPolicy**, typename **FwdIter**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> *hpx*::**uninitialized_value_construct**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized_value_construct* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_value_construct* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to

[622] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_value_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns nothing otherwise.

hpx::uninitialized_value_construct_n

Defined in header hpx/algorithm.hpp[623].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_value_construct*

template<typename **FwdIter**, typename **Size**>

FwdIter hpx::**uninitialized_value_construct_n**(*FwdIter* first, *Size* count)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

[623] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_value_construct_n* algorithm returns a returns *FwdIter*. The *uninitialized_value_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::uninitialized_value_construct_n`(*ExPolicy* &&policy, *FwdIter* first, *Size* count)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized_value_construct_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_value_construct_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_value_construct_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_value_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

hpx::equal

Defined in header hpx/algorithm.hpp[624].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>

util::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::equal`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to the policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(min(*last1* - *first1*, *last2* - *first2*)) applications of the predicate *op*.

> **Note**
>
> The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

[624] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

util::detail::algorithm_result_t<*ExPolicy*, bool> **hpx::equal**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(min(*last1* - *first1*, *last2* - *first2*)) applications of the predicate *std::equal_to*.

> **Note**
>
> The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>

util::detail::algorithm_result_t<*ExPolicy*, bool> *hpx*::**equal**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(min(*last1* - *first1*, *last2* - *first2*)) applications of the predicate *op*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

util::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::equal`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most *last1 - first1* applications of the predicate *op*.

> **Note**
>
> The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>

bool *hpx*::**equal**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

> **Note**
>
> Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op*.

> **Note**
>
> The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *bool* . The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **FwdIter1**, typename **FwdIter2**>

bool *hpx*::**equal**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

> **Note**
>
> Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *std::equal_to*.

> **Note**
>
> The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *equal* algorithm returns a *bool* . The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>

bool *hpx*::**equal**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range [first2, first2 + (last1 - first1)), and false otherwise.

Note

Complexity: At most *last1* - *first1* applications of the predicate *op*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *bool* . The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

hpx::experimental::induction

Defined in header hpx/algorithm.hpp[625].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::induction_stride_helper<*T*> `hpx::experimental::induction`(*T* &&value, *std*::size_t stride)

The function template returns an induction object of unspecified type having a value type and encapsulating an initial *value* of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence *S* computes an induction value from an induction variable and ordinal position *p* within *S* by the formula i + p * stride if a stride was specified or i + p otherwise. This induction value is passed to the element access function.

If the *value* argument to *induction* is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of i + n * stride to the live-out object upon return, where *n* is the number of elements in the input range.

Template Parameters

T – The value type to be used by the induction object.

Parameters

- **value** – [in] The initial value to use for the induction object
- **stride** – [in] The (optional) stride to use for the induction object (default: 1)

Returns

This returns an induction object with value type *T*, initial *value*, and (if specified) *stride*. If *T* is a lvalue of non-const type, *value* is used as the live-out object for the induction object; otherwise there is no live-out object.

[625] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

template<typename **T**>

constexpr *hpx*::*parallel*::detail::induction_helper<*T*> `hpx::experimental::induction`(*T* &&value)

hpx::experimental::reduction

Defined in header hpx/algorithm.hpp[626].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **Op**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::decay_t<*Op*>> `hpx::experimental::reduction`(*T* &var, *T* const &identity, *Op* &&combiner)

The function template returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, a combiner function object, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses reduction objects by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the reduction object's combiner operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*. The expression

```
var = combiner(var, var)
```

shall be well-formed.

Note

[626] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation. For example if the combiner is plus<T>, incrementing the view would be consistent with the combiner but doubling it or assigning to it would not.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.
- **combiner** – [in] The binary function (object) used to perform a pairwise reduction on the elements.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**, typename **Op**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::decay_t<*Op*>> *hpx*::*experimental*::**reduction**(*T* &var, *Op* &&combiner)

hpx::mismatch

Defined in header hpx/algorithm.hpp[627].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>

[627] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> `hpx::mismatch`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator==* are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential

form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> **hpx::mismatch**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most min(last1 - first1, last2 - first2) applications of *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator==* are made.

> **Note**
>
> The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2*>> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> `hpx::mismatch`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most last1 - first1 applications of the predicate *op* or *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator*== are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> hpx::**mismatch**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most last1 - first1 applications of *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator*== are made.

> **Note**
>
> The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>

std::pair<*FwdIter1*, *FwdIter2*> `hpx::`**`mismatch`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator==* are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **FwdIter1**, typename **FwdIter2**>

std::pair<*FwdIter1*, *FwdIter2*> `hpx::mismatch`(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator*== are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>

std::pair<*FwdIter1*, *FwdIter2*> `hpx::mismatch`(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

Note

Complexity: At most last1 - first1 applications of the predicate *op* or *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator*== are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **FwdIter1**, typename **FwdIter2**>

std::pair<*FwdIter1*, *FwdIter2*> hpx::**mismatch**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

> **Note**
>
> Complexity: At most last1 - first1 applications of *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator*== are made.

> **Note**
>
> The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

hpx::uninitialized_default_construct

Defined in header hpx/algorithm.hpp[628].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_default_construct_n*

template<typename **FwdIter**>

void *hpx*::**uninitialized_default_construct**(*FwdIter* first, *FwdIter* last)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized_default_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_default_construct* algorithm returns nothing

template<typename **ExPolicy**, typename **FwdIter**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> *hpx*::**uninitialized_default_construct**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

[628] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *uninitialized_default_construct* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_default_construct* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_default_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns nothing otherwise.

hpx::uninitialized_default_construct_n

Defined in header hpx/algorithm.hpp[629].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_default_construct*

template<typename **FwdIter**, typename **Size**>

FwdIter hpx::**uninitialized_default_construct_n**(*FwdIter* first, *Size* count)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

[629] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_default_construct_n* algorithm returns a returns *FwdIter*. The *uninitialized_default_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::`**`uninitialized_default_construct_n`**(*ExPolicy* &&policy, *FwdIter* first, *Size* count)

Constructs objects of type typename iterator_traits<ForwardIt> ::value_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized_default_construct_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_default_construct_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_default_construct_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_default_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

hpx::ends_with

Defined in header hpx/algorithm.hpp[630].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter1**, typename **InIter2**, typename **Pred** = *hpx*::*parallel*::detail::equal_to>

bool *hpx*::**ends_with**(*InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2)

The assignments in the parallel *ends_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- **InIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

[630] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **InIter2** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a input iterator.
- **Pred** – The binary predicate that compares the elements. This defaults to *hpx::parallel::detail::equal_to*.

Parameters

- **first1** – Refers to the beginning of the source range.
- **last1** – Refers to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *ends_with* algorithm returns *bool*. The *ends_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *ranges*::equal_to>

hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, bool>::type **hpx::ends_with**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2). Executed according to the policy.

The assignments in the parallel *ends_with* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *ends_with* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **Pred** – The binary predicate that compares the elements. This defaults to *ranges::equal_to*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Refers to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *ends_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *ends_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

hpx::experimental::reduction_multiplies

Defined in header hpx/algorithm.hpp[631].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::multiplies<*T*>> `hpx::experimental::`**`reduction_multiplies`**`(`*T* &var)

The function template *reduction_multiplies* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::multiplies{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_multiplies* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::multiplies{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

[631] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Note

In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::multiplies<*T*>> `hpx::experimental::`**`reduction_multiplies`**(*T* &var, *T* const &identity)

hpx::min_element

Defined in header hpx/algorithm.hpp[632].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::max_element*
- *hpx::minmax_element*

template<typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>

FwdIter `hpx::`**`min_element`**(*FwdIter* first, *FwdIter* last, *F* &&f)

Finds the smallest element in the range [first, last) using the given comparison function *f*.

[632] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The comparisons in the parallel *min_element* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *min_element* algorithm returns *FwdIter*. The *min_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

template<typename **ExPolicy**, typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::min_element`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Finds the smallest element in the range [first, last) using the given comparison function *f*. Executed according to the policy.

The comparisons in the parallel *min_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *min_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *min_element* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *min_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *min_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

hpx::max_element

Defined in header hpx/algorithm.hpp[633].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::min_element*
- *hpx::minmax_element*

template<typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>

[633] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

FwdIter `hpx::max_element`(*FwdIter* first, *FwdIter* last, *F* &&f)

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min_element* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – The binary predicate which returns true if left argument is less than the right element. This argument is optional and defaults to std::less. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *max_element* algorithm returns *FwdIter*. The *max_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

template<typename **ExPolicy**, typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*>::type `hpx::max_element`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Removes all elements satisfying specific criteria from the range Finds the largest element in the range [first, last) using the given comparison function *f*. Executed according to the policy.

The comparisons in the parallel *max_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *max_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *max_element* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – The binary predicate which returns true if left argument is less than the right element. This argument is optional and defaults to std::less. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *max_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *max_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

hpx::minmax_element

Defined in header hpx/algorithm.hpp[634].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::min_element*
- *hpx::max_element*

template<typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>

minmax_element_result<*FwdIter*> *hpx*::**minmax_element**(*FwdIter* first, *FwdIter* last, *F* &&f)

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *minmax_element* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: At most *max*(floor(3/2*(N-1)), 0) applications of the predicate, where N = std::distance(first, last).

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *minmax_element* algorithm returns a *minmax_element_result<FwdIter>* The *minmax_element* algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns

[634] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

minmax_element_result<FwdIter>{first,first} if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, minmax_element_result<*FwdIter*>> `hpx::minmax_element`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *minmax_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *minmax_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most *max*(floor(3/2*(N-1)), 0) applications of the predicate, where N = std::distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *minmax_element* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *minmax_element* algorithm returns a hpx::future<*minmax_element_result*<*FwdIter*>> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *minmax_element_result*<*FwdIter*> otherwise. The *minmax_element* algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns *std::make_pair(first,first)* if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

hpx::experimental::reduction_plus

Defined in header hpx/algorithm.hpp[635].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::plus<*T*>> `hpx::experimental::reduction_plus`(*T* &var)

The function template *reduction_plus* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::plus{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_plus* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::plus{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

[635] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::plus<*T*>> *hpx*::*experimental*::**reduction_plus**(*T* &var, *T* const &identity)

hpx::experimental::reduction_bit_xor

Defined in header hpx/algorithm.hpp[636].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_xor<*T*>> *hpx*::*experimental*::**reduction_bit_xor**(*T* &var)

The function template *reduction_bit_xor* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::bit_xor{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

[636] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

A parallel algorithm uses the *reduction_bit_xor* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::bit_xor{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_xor<*T*>> *hpx*::*experimental*::**reduction_bit_xor**(*T* &var, *T* const &identity)

hpx::adjacent_find

Defined in header hpx/algorithm.hpp[637].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to>

InIter `hpx::adjacent_find`(*InIter* first, *InIter* last, *Pred* &&pred = *Pred*())

Searches the range [first, last) for two consecutive identical elements.

> **Note**
>
> Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

Template Parameters

- **InIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1* .

Returns

The *adjacent_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::adjacent_find`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate pred

637 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The comparison operations in the parallel *adjacent_find* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *adjacent_find* invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *adjacent_find* is available if the user decides to provide their algorithm their own binary predicate *pred*.

> **Note**
>
> Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **`pred`** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1* .

Returns

The *adjacent_find* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *adjacent_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

hpx::shift_right

Defined in header hpx/algorithm.hpp[638].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter**, typename **Size**>

FwdIter `hpx::shift_right`(*FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i.

The assignment operations in the parallel *shift_right* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: At most (last - first) - n assignments.

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

Returns

The *shift_right* algorithm returns *FwdIter*. The *shift_right* algorithm returns an iterator to the beginning of the resulting range. Specifically: If *n* is 0 or *n* >= (last - first), does nothing and returns *first* and *last* respectively. Otherwise returns *first* + n.

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>

[638] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*> **hpx::shift_right**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i. Executed according to the policy.

The assignment operations in the parallel *shift_right* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift_right* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most (last - first) - n assignments.

Note

The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

Returns

The *shift_right* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *shift_right* algorithm returns an iterator to the beginning of the resulting range. Specifically: If *n* is 0, does nothing and returns *first*. If *n* >= (last - first), does nothing and returns *last*. Otherwise returns *first* + n.

hpx::generate

Defined in header hpx/algorithm.hpp[639].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::generate_n*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::generate`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Assign each element in range [*first*, *last*) a value generated by the given function object *f*. Executed according to the policy.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

[639] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

Returns

The *generate* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise.

template<typename **FwdIter**, typename **F**>

void *hpx*::**generate**(*FwdIter* first, *FwdIter* last, *F* &&f)

Assign each element in range [*first*, *last*) a value generated by the given function object *f*.

> **Note**
>
> Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

Returns

The *generate* algorithm returns void.

hpx::generate_n

Defined in header hpx/algorithm.hpp[640].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::generate*

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**, typename **F**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::generate_n`(*ExPolicy* &&policy, *FwdIter* first, *Size* count, *F* &&f)

Assigns each element in range [*first*, *first+)* a value generated by the given function object *f*. Executed according to the policy.

The assignments in the parallel *generate_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Exactly *count* invocations of *f* and assignments, for count > 0.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.

[640] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

  ```
  Ret fun();
  ```

  The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

Returns
The *generate_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. *generate_n* algorithm returns iterator one past the last element assigned if count>0, first otherwise.

template<typename **FwdIter**, typename **Size**, typename **F**>

FwdIter hpx::**generate_n**(*FwdIter* first, *Size* count, *F* &&f)

Assigns each element in range [*first*, *first+)* a value generated by the given function object *f*.

> **Note**
>
> Complexity: Exactly *count* invocations of *f* and assignments, for count > 0.

Template Parameters

- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

  ```
  Ret fun();
  ```

  The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

Returns
The *generate_n* algorithm returns a *FwdIter*. *generate_n* algorithm returns iterator one past the last element assigned if count>0, first otherwise.

hpx/parallel/algorithms/iota.hpp

Defined in header hpx/parallel/algorithms/iota.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

template<typename **FwdIter**, typename **Sent**, typename **T**>

void **iota**(*FwdIter* first, *Sent* last, *T* value)

Fills the range [first, last) with sequentially increasing values, starting with *value* and repetitively evaluating ++`value`.

The assignments in the *iota* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Exactly *std::distance(first, last)* assignments and increments.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input or output iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **T** – The type of the value to be assigned (deduced). This type must be weakly incrementable.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be stored in the first element.

Returns

The *iota* algorithm returns *void*.

template<typename **ExPolicy**, typename **FwdIter**, typename **Sent**, typename **T**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **iota**(*ExPolicy* &&policy, *FwdIter* first, *Sent* last, *T* value)

Fills the range [first, last) with sequentially increasing values, starting with *value* and repetitively evaluating ++`value`.

The assignments in the parallel *iota* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *iota* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Exactly *std::distance(first, last)* assignments and increments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **T** – The type of the value to be assigned (deduced). This type must be weakly incrementable.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be stored in the first element.

Returns

The *iota* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::transform_inclusive_scan

Defined in header hpx/algorithm.hpp[641].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **OutIter**, typename **BinOp**, typename **UnOp**>

OutIter hpx::**transform_inclusive_scan**(*InIter* first, *InIter* last, *OutIter* dest, *BinOp* &&binary_op, *UnOp* &&unary_op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), …, conv(*(first + (i - result)))).

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum.

> **Note**
>
> Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:
>
> - a1 when N is 1
> - op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of *binary_op*.
- **UnOp** – The type of *unary_op*.

Parameters

[641] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `binary_op` – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- `unary_op` – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_inclusive_scan* algorithm returns a returns *OutIter*. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **BinOp**, typename **UnOp**>

parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type `hpx::transform_inclusive_scan`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *BinOp* &&binary_op, *UnOp* &&unary_op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), …, conv(*(first + (i - result)))). Executed according to the policy.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum.

> **Note**
>
> Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **BinOp** – The type of *binary_op*.
- **UnOp** – The type of *unary_op*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary_op** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- **unnary_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **BinOp**, typename **UnOp**, typename **T** = typename *std*::iterator_traits<*InIter*>::value_type>

OutIter hpx::**transform_inclusive_scan**(*InIter* first, *InIter* last, *OutIter* dest, *BinOp* &&binary_op, *UnOp* &&unary_op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, conv(*first), …, conv(*(first + (i - result)))).

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum. If *binary_op* is not mathematically associative, the behavior of *transform_inclusive_scan* may be non-deterministic.

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`BinOp`** – The type of *binary_op*.
- **`UnOp`** – The type of *unary_op*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`binary_op`** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- **`unnary_op`** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.
- **`init`** – The initial value for the generalized sum.

Returns

The *transform_inclusive_scan* algorithm returns a returns *OutIter*. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **BinOp**, typename **UnOp**, typename **T** = typename *std*::iterator_traits<*FwdIter1*>::value_type>

parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type `hpx::transform_inclusive_scan`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *BinOp* &&binary_op, *UnOp* &&unary_op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, conv(*first), …, conv(*(first + (i - result)))). Executed according to the policy.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum. If *binary_op* is not mathematically associative, the behavior of *transform_inclusive_scan* may be non-deterministic.

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1

- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of *binary_op*.
- **UnOp** – The type of *unary_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary_op** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- **unnary_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.
- **init** – The initial value for the generalized sum.

Returns

The *transform_inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::includes

Defined in header hpx/algorithm.hpp[642].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *hpx*::*parallel*::detail::less>

[642] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool>::type `hpx::includes`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*. Executed according to the policy.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> At most 2*(N1+N2-1) comparisons, where N1 = std::distance(first1, last1) and N2 = std::distance(first2, last2).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *includes* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *includes* algorithm returns true every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *hpx*::*parallel*::detail::less>

bool *hpx*::**includes**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*.

> **Note**
>
> At most 2*(N1+N2-1) comparisons, where N1 = std::distance(first1, last1) and N2 = std::distance(first2, last2).

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *includes* algorithm returns a *bool*. The *includes* algorithm returns true every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty.

hpx::partial_sort

Defined in header hpx/algorithm.hpp[643].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>

RandIter `hpx::partial_sort`(*RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

> **Note**
>
> Complexity: Approximately (last - first) * log(middle - first) comparisons.

Template Parameters

- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first

[643] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to detail::less.

Returns

The *partial_sort* algorithm returns a *RandIter* that refers to *last*.

template<typename **ExPolicy**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>

parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *RandIter*> **hpx::partial_sort**(*ExPolicy* &&policy, *RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

> **Note**
>
> Complexity: Approximately (last - first) * log(middle - first) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to detail::less.

Returns

The *partial_sort* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandIter* otherwise. The iterator returned refers to *last*.

hpx::adjacent_difference

Defined in header hpx/algorithm.hpp[644].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter1**, typename **FwdIter2**>

FwdIter2 `hpx::adjacent_difference`(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first.

> **Note**
>
> Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.

Returns

The *adjacent_difference* algorithm returns a *FwdIter2*. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::adjacent_difference`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first. Executed according to the policy.

[644] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.

Returns

The *adjacent_difference* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Op**>

FwdIter2 hpx::**adjacent_difference**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first

> **Note**
>
> Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent_difference* requires *Op* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **op** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

  ```
  bool op(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter1* can be dereferenced and then implicitly converted to the dereferenced type of *dest*.

Returns

The *adjacent_difference* algorithm returns *FwdIter2*. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Op**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> **hpx::adjacent_difference**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent_difference* requires *Op* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **op** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter1* can be dereferenced and then implicitly converted to the dereferenced type of *dest*.

Returns

The *adjacent_difference* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

hpx::copy

Defined in header hpx/algorithm.hpp[645].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::copy_n*
- *hpx::copy_if*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> **hpx::copy**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Executed according to the policy.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last - first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

[645] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Returns

The *copy* algorithm returns a *hpx::future<FwdIter2> >* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2>* otherwise. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**>

FwdIter2 `hpx::copy`(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- `FwdIter1` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.

Returns

The *copy* algorithm returns a *FwdIter2* . The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

hpx::copy_n

Defined in header hpx/algorithm.hpp[646].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::copy*
- *hpx::copy_if*

template<typename **ExPolicy**, typename **FwdIter1**, typename **Size**, typename **FwdIter2**>

[646] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::copy_n`(*ExPolicy* &&policy, *FwdIter1* first, *Size* count, *FwdIter2* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. Executed according to the policy.

The assignments in the parallel *copy_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *copy_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *copy_n* algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

template<typename **FwdIter1**, typename **Size**, typename **FwdIter2**>

FwdIter2 `hpx::copy_n`(*FwdIter1* first, *Size* count, *FwdIter2* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *copy_n* algorithm returns a *FwdIter2* . The *copy_n* algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

hpx::copy_if

Defined in header hpx/algorithm.hpp[647].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::copy*
- *hpx::copy_n*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> **hpx::copy_if**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved. Executed according to the policy.

[647] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *copy_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *f*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.

Returns

The *copy_if* algorithm returns a *hpx::future<FwdIter2> >* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *copy_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>

FwdIter2 `hpx::copy_if`(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *f*.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.

Returns

The *copy_if* algorithm returns a *FwdIter2* . The *copy_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

hpx::experimental::reduction_bit_and

Defined in header hpx/algorithm.hpp[648].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_and<*T*>> `hpx::experimental::`**`reduction_bit_and`**(*T* &var)

The function template *reduction_bit_and* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::bit_and{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_bit_and* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::bit_and{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the

[648] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_and<*T*>> `hpx::experimental::reduction_bit_and`(*T* &var, *T* const &identity)

hpx::is_sorted

Defined in header hpx/algorithm.hpp[649].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_sorted_until*

template<typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>

bool `hpx::is_sorted`(*FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel *is_sorted* algorithm executes in sequential order in the calling thread.

> **Note**
>
> Complexity: at most (N+S-1) comparisons where *N* = distance(first, last). *S* = number of partitions

Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use.

Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

[649] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **`pred`** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

  ```
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_sorted* algorithm returns a *bool*. The *is_sorted* algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::`**`is_sorted`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Determines if the range [first, last) is sorted. Uses pred to compare elements. Executed according to the policy.

The comparison operations in the parallel *is_sorted* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is_sorted* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (N+S-1) comparisons where *N* = distance(first, last). *S* = number of partitions

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is_sorted* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_sorted* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task_execution_policy* and returns *bool* otherwise. The *is_sorted* algorithm returns a bool if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

hpx::is_sorted_until

Defined in header hpx/algorithm.hpp[650].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_sorted*

template<typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>

FwdIter hpx::**is_sorted_until**(*FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel *is_sorted_until* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

[650] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **Pred** – The type of an optional function/function object to use.

Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_sorted_until* algorithm returns a *FwdIter*. The *is_sorted_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*>::type `hpx::is_sorted_until`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator. Executed according to the policy.

The comparison operations in the parallel *is_sorted_until* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is_sorted_until* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is_sorted_until* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_sorted_until* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *is_sorted_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

hpx::make_heap

Defined in header hpx/algorithm.hpp[651].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **RndIter**, typename **Comp**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **hpx::make_heap**(*ExPolicy* &&policy, *RndIter* first, *RndIter* last, *Comp* &&comp)

Constructs a *max heap* in the range [first, last). Executed according to the policy.

The predicate operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *sequential_execution_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *parallel_execution_policy* or *parallel_task_execution_policy*

[651] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`RndIter`** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.
- **`Comp`** – Comparison function object (i.e. an object that satisfies the requirements of Compare) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

  ```
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  While the signature does not need to have const &, the function must not modify the objects passed to it and must be able to accept all values of type (possibly *const*) *Type1* and *Type2* regardless of value category (thus, *Type1* & is not allowed, nor is *Type1* unless for *Type1* a move is equivalent to a copy. The types *Type1* and *Type2* must be such that an object of type *RandomIt* can be dereferenced and then implicitly converted to both of them.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **`comp`** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

  ```
  bool comp(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to Type.

Returns

The *make_heap* algorithm returns a *hpx::future<void>* if the execution policy is of type *task_execution_policy* and returns *void* otherwise.

template<typename **`ExPolicy`**, typename **`RndIter`**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> `hpx::make_heap`(*ExPolicy* &&policy, *RndIter* first, *RndIter* last)

Constructs a *max heap* in the range [first, last). Uses the operator < for comparisons. Executed according to the policy.

The predicate operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *sequential_execution_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *parallel_execution_policy* or *parallel_task_execution_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

Returns

The *make_heap* algorithm returns a *hpx::future<void>* if the execution policy is of type *task_execution_policy* and returns *void* otherwise.

template<typename **RndIter**, typename **Comp**>

void `hpx::make_heap`(*RndIter* first, *RndIter* last, *Comp* &&comp)

Constructs a *max heap* in the range [first, last).

> **Note**
>
> Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

- `RndIter` – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.
- `Comp` – Comparison function object (i.e. an object that satisfies the requirements of Compare) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

  ```
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  While the signature does not need to have const &, the function must not modify the objects passed to it and must be able to accept all values of type (possibly *const*) *Type1* and *Type2* regardless of value category (thus, *Type1* & is not allowed, nor is *Type1* unless for *Type1* a move is equivalent to a copy. The types *Type1* and *Type2* must be such that an object of type *RandomIt* can be dereferenced and then implicitly converted to both of them.

Parameters

- `first` – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- `comp` – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

  ```
  bool comp(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to Type.

Returns

The *make_heap* algorithm returns a *void*.

template<typename **RndIter**>

void *hpx*::**make_heap**(*RndIter* first, *RndIter* last)

Constructs a *max heap* in the range [first, last).

> **Note**
>
> Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

`RndIter` – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

Returns

The *make_heap* algorithm returns a *void*.

hpx/parallel/algorithms/transform_reduce_binary.hpp

Defined in header hpx/parallel/algorithms/transform_reduce_binary.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::set_union

Defined in header hpx/algorithm.hpp[652].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter3*> **hpx::set_union**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), then all *m* elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (for *sequenced_task_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

[652] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_union* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter3* otherwise. The *set_union* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>

FwdIter3 `hpx::set_union`(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), then all *m* elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

The resulting range cannot overlap with either of the input ranges.

> **Note**
>
> Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_union* algorithm returns a *FwdIter3*. The *set_union* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::lexicographical_compare

Defined in header hpx/algorithm.hpp[653].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter1**, typename **InIter2**, typename **Pred** = *hpx*::*parallel*::detail::less>

bool *hpx*::**lexicographical_compare**(*InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred)

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical_compare* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

> **Note**
>
> Lexicographical comparison is an operation with the following properties
>
> - Two ranges are compared element by element
> - The first mismatching element defines which range is lexicographically *less* or *greater* than the other
> - If one range is a prefix of another, the shorter range is lexicographically *less* than the other
> - If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
> - An empty range is lexicographically *less* than any non-empty range
> - Two empty ranges are lexicographically *equal*

Template Parameters

653 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **InIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to

Returns

The *lexicographically_compare* algorithm returns a returns *bool* if the execution policy object is not passed in. The *lexicographically_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::`**`lexicographical_compare`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&pred)

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical_compare* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *lexicographical_compare* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

Note

Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically *less* or *greater* than the other
- If one range is a prefix of another, the shorter range is lexicographically *less* than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
- An empty range is lexicographically *less* than any non-empty range
- Two empty ranges are lexicographically *equal*

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to

Returns

The *lexicographically_compare* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *lexicographically_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

hpx::set_intersection

Defined in header hpx/algorithm.hpp[654].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter3*> `hpx::set_intersection`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (for *sequenced_task_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

[654] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_intersection* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_intersection* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter3* otherwise. The *set_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>

FwdIter3 **hpx::set_intersection**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

> **Note**
>
> Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_intersection* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_intersection* algorithm returns a *FwdIter3*. The *set_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::transform_exclusive_scan

Defined in header hpx/algorithm.hpp[655].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **OutIter**, typename **BinOp**, typename **UnOp**, typename **T** = typename *std*::iterator_traits<*InIter*>::value_type>

OutIter hpx::**transform_exclusive_scan**(*InIter* first, *InIter* last, *OutIter* dest, *T* init, *BinOp* &&binary_op, *UnOp* &&unary_op)

Transforms each element in the range [first, last) with *unary_op*, then computes an exclusive prefix sum operation using *binary_op* over the resulting range, with *init* as the initial value, and writes the results to the range beginning at *dest*. "exclusive" means that the i-th input element is not included in the i-th sum. Formally, assigns through each iterator i in [dest, d_first + (last - first)) the value of the generalized noncommutative sum of init, unary_op(*j)… for every j in [first, first + (i - d_first)) over binary_op, where generalized noncommutative sum GNSUM(op, a1, …, a N) is defined as follows:

- if N=1, a1
- if N > 1, op(GNSUM(op, a1, …, aK), GNSUM(op, aM, …, aN)) for any K where 1 < K+1 = M <= N In other words, the summation operations may be performed in arbitrary order, and the behavior is nondeterministic if *binary_op* is not associative.

The reduce operations in the parallel *transform_exclusive_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *unary_op* nor *binary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of transform_exclusive_scan may be non-deterministic for a non-associative predicate.

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN) where 1 < K+1 = M <= N.

[655] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of *binary_op*.
- **UnOp** – The type of *unary_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **binary_op** – Binary *FunctionObject* that will be applied to the result of *unary_op*, the results of other *binary_op*, and *init*.
- **unary_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_exclusive_scan* algorithm returns a returns *OutIter*. The *transform_exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **BinOp**, typename **UnOp**, typename **T** = typename *std*::iterator_traits<*FwdIter1*>::value_type>

parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type *hpx*::**transform_exclusive_scan**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* init, *BinOp* &&binary_op, *UnOp* &&unary_op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), …, conv(*(first + (i - result) - 1))). Executed according to the policy.

The reduce operations in the parallel *transform_exclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_exclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *unary_op* nor *binary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of transform_exclusive_scan may be non-deterministic for a non-associative predicate.

> **Note**
>
> Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:
>
> - a1 when N is 1
> - op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of *binary_op*.
- **UnOp** – The type of *unary_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

- **init** – The initial value for the generalized sum.
- **binary_op** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init*.
- **unary_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_exclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *transform_exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::uninitialized_fill

Defined in header hpx/algorithm.hpp[656].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_fill_n*

template<typename **FwdIter**, typename **T**>

void *hpx*::**uninitialized_fill**(*FwdIter* first, *FwdIter* last, *T* const &value)

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *uninitialized_fill* algorithm returns nothing

[656] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> `hpx::uninitialized_fill`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &value)

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel *uninitialized_fill* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The initializations in the parallel *uninitialized_fill* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *uninitialized_fill* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns nothing otherwise.

hpx::uninitialized_fill_n

Defined in header hpx/algorithm.hpp[657].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_fill*

template<typename **FwdIter**, typename **Size**, typename **T**>

FwdIter `hpx::uninitialized_fill_n`(*FwdIter* first, *Size* count, *T* const &value)

Copies the given *value* value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *uninitialized_fill_n* algorithm returns a returns *FwdIter*. The *uninitialized_fill_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**, typename **T**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::uninitialized_fill_n`(*ExPolicy* &&policy, *FwdIter* first, *Size* count, *T* const &value)

[657] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Copies the given *value* value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel *uninitialized_fill_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The initializations in the parallel *uninitialized_fill_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *uninitialized_fill_n* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns FwdIter otherwise. The *uninitialized_fill_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

hpx::move

Defined in header hpx/algorithm.hpp[658].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> **hpx::move**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Moves the elements in the range [first, last), to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move. Executed according to the policy.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* move assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the move assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *move* algorithm returns a *hpx::future<FwdIter2>>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise.

[658] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The *move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

template<typename **FwdIter1**, typename **FwdIter2**>

FwdIter2 **hpx::move**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Moves the elements in the range [first, last), to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

> **Note**
>
> Complexity: Performs exactly *last - first* move assignments.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *move* algorithm returns a *FwdIter2*. The *move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

hpx::destroy

Defined in header hpx/algorithm.hpp[659].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::destroy_n*

template<typename **ExPolicy**, typename **FwdIter**>

util::detail::algorithm_result_t<*ExPolicy*> **hpx::destroy**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last). Executed according to the policy.

[659] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* operations.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *destroy* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

template<typename **`FwdIter`**>

void *`hpx::`***`destroy`**(*FwdIter* first, *FwdIter* last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).

> **Note**
>
> Complexity: Performs exactly *last* - *first* operations.

Template Parameters

`FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *destroy* algorithm returns a *void*

hpx::destroy_n

Defined in header hpx/algorithm.hpp[660].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::destroy*

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::destroy_n`(*ExPolicy* &&policy, *FwdIter* first, *Size* count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count). Executed according to the policy.

The operations in the parallel *destroy_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* operations, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

[660] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Returns

The *destroy_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *destroy_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename **FwdIter**, typename **Size**>

FwdIter `hpx::destroy_n`(*FwdIter* first, *Size* count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count).

> **Note**
>
> Complexity: Performs exactly *count* operations, if count > 0, no assignments otherwise.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *destroy_n* algorithm returns a *FwdIter* . The *destroy_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

hpx::experimental::reduction_min

Defined in header hpx/algorithm.hpp[661].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *hpx*::*parallel*::detail::min_of<*T*>> `hpx::experimental::reduction_min`(*T* &var)

The function template *reduction_min* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::min_of{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

[661] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

A parallel algorithm uses the *reduction_min* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::min_of{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *hpx*::*parallel*::detail::min_of<*T*>> `hpx::experimental::`**`reduction_min`**(*T* &var, *T* const &identity)

hpx::rotate

Defined in header hpx/algorithm.hpp[662].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::rotate_copy*

template<typename **FwdIter**>

FwdIter `hpx::rotate`(*FwdIter* first, *FwdIter* new_first, *FwdIter* last)

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel *rotate* algorithm execute in sequential order in the calling thread.

Note

Complexity: Linear in the distance between *first* and *last*.

Note

The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

Template Parameters

FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *rotate* algorithm returns a FwdIter. The *rotate* algorithm returns the iterator to the new location of the element pointed by first,equal to first + (last - new_first).

template<typename **ExPolicy**, typename **FwdIter**>

[662] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::rotate`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* new_first, *FwdIter* last)

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element. Executed according to the policy.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*.

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *rotate* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *rotate* algorithm returns the iterator equal to first + (last - new_first).

hpx::rotate_copy

Defined in header hpx/algorithm.hpp[663].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::rotate*

template<typename **FwdIter**, typename **OutIter**>

OutIter `hpx::rotate_copy`(*FwdIter* first, *FwdIter* new_first, *FwdIter* last, *OutIter* dest_first)

Copies the elements from the range [first, last), to another range beginning at *dest_first* in such a way, that the element *new_first* becomes the first element of the new range and *new_first* - 1 becomes the last element.

The assignments in the parallel *rotate_copy* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **OutIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a output iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_first** – Refers to the begin of the destination range.

Returns

The *rotate_copy* algorithm returns a output iterator, The *rotate_copy* algorithm returns the output iterator to the element past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

[663] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::rotate_copy`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* new_first, *FwdIter1* last, *FwdIter2* dest_first)

Copies the elements from the range [first, last), to another range beginning at *dest_first* in such a way, that the element *new_first* becomes the first element of the new range and *new_first* - 1 becomes the last element. Executed according to the policy.

The assignments in the parallel *rotate_copy* algorithm execute in sequential order in the calling thread.

The assignments in the parallel *rotate_copy* algorithm execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_first** – Refers to the begin of the destination range.

Returns

The *rotate_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel_task_policy* and returns FwdIter2 otherwise. The *rotate_copy* algorithm returns the output iterator to the element past the last element copied.

hpx::uninitialized_move

Defined in header hpx/algorithm.hpp[664].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_move_n*

template<typename **InIter**, typename **FwdIter**>

FwdIter hpx::**uninitialized_move**(*InIter* first, *InIter* last, *FwdIter* dest)

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move* algorithm returns *FwdIter*. The *uninitialized_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> hpx::**uninitialized_move**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state. Executed according to the policy.

[664] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *uninitialized_move* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_move* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move* algorithm returns a *hpx::future<FwdIter2>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *uninitialized_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

hpx::uninitialized_move_n

Defined in header hpx/algorithm.hpp[665].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_move*

template<typename **`InIter`**, typename **`Size`**, typename **`FwdIter`**>

[665] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

std::pair<*InIter*, *FwdIter*> hpx::**uninitialized_move_n**(*InIter* first, *Size* count, *FwdIter* dest)

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state.

> **Note**
>
> Complexity: Performs exactly *count* movements, if count > 0, no move operations otherwise.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move_n* algorithm returns a returns *std::pair<InIter,FwdIter>*. The *uninitialized_move_n* algorithm returns A pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

template<typename **ExPolicy**, typename **FwdIter1**, typename **Size**, typename **FwdIter2**>

parallel::*util*::detail::algorithm_result<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>>::type hpx::**uninitialized_move_n**(*ExPolicy* &&policy, *FwdIter1* first, *Size* count, *FwdIter2* dest)

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state. Executed according to the policy.

The assignments in the parallel *uninitialized_move_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_move_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* movements, if count > 0, no move operations otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move_n* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. The *uninitialized_move_n* algorithm returns A pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

hpx::fill

Defined in header hpx/algorithm.hpp[666].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::fill_n*

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>

util::detail::algorithm_result_t<*ExPolicy*> **hpx::fill**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* value)

Assigns the given value to the elements in the range [first, last). Executed according to the policy.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last - first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *fill* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *void*.

[666] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

template<typename **FwdIter**, typename **T**>

void *hpx*::**fill**(*FwdIter* first, *FwdIter* last, *T* value)

Assigns the given value to the elements in the range [first, last).

> **Note**
>
> Complexity: Performs exactly *last - first* assignments.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *fill* algorithm returns a *void*.

hpx::fill_n

Defined in header hpx/algorithm.hpp[667].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::fill*

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**, typename **T**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> *hpx*::**fill_n**(*ExPolicy* &&policy, *FwdIter* first, *Size* count, *T* value)

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise. Executed according to the policy.

The comparisons in the parallel *fill_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

[667] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

> **Note**
>
> Complexity: Performs exactly *count* assignments, for count > 0.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *fill_n* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *void*.

template<typename **FwdIter**, typename **Size**, typename **T**>

FwdIter hpx::**fill_n**(*FwdIter* first, *Size* count, *T* value)

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

> **Note**
>
> Complexity: Performs exactly *count* assignments, for count > 0.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *fill_n* algorithm returns a *FwdIter*.

hpx::count

Defined in header hpx/algorithm.hpp[668].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::count_if*

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>

util::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::difference_type>::type *hpx*::**count**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &value)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*. Executed according to the policy.

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

Note

Complexity: Performs exactly *last* - *first* comparisons.

Note

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

[668] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to search for (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

Returns

The *count* algorithm returns a *hpx::future<difference_type>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *std::iterator_traits<FwdIterB>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

template<typename **InIter**, typename **T**>

std::iterator_traits<*InIter*>::difference_type `hpx::count`(*InIter* first, *InIter* last, *T* const &value)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*.

> **Note**
>
> Complexity: Performs exactly *last* - *first* comparisons.

Template Parameters

- **InIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

Returns

The *count* algorithm returns a *difference_type* (where *difference_type* is defined by *std::iterator_traits<InIter>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

hpx::count_if

Defined in header hpx/algorithm.hpp[669].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::count*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>

util::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::difference_type>::type **hpx::count_if**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true. Executed according to the policy.

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

> **Note**
>
> The assignments in the parallel *count_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

> **Note**
>
> The assignments in the parallel *count_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Template Parameters

[669] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *count_if* algorithm returns *hpx::future<difference_type>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *std::iterator_traits<FwdIter>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

template<typename **InIter**, typename **F**>

std::iterator_traits<*InIter*>::difference_type **hpx::count_if**(*InIter* first, *InIter* last, *F* &&f)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **InIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

The *count_if* algorithm returns *difference_type* (where a difference_type is defined by *std::iterator_traits<InIter>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

hpx::experimental::for_each_index

Defined in header hpx/algorithm.hpp[670].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Mapping**, typename **Fun**>

constexpr void `hpx::experimental::for_each_index`(*Mapping* const &mapping, *Fun* fun)

Calls *fun* with every multidimensional index in the domain of *mapping* (i.e., its extents), in sequential order.

If *fun* returns a result, the result is ignored.

The layout mapping is a hint; implementations are encouraged to choose an iteration order that performs well for the given mapping.

> **Note**
>
> Complexity: Applies *fun* exactly the product of all extents of *mapping* times.

Template Parameters

- **Mapping** – A type meeting the layout mapping requirements. Must expose *index_type*, *extents_type*, `static` *rank()*, and *extents()*.
- **Fun** – The type of the function/function object to use (deduced). *Fun* must meet *Copy-Constructible* and be invocable with exactly *Mapping::rank()* arguments of type *Mapping::index_type*.

[670] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **mapping** – The layout mapping whose extents define the iteration domain.
- **fun** – Callable invoked as `fun(i0, i1, ...)` for every multidimensional index in the domain.

template<typename **ExPolicy**, typename **Mapping**, typename **Fun**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> *hpx*::*experimental*::**for_each_index**(*ExPolicy* &&policy, *Mapping* const &mapping, *Fun* fun)

Calls *fun* with every multidimensional index in the domain of *mapping* (i.e., its extents), executed according to *policy*.

If *fun* returns a result, the result is ignored.

> **Note**
>
> Complexity: Applies *fun* exactly the product of all extents of *mapping* times.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced).
- **Mapping** – A type meeting the layout mapping requirements. Must meet *CopyConstructible*.
- **Fun** – The type of the function/function object to use (deduced). Must meet *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for scheduling.
- **mapping** – The layout mapping whose extents define the iteration domain.
- **fun** – Callable invoked as `fun(i0, i1, ...)` for every multidimensional index in the domain.

Returns

hpx::future<void> if the execution policy is *sequenced_task_policy* or *parallel_task_policy*, *void* otherwise.

hpx::reduce

Defined in header hpx/algorithm.hpp[671].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter**, typename **F**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> **hpx::reduce**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init, *F* &&f)

Returns GENERALIZED_SUM(f, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *f*.

> **Note**
>
> GENERALIZED_SUM(op, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

[671] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
util::detail::algorithm_result_t<*ExPolicy*, *T*> **hpx::reduce**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the operator+().

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter**>

hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::value_type>::type **hpx::reduce**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last)

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the operator+().

> **Note**
>
> The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

> **Note**
>
> GENERALIZED_SUM(+, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns T otherwise (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **FwdIter**, typename **F**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>

T `hpx::`**`reduce`**(*FwdIter* first, *FwdIter* last, *T* init, *F* &&f)

Returns GENERALIZED_SUM(f, init, *first, . . . , *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicate *f*.

Note

GENERALIZED_SUM(op, a1, . . . , aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, . . . , bK), GENERALIZED_SUM(op, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns *T*. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>

T `hpx::reduce`(*FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the operator+().

> **Note**
>
> GENERALIZED_SUM(+, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *T*. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **FwdIter**>

std::iterator_traits<*FwdIter*>::value_type *hpx*::**reduce**(*FwdIter* first, *FwdIter* last)

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the operator+().

> **Note**
>
> The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

> **Note**
>
> GENERALIZED_SUM(+, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and
>   - 1 < K+1 = M <= N.

Template Parameters

FwdIter – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns *T* (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

hpx::find

Defined in header hpx/algorithm.hpp[672].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_if*
- *hpx::find_if_not*
- *hpx::find_end*
- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::find`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &val)

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most last - first applications of the operator==().

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to find (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

[672] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **val** – the value to compare the elements to

Returns

The *find* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

template<typename **InIter**, typename **T**>

InIter `hpx::`**find**(*InIter* first, *InIter* last, *T* const &val)

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

> **Note**
>
> Complexity: At most last - first applications of the operator==().

Template Parameters

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to find (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to

Returns

The *find* algorithm returns a *InIter*. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

hpx::find_if

Defined in header hpx/algorithm.hpp[673].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if_not*
- *hpx::find_end*

[673] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::find_if`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns true. Executed according to the policy.

The comparison operations in the parallel *find_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most last - first applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise.

The *find_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate f, the algorithm returns *last*.

template<typename **InIter**, typename **F**>

InIter `hpx::`**`find_if`**(*InIter* first, *InIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns true.

> **Note**
>
> Complexity: At most last - first applications of the predicate.

Template Parameters

- **`InIter`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`f`** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if* algorithm returns a *InIter*. The *find_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate f, the algorithm returns *last*.

hpx::find_if_not

Defined in header hpx/algorithm.hpp[674].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if*
- *hpx::find_end*
- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> hpx::**find_if_not**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns false. Executed according to the policy.

The comparison operations in the parallel *find_if_not* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_if_not* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most last - first applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

[674] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if_not* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find_if_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate f, the algorithm returns *last*.

template<typename **FwdIter**, typename **F**>

FwdIter hpx::**find_if_not**(*FwdIter* first, *FwdIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns false.

> **Note**
>
> Complexity: At most last - first applications of the predicate.

Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if_not* algorithm returns a *FwdIter*. The *find_if_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate f, the algorithm returns *last*.

hpx::find_end

Defined in header hpx/algorithm.hpp[675].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if*
- *hpx::find_if_not*
- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> hpx::**find_end**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate *op* to compare elements. Executed according to the policy.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find_end* is available if the user decides to provide the algorithm their own predicate *op*.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

[675] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_end* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> hpx::**find_end**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the last subsequence of elements [first2, last2) found in the range [first, last). Elements are compared using *operator*==. Executed according to the policy.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in

an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`last2`** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_end* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`** = detail::equal_to>

FwdIter1 `hpx::`**`find_end`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate *op* to compare elements.

This overload of *find_end* is available if the user decides to provide the algorithm their own predicate *op*.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_end* algorithm returns a *FwdIter1*. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

template<typename **FwdIter1**, typename **FwdIter2**>

FwdIter1 hpx::**find_end**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the last subsequence of elements [first2, last2) found in the range [first, last). Elements are compared using *operator==*.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_end* algorithm returns a *FwdIter1*. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

hpx::find_first_of

Defined in header hpx/algorithm.hpp[676].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if*
- *hpx::find_if_not*
- *hpx::find_end*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> hpx::**find_first_of**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

[676] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses binary predicate *op* to compare elements. Executed according to the policy.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find_first_of* is available if the user decides to provide the algorithm their own predicate *op*.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_first_of* algorithm returns a *hpx::future<FwdIter1>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter1* otherwise. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>

util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> `hpx::`**`find_first_of`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last)

Searches the range [first, last) for any elements in the range [s_first, s_last). Elements are compared using *operator*==. Executed according to the policy.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_first_of* algorithm returns a *hpx::future<FwdIter1>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter1* otherwise. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>

FwdIter1 hpx::**find_first_of**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses binary predicate *op* to compare elements.

This overload of *find_first_of* is available if the user decides to provide the algorithm their own predicate *op*.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_first_of* algorithm returns a *FwdIter1*. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

template<typename **FwdIter1**, typename **FwdIter2**>

FwdIter1 hpx::**find_first_of**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last)

Searches the range [first, last) for any elements in the range [s_first, s_last). Elements are compared using *operator==*.

> **Note**
>
> Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_first_of* algorithm returns a *FwdIter1*. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

hpx::uninitialized_relocate

Defined in header hpx/algorithm.hpp[677].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_relocate_n*

template<typename **InIter1**, typename **InIter2**, typename **FwdIter**>

FwdIter hpx::**uninitialized_relocate**(*InIter1* first, *InIter2* last, *FwdIter* dest)

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: time: O(n), space: O(1) 1) For "trivially relocatable" underlying types (T) and a contiguous iterator range [first, last): std::distance(first, last)*sizeof(T) bytes are copied. 2) For "trivially relocatable" underlying types (T) and a non-contiguous iterator range [first, last): std::distance(first, last) memory copies of sizeof(T) bytes each are performed. 3) For "non-trivially relocatable" underlying types (T): std::distance(first, last) move assignments and destructions are performed.

> **Note**
>
> Declare a type as "trivially relocatable" using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

Template Parameters

677 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **InIter1** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the source iterator last (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_relocate* algorithm returns *FwdIter*. The *uninitialized_relocate* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

template<typename **ExPolicy**, typename **InIter1**, typename **InIter2**, typename **FwdIter**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> hpx::**uninitialized_relocate**(*ExPolicy* &&policy, *InIter1* first, *InIter2* last, *FwdIter* dest)

Relocates the elements in the range defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: time: O(n), space: O(1) 1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, last): std::distance(first, last)*sizeof(T) bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, last): std::distance(first, last) memory copies of sizeof(T) bytes each are performed. 3) For “non-trivially relocatable” underlying types (T): std::distance(first, last) move assignments and destructions are performed.

Note

Declare a type as "trivially relocatable" using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

Note

Parallel execution requires both *first* and *dest* to be contiguous iterators. If either iterator is non-contiguous, the algorithm cannot determine whether the source and destination ranges overlap, and will silently fall back to sequential execution regardless of the execution policy provided.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **InIter1** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the source iterator last (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range. The assignments in the parallel *uninitialized_relocate_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

Returns

The *uninitialized_relocate* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_relocate* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

hpx::uninitialized_relocate_n

Defined in header hpx/algorithm.hpp[678].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_relocate*

template<typename **InIter**, typename **Size**, typename **FwdIter**>

FwdIter `hpx::`**`uninitialized_relocate_n`**(*InIter* first, *Size* count, *FwdIter* dest)

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate_n* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

Note

Complexity: time: O(n), space: O(1) 1) For "trivially relocatable" underlying types (T) and a contiguous iterator range [first, first+count): `count*sizeof(T)` bytes are copied. 2) For "trivially relocatable" underlying types (T) and a non-contiguous iterator range [first, first+count): `count` memory copies of sizeof(T) bytes each are performed. 3) For "non-trivially relocatable" underlying types (T): `count` move assignments and destructions are performed.

Note

Declare a type as "trivially relocatable" using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

Template Parameters

- **`InIter`** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **`Size`** – The type of the argument specifying the number of elements to relocate.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

[678] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `count` – Refers to the number of elements starting at *first* the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.

Returns

The *uninitialized_relocate_n* algorithm returns *FwdIter*. The *uninitialized_relocate_n* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

template<typename **ExPolicy**, typename **InIter**, typename **Size**, typename **FwdIter**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> *hpx*::**uninitialized_relocate_n**(*ExPolicy* &&policy, *InIter* first, *Size* count, *FwdIter* dest)

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_relocate_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: time: O(n), space: O(1) 1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, first+count): `count*sizeof(T)` bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, first+count): `count` memory copies of sizeof(T) bytes each are performed. 3) For “non-trivially relocatable” underlying types (T): `count` move assignments and destructions are performed.

> **Note**
>
> Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

Note

Parallel execution requires both *first* and *dest* to be contiguous iterators. If either iterator is non-contiguous, the algorithm cannot determine whether the source and destination ranges overlap, and will silently fall back to sequential execution regardless of the execution policy provided.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **InIter** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to relocate.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_relocate_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_relocate_n* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

hpx::remove_copy

Defined in header hpx/algorithm.hpp[679].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::remove_copy_if*

template<typename **InIter**, typename **OutIter**, typename **T** = typename *std*::iterator_traits<*InIter*>::value_type>

OutIter `hpx::`**`remove_copy`**(*InIter* first, *InIter* last, *OutIter* dest, *T* const &value)

Copies the elements in the range, defined by [first, last), to another range beginning at

[679] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

dest. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: *it == value

The assignments in the parallel *remove_copy* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*, here comparison operator.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type that the result of dereferencing FwdIter1 is compared to.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **value** – Value to be removed.

Returns

The *remove_copy* algorithm returns an *OutIter*. The *remove_copy* algorithm returns the iterator to the element past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **T** = typename *std*::iterator_traits<InIter>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> hpx::**remove_copy**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* const &value)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved. Executed according to the policy.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: *it == value

The assignments in the parallel *remove_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*, here comparison operator.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type that the result of dereferencing FwdIter1 is compared to.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **value** – Value to be removed.

Returns

The *remove_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *remove_copy* algorithm returns the iterator to the element past the last element copied.

hpx::remove_copy_if

Defined in header hpx/algorithm.hpp[680].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

- *hpx::remove_copy*

[680] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

template<typename **InIter**, typename **OutIter**, typename **Pred**>

OutIter hpx::**remove_copy_if**(*InIter* first, *InIter* last, *OutIter* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *pred* returns false. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: INVOKE(pred, *it) != false.

The assignments in the parallel *remove_copy_if* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_copy_if* algorithm returns an *OutIter* The *remove_copy_if* algorithm returns the iterator to the element past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::remove_copy_if`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *pred* returns false. The order of the elements that are not removed is preserved. Executed according to the policy.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: INVOKE(pred, *it) != false.

The assignments in the parallel *remove_copy_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove_copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_copy_if* requires *Pred* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns

true for the elements to be removed. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_copy_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *remove_copy_if* algorithm returns the iterator to the element past the last element copied.

hpx::set_difference

Defined in header hpx/algorithm.hpp[681].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter3*> `hpx::set_difference`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

Equivalent elements are treated individually, that is, if some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly std::max(m-n, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (for *sequenced_task_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

[681] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_difference* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter3* otherwise. The *set_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>

FwdIter3 **hpx::set_difference**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

Equivalent elements are treated individually, that is, if some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly std::max(m-n, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_difference* algorithm returns a *FwdIter3*. The *set_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::reduce_by_key

Defined in header hpx/algorithm.hpp[682].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

> **Warning**
>
> doxygenfunction: Cannot find function "hpx::reduce_by_key" in doxygen xml output for project "hpx" from directory: ../hpx_autodoc

hpx::nth_element

Defined in header hpx/algorithm.hpp[683].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandomIt**, typename **Pred** = *hpx*::*parallel*::detail::less>

void *hpx*::**nth_element**(*RandomIt* first, *RandomIt* nth, *RandomIt* last, *Pred* &&pred = *Pred*())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element. Executed according to the policy.

The comparison operations in the parallel *nth_element* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters

- **RandomIt** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

[682] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp
[683] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to std::less<>.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

Returns

The *nth_element* algorithms returns nothing.

template<typename **ExPolicy**, typename **RandomIt**, typename **Pred** = *hpx*::*parallel*::detail::less>

void *hpx*::**nth_element**(*ExPolicy* &&policy, *RandomIt* first, *RandomIt* nth, *RandomIt* last, *Pred* &&pred = *Pred*())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel *nth_element* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *nth_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **RandomIt** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to std::less<>.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

Returns

The *nth_element* algorithms returns nothing.

hpx::remove

Defined in header hpx/algorithm.hpp[684].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::remove_if*

template<typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>

FwdIter hpx::**remove**(*FwdIter* first, *FwdIter* last, *T* const &value)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*.

The assignments in the parallel *remove* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the operator==().

[684] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.

Returns

The *remove* algorithm returns a *FwdIter*. The *remove* algorithm returns the iterator to the new end of the range.

template<typename **ExPolicy**, typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **hpx::remove**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &value)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*. Executed according to the policy.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the operator==().

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.

Returns

The *remove* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *remove* algorithm returns the iterator to the new end of the range.

hpx::remove_if

Defined in header hpx/algorithm.hpp[685].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::remove*

template<typename **FwdIter**, typename **Pred**>

FwdIter `hpx::remove_if`(*FwdIter* first, *FwdIter* last, *Pred* &&pred)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true.

The assignments in the parallel *remove_if* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_if* requires *Pred* to meet the requirements of *CopyConstructible*.

Parameters

[685] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_if* algorithm returns a *FwdIter*. The *remove_if* algorithm returns the iterator to the new end of the range.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::remove_if`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true. Executed according to the policy.

The assignments in the parallel *remove_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_if* requires *Pred* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *remove_if* algorithm returns the iterator to the new end of the range.

hpx::reverse

Defined in header hpx/algorithm.hpp[686].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::reverse_copy*

template<typename **BidirIter**>

void *hpx*::**reverse**(*BidirIter* first, *BidirIter* last)

Reverses the order of the elements in the range [first, last). Behaves as if applying *std::iter_swap* to every pair of iterators first+i, (*last-i*) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*.

Template Parameters

BidirIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

[686] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reverse* algorithm returns *void*.

template<typename **ExPolicy**, typename **BidirIter**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, void> `hpx::reverse`(*ExPolicy* &&policy, *BidirIter* first, *BidirIter* last)

Reverses the order of the elements in the range [first, last). Behaves as if applying *std::iter_swap* to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2. Executed according to the policy.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reverse* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::reverse_copy

Defined in header hpx/algorithm.hpp[687].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::reverse*

template<typename **BidirIter**, typename **OutIter**>

OutIter `hpx::reverse_copy`(*BidirIter* first, *BidirIter* last, *OutIter* dest)

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse_copy* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the begin of the destination range.

Returns

The *reverse_copy* algorithm returns an *OutIter*. The *reverse_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **BidirIter**, typename **FwdIter**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::reverse_copy`(*ExPolicy* &&policy, *BidirIter* first, *BidirIter* last, *FwdIter* dest)

[687] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined. Executed according to the policy.

The assignments in the parallel *reverse_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the begin of the destination range.

Returns

The *reverse_copy* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *reverse_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::experimental::sort_by_key

Defined in header hpx/algorithm.hpp[688].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **KeyIter**, typename **ValueIter**, typename **Compare** = detail::less>

util::detail::algorithm_result_t<*ExPolicy*, sort_by_key_result<*KeyIter*, *ValueIter*>> `hpx::experimental::sort_by_key`(*ExPolicy* &&policy, *KeyIter* key_first, *KeyIter* key_last, *ValueIter* value_first, *Compare* &&comp = *Compare*())

Sorts one range of data using keys supplied in another range. The key elements in the range [key_first, key_last) are sorted in ascending order with the corresponding elements in the value range moved to follow the sorted order. The algorithm is not stable, the order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, *(i + n), *i) == false.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it

[688] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

applies user-provided function objects.

- **KeyIter** – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **ValueIter** – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Compare** – The type of the function/function object to use (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **key_first** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key_last** – Refers to the end of the sequence of key elements the algorithm will be applied to.
- **value_first** – Refers to the beginning of the sequence of value elements the algorithm will be applied to, the range of elements must match [key_first, key_last)
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

Returns

The *sort_by_key* algorithm returns a hpx::future<*sort_by_key_result<KeyIter,ValueIter>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *otherwise*. The algorithm returns a pair holding an iterator pointing to the first element after the last element in the input key sequence and an iterator pointing to the first element after the last element in the input value sequence.

hpx::replace

Defined in header hpx/algorithm.hpp[689].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::replace_if*
- *hpx::replace_copy*
- *hpx::replace_copy_if*

template<typename **InIter**, typename **T** = typename *std*::iterator_traits<*InIter*>::value_type>

void *hpx*::**replace**(*InIter* first, *InIter* last, *T* const &old_value, *T* const &new_value)

Replaces all elements satisfying specific criteria with *new_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: *it == old_value

[689] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the old and new values to replace (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace* algorithm returns a *void*.

template<typename **ExPolicy**, typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, void> *hpx*::**replace**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &old_value, *T* const &new_value)

Replaces all elements satisfying specific criteria with *new_value* in the range [first, last). Executed according to the policy.

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: *it == old_value

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the old and new values to replace (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::replace_if

Defined in header hpx/algorithm.hpp[690].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::replace*
- *hpx::replace_copy*
- *hpx::replace_copy_if*

template<typename **Iter**, typename **Pred**, typename **T** = typename *std*::iterator_traits<*Iter*>::value_type>

void `hpx::replace_if`(*Iter* first, *Iter* last, *Pred* &&pred, *T* const &new_value)

Replaces all elements satisfying specific criteria (for which predicate *pred* returns true) with *new_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel *replace_if* algorithm execute in sequential order in the calling thread.

[690] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace_if* algorithm returns *void*.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, void> hpx::**replace_if**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred, *T* const &new_value)

Replaces all elements satisfying specific criteria (for which predicate *f* returns true) with *new_value* in the range [first, last). Executed according to the policy.

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel *replace_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an

unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace_if* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::replace_copy

Defined in header hpx/algorithm.hpp[691].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::replace*
- *hpx::replace_if*
- *hpx::replace_copy_if*

template<typename **InIter**, typename **OutIter**, typename **T** = typename *std*::iterator_traits<*OutIter*>::value_type>

OutIter `hpx::replace_copy`(*InIter* first, *InIter* last, *OutIter* dest, *T* const &old_value, *T* const &new_value)

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value

The assignments in the parallel *replace_copy* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the old and new values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.

[691] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

Returns

The *replace_copy* algorithm returns an *OutIter* The *replace_copy* algorithm returns the Iterator to the element past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **T** = typename *std*::iterator_traits<*FwdIter2*>::value_type>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::replace_copy`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* const &old_value, *T* const &new_value)

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new_value*. Executed according to the policy.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value

The assignments in the parallel *replace_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last - first* applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the old and new values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *replace_copy* algorithm returns the Iterator to the element past the last element copied.

hpx::replace_copy_if

Defined in header hpx/algorithm.hpp[692].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::replace*
- *hpx::replace_if*

template<typename **InIter**, typename **OutIter**, typename **Pred**, typename **T** = typename *std*::iterator_traits<*OutIter*>::value_type>

OutIter hpx::**replace_copy_if**(*InIter* first, *InIter* last, *OutIter* dest, *Pred* &&pred, *T* const &new_value)

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, *(first + (i - result))) != false

The assignments in the parallel *replace_copy_if* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last - first* applications of the predicate.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

692 http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace_copy_if* algorithm returns an *OutIter*. The *replace_copy_if* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred**, typename **T** = typename *std*::iterator_traits<*FwdIter2*>::value_type>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> hpx::**replace_copy_if**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred, *T* const &new_value)

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, *(first + (i - result))) != false

The assignments in the parallel *replace_copy_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace_copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *replace_copy_if* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace_copy_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *replace_copy_if* algorithm returns the iterator to the element in the destination range, one past the last element copied.

hpx::sort

Defined in header hpx/algorithm.hpp[693].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandomIt**, typename **Comp** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::identity>

void *hpx*::**sort**(*RandomIt* first, *RandomIt* last, *Comp* &&comp, *Proj* &&proj = *Proj*())

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The assignments in the parallel *sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *sort* algorithm returns *void*.

[693] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

template<typename **ExPolicy**, typename **RandomIt**, typename **Comp** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::identity>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **hpx::sort**(*ExPolicy* &&policy, *RandomIt* first, *RandomIt* last, *Comp* &&comp, *Proj* &&proj)

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *sort* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::partition

Defined in header hpx/algorithm.hpp[694].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::stable_partition*
- *hpx::partition_copy*

template<typename **FwdIter**, typename **Pred**, typename **Proj** = *hpx*::identity>

FwdIter **hpx::partition**(*FwdIter* first, *FwdIter* last, *Pred* &&pred, *Proj* &&proj = *Proj*())

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: At most 2 * (last - first) swaps. Exactly *last* - *first* applications of the predicate and projection.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

[694] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

Returns

The *partition* algorithm returns returns *FwdIter*. The *partition* algorithm returns the iterator to the first element of the second group.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**, typename **Proj** = *hpx*::identity>

parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> hpx::**partition**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred, *Proj* &&proj = *Proj*())

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2 * (last - first) swaps. Exactly *last* - *first* applications of the predicate and projection.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

Returns

The *partition* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *parallel_task_policy* and returns *FwdIter* otherwise. The *partition* algorithm returns the iterator to the first element of the second group.

hpx::stable_partition

Defined in header hpx/algorithm.hpp[695].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::partition*
- *hpx::partition_copy*

template<typename **BidirIter**, typename **F**, typename **Proj** = *hpx*::identity>

BidirIter hpx::**stable_partition**(*BidirIter* first, *BidirIter* last, *F* &&f, *Proj* &&proj = *Proj*())

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) INVOKE(f, INVOKE (proj, *j)) != false, and for every iterator k in the range [i, last), INVOKE(f, INVOKE (proj, *k)) == false

The invocations of *f* in the parallel *stable_partition* algorithm invoked without an execution policy object executes in sequential order in the calling thread.

> **Note**
>
> Complexity: At most (last - first) * log(last - first) swaps, but only linear number of swaps if there is enough extra memory. Exactly *last* - *first* applications of the predicate and projection.

Template Parameters

[695] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool fun(const Type &a);
  ```

  The signature does not need to have const&. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

Returns

The *stable_partition* algorithm returns an iterator i such that for every iterator j in the range [first, i), f(*j) != false INVOKE(f, INVOKE(proj, *j)) != false, and for every iterator k in the range [i, last), f(*k) == false INVOKE(f, INVOKE (proj, *k)) == false. The relative order of the elements in both groups is preserved.

template<typename **ExPolicy**, typename **BidirIter**, typename **F**, typename **Proj** = *hpx*::identity>

parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *BidirIter*> **hpx::stable_partition**(*ExPolicy* &&policy, *BidirIter* first, *BidirIter* last, *F* &&f, *Proj* &&proj = *Proj*())

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) INVOKE(f, INVOKE (proj, *j)) != false, and for every iterator k in the range [i, last), INVOKE(f, INVOKE (proj, *k)) == false

The invocations of *f* in the parallel *stable_partition* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The invocations of *f* in the parallel *stable_partition* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most (last - first) * log(last - first) swaps, but only linear number of swaps if there is enough extra memory. Exactly *last* - *first* applications of the predicate and projection.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool fun(const Type &a);
  ```

  The signature does not need to have const&. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

Returns

The *stable_partition* algorithm returns an iterator i such that for every iterator j in the range [first, i), f(*j) != false INVOKE(f, INVOKE(proj, *j)) != false, and for every iterator k in the range [i, last), f(*k) == false INVOKE(f, INVOKE (proj, *k)) == false. The relative order of the elements in both groups is preserved. If the execution policy is of type *parallel_task_policy* the algorithm returns a *future*<> referring to this iterator.

hpx::partition_copy

Defined in header hpx/algorithm.hpp[696].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::partition*
- *hpx::stable_partition*

template<typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred**, typename **Proj** = *hpx*::identity>

std::pair<*FwdIter2*, *FwdIter3*> **hpx::partition_copy**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest_true, *FwdIter3* dest_false, *Pred* &&pred, *Proj* &&proj = *Proj*())

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred* are copied to the range beginning at *dest_true*. The rest of the elements are copied to the range beginning at *dest_false*. The order of the elements is preserved.

The assignments in the parallel *partition_copy* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

[696] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

Returns

The *partition_copy* algorithm returns *std::pair<OutIter1, OutIter2>*. The *partition_copy* algorithm returns the pair of the destination iterator to the end of the *dest_true* range, and the destination iterator to the end of the *dest_false* range.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred**, typename **Proj** = *hpx*::identity>

parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter2*, *FwdIter3*>> `hpx::partition_copy`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest_true, *FwdIter3* dest_false, *Pred* &&pred, *Proj* &&proj = *Proj*())

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred*, are copied to the range beginning at *dest_true*. The rest of the elements are copied to the range beginning at *dest_false*. The order of the elements is preserved.

The assignments in the parallel *partition_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an

unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

Returns

The *partition_copy* algorithm returns a hpx::future<*std::pair<OutIter1, OutIter2*>> if the execution policy is of type *parallel_task_policy* and returns *std::pair<OutIter1, OutIter2*> otherwise. The *partition_copy* algorithm returns the pair of the destination iterator to the end of the *dest_true* range, and the destination iterator to the end of the *dest_false* range.

hpx::transform_reduce

Defined in header hpx/algorithm.hpp[697].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter**, typename **T**, typename **Reduce**, typename **Convert**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::transform_reduce`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))). Executed according to the policy.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

> **Note**
>
> GENERALIZED_SUM(op, a1, …, aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
>   - b1, …, bN may be any permutation of a1, …, aN and

[697] http://github.com/TheHPXProject/hpx/blob/19fe7fe3cad79cf1ed28b4a7ede713343209d8d7/libs/full/include/include/hpx/algorithm.hpp

- 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.
- **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel_task_policy* and returns *T* otherwise. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **InIter**, typename **T**, typename **Reduce**, typename **Convert**>

T *hpx*::**transform_reduce**(*InIter* first, *InIter* last, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), ..., conv_op(*(first + (last - first) - 1))).

The difference between *transform_reduce* and *accumulate* is that the behavior of *transform_reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

> **Note**
>
> GENERALIZED_SUM(op, a1, ..., aN) is defined as follows:
>
> - a1 when N is 1
> - op(GENERALIZED_SUM(op, b1, ..., bK), GENERALIZED_SUM(op, bM, ..., bN)), where:
>   - b1, ..., bN may be any permutation of a1, ..., aN and
>   - 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.

- **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns a *T*. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **T**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> **hpx::transform_reduce**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *T* init)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2. Executed according to the policy.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as return) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise.

template<typename **InIter1**, typename **InIter2**, typename **T**>

T hpx::**transform_reduce**(*InIter1* first1, *InIter1* last1, *InIter2* first2, *T* init)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

> **Note**
>
> Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **InIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as return) values (deduced).

Parameters

- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

Returns

The *transform_reduce* algorithm returns a *T*.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **T**, typename **Reduce**, typename **Convert**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::transform_reduce`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2. Executed according to the policy.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

- **red_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **conv_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *red_op*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise.

template<typename **InIter1**, typename **InIter2**, typename **T**, typename **Reduce**, typename **Convert**>

T *hpx*::**transform_reduce**(ExPolicy &&policy, *InIter1* first1, *InIter1* last1, *InIter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

> **Note**
>
> Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **InIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.

- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.
- **red_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.
- **conv_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *red_op*.

Returns

The *transform_reduce* algorithm returns a *T*.

template<typename **ExPolicy**, typename **Iter**, typename **Sent**, typename **T**, typename **Reduce**, typename **Convert**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`transform_reduce`**(*ExPolicy* &&policy, *Iter* first, *Sent* last, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters
