**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *red\_op* and *conv\_op*.

---

---

**Note:** GENERALIZED\_SUM(op, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(op, b1, ..., bK), GENERALIZED\_SUM(op, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv\_op* can be implicitly converted to any of those types.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

#### Returns

The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel\_task\_policy* and returns *T* otherwise. The *transform\_reduce* algorithm returns the result of the generalized sum over the values returned from *conv\_op* when applied to the elements given by the input range [first, last).

```
template<typename Rng, typename T, typename Reduce, typename Convert>
T transform_reduce(Rng &&rng, T init, Reduce &&red_op, Convert &&conv_op)
```

Returns GENERALIZED\_SUM(red\_op, init, conv\_op(\*first), ..., conv\_op(\*(first + (last - first) - 1))).

The difference between *transform\_reduce* and *accumulate* is that the behavior of *transform\_reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *red\_op* and *conv\_op*.

---

---

**Note:** GENERALIZED\_SUM(op, a1, ..., aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED\_SUM(op, b1, ..., bK), GENERALIZED\_SUM(op, bM, ..., bN)), where:

- $b_1, \dots, b_N$  may be any permutation of  $a_1, \dots, a_N$  and
  - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv\_op* can be implicitly converted to any of those types.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

### Returns

The *transform\_reduce* algorithm returns *T*. The *transform\_reduce* algorithm returns the result of the generalized sum over the values returned from *conv\_op* when applied to the elements given by the input range [first, last).

```
template<typename ExPolicy, typename Rng, typename Iter2, typename T>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy &&policy, Rng
&&rng, Iter2 first2, T init)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op2*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

#### Returns

The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise.

```
template<typename Rng, typename Iter2, typename T>
T transform_reduce(Rng &&rng, Iter2 first2, T init)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op2*.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.

- **init** – The initial value for the sum.

#### Returns

The *transform\_reduce* algorithm returns *T*.

```
template<typename ExPolicy, typename Rng, typename Iter2, typename T, typename Reduce, typename Convert>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy &&policy, Rng
                                                                    &&rng, Iter2 first2, T init,
                                                                    Reduce &&red_op, Convert
                                                                    &&conv_op)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op2*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *op2*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *op1*.

### Returns

The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise.

```
template<typename Rng, typename Iter2, typename T, typename Reduce, typename Convert>
T transform_reduce(Rng &&rng, Iter2 first2, T init, Reduce &&red_op, Convert &&conv_op)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op2*.

---

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *op2*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *op1*.

#### Returns

The *transform\_reduce* algorithm returns *T*.

### hpx::ranges::reverse, hpx::ranges::reverse\_copy

Defined in header `hpx/algorithm.hpp`<sup>627</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **ranges**

#### Functions

```
template<typename Iter, typename Sent>  
Iter reverse(Iter first, Sent sent)
```

Reverses the order of the elements in the range `[first, last)`. Behaves as if applying `std::iter_swap` to every pair of iterators `first+i`, `(last-i) - 1` for each non-negative `i < (last-first)/2`.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.

#### Returns

The *reverse* algorithm returns a *Iter*. It returns *last*.

```
template<typename Rng>
```

---

<sup>627</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

`std::ranges::iterator_t<Rng> reverse(Rng &&rng)`

Uses *rng* as the source range, as if using `util::begin(rng)` as *first* and `ranges::end(rng)` as *last*. Reverses the order of the elements in the range [*first*, *last*). Behaves as if applying `std::iter_swap` to every pair of iterators *first*+*i*, (*last*-*i*) - 1 for each non-negative *i* < (*last*-*first*)/2.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

**Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

#### Parameters

**rng** – Refers to the sequence of elements the algorithm will be applied to.

#### Returns

The *reverse* algorithm returns a `hpx::traits::range_iterator<Rng>::type`. It returns *last*.

```
template<typename ExPolicy, typename Iter, typename Sent>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> reverse(ExPolicy &&policy, Iter first,
                                                                    Sent sent)
```

Reverses the order of the elements in the range [*first*, *last*). Behaves as if applying `std::iter_swap` to every pair of iterators *first*+*i*, (*last*-*i*) - 1 for each non-negative *i* < (*last*-*first*)/2.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.

#### Returns

The *reverse* algorithm returns a `hpx::future<Iter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *Iter* otherwise. It returns *last*.

```
template<typename ExPolicy, typename Rng>
```

*parallel::util::detail::algorithm\_result<ExPolicy, std::ranges::iterator\_t<Rng>>* **reverse**(*ExPolicy* &&policy, *Rng* &&rng)

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Reverses the order of the elements in the range  $[first, last)$ . Behaves as if applying `std::iter_swap` to every pair of iterators  $first+i$ ,  $(last-i) - 1$  for each non-negative  $i < (last-first)/2$ .

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

#### Returns

The *reverse* algorithm returns a *hpx::future<std::ranges::iterator\_t<Rng>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *hpx::future< std::ranges::iterator\_t<Rng>>* otherwise. It returns *last*.

template<typename **Iter**, typename **Sent**, typename **OutIter**>  
*reverse\_copy\_result<Iter, OutIter>* **reverse\_copy**(*Iter* first, *Sent* last, *OutIter* result)

Copies the elements from the range  $[first, last)$  to another range beginning at *result* in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(result + (last - first) - 1 - i) = *(first + i)$  once for each non-negative  $i < (last - first)$ . If the source and destination ranges (that is,  $[first, last)$  and  $[result, result+(last-first))$  respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns**

The *reverse\_copy* algorithm returns a *reverse\_copy\_result<Iter, OutIter>*. The *reverse\_copy* algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename OutIter>
reverse_copy_result<std::ranges::iterator_t<Rng>, OutIter> reverse_copy(Rng &&rng, OutIter result)
```

Uses *rng* as the source range, as if using *util::begin(rng)* as *first* and *ranges::end(rng)* as *last*. Copies the elements from the range  $[first, last)$  to another range beginning at *result* in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(result + (last - first) - 1 - i) = *(first + i)$  once for each non-negative  $i < (last - first)$ . If the source and destination ranges (that is,  $[first, last)$  and  $[result, result + (last - first))$  respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns**

The *reverse\_copy* algorithm returns a *ranges::reverse\_copy\_result<std::ranges::iterator\_t<Rng>, OutIter>*. The *reverse\_copy* algorithm returns an object equal to  $\{last, result + N\}$  where  $N = last - first$

```
template<typename ExPolicy, typename Iter, typename Sent, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy, reverse_copy_result<Iter, FwdIter>>::type reverse_copy(ExPolicy
&&pol-
icy,
Iter
first,
Sent
last,
FwdIter
re-
sult)
```

Copies the elements from the range  $[first, last)$  to another range beginning at *result* in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(result + (last - first) - 1 - i) = *(first + i)$  once for each non-negative  $i < (last - first)$ . If the source and destination ranges (that is,  $[first, last)$  and  $[result, result + (last - first))$  respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

#### Returns

The *reverse\_copy* algorithm returns a `hpx::future<reverse_copy_result<Iter, FwdIter> >` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *reverse\_copy\_result<Iter, FwdIter>* otherwise. The *reverse\_copy* algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename OutIter>  
parallel::util::detail::algorithm_result<ExPolicy, reverse_copy_result<std::ranges::iterator_t<Rng>, OutIter>>::type revers
```

Uses *rng* as the source range, as if using `util::begin(rng)` as *first* and `ranges::end(rng)` as *last*. Copies the elements from the range `[first, last)` to another range beginning at *result* in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment `*(result + (last - first) - 1 - i) = *(first + i)` once for each non-negative `i < (last - first)`. If the source and destination ranges (that is, `[first, last)` and `[result, result+(last-first))` respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type

*parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

#### Returns

The *reverse\_copy* algorithm returns a *hpx::future<ranges::reverse\_copy\_result<std::ranges::iterator\_t<Rng>, OutIter>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *ranges::reverse\_copy\_result<std::ranges::iterator\_t<Rng>, OutIter>* otherwise. The *reverse\_copy* algorithm returns an object equal to {last, result + N} where N = last - first

## hpx::ranges::set\_symmetric\_difference

<sup>628</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

*hpx::parallel::util::detail::algorithm\_result<ExPolicy, set\_symmetric\_difference\_result<Iter1, Iter2, Iter3>>::type* **set\_sym**

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges *[first1, last1)* and *[first2, last2)*, but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in *[first1, last1)* and *n* times in *[first2, last2)*, it will be copied to *dest* exactly  $\text{std::abs}(m-n)$  times. If  $m > n$ , then the last  $m-n$  of those elements are copied from *[first1, last1)*, otherwise the last  $n-m$  elements are copied from *[first2, last2)*. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

#### Returns

The *set\_symmetric\_difference* algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. The *set\_symmetric\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred =
hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```

*hpx::parallel::util::detail::algorithm\_result<ExPolicy, set\_symmetric\_difference\_result<std::ranges::iterator\_t<Rng1>, std::*

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges *[first1, last1)* and *[first2, last2)*, but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in *[first1, last1)* and *n* times in *[first2, last2)*, it will be copied to *dest* exactly  $\text{std::abs}(m-n)$  times. If  $m > n$ , then the last  $m-n$  of those elements are copied from *[first1, last1)*, otherwise the last  $n-m$  elements are copied from *[first2, last2)*. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

#### Returns

The *set\_symmetric\_difference* algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. where *Iter1* is `range_iterator_t<Rng1>` and *Iter2* is `range_iterator_t<Rng2>`. The *set\_symmetric\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 =
hpx::identity>
set_symmetric_difference_result<Iter1, Iter2, Iter3> set_symmetric_difference(Iter1 first1, Sent1
                                                                    last1, Iter2 first2,
                                                                    Sent2 last2, Iter3
                                                                    dest, Pred &&op =
                                                                    Pred(), Proj1
                                                                    &&proj1 = Proj1(),
                                                                    Proj2 &&proj2 =
                                                                    Proj2())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges *[first1, last1)* and *[first2, last2)*, but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in *[first1, last1)* and *n* times in *[first2, last2)*, it will be copied to *dest*

exactly `std::abs(m-n)` times. If  $m > n$ , then the last  $m-n$  of those elements are copied from `[first1,last1)`, otherwise the last  $n-m$  elements are copied from `[first2,last2)`. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

#### Template Parameters

- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

#### Returns

The *set\_symmetric\_difference* algorithm returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>`. The *set\_symmetric\_difference* algorithm returns the output iterator to the

element in the destination range, one past the last element copied.

```
template<typename Rng1, typename Rng2, typename Iter3, typename Pred = hpx::parallel::detail::less,
typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
set_symmetric_difference_result<std::ranges::iterator_t<Rng1>, std::ranges::iterator_t<Rng2>, Iter3> set_symmetric_di
```

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges *[first1, last1)* and *[first2, last2)*, but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *f*.

If some element is found *m* times in *[first1, last1)* and *n* times in *[first2, last2)*, it will be copied to *dest* exactly  $\text{std::abs}(m-n)$  times. If  $m > n$ , then the last  $m-n$  of those elements are copied from *[first1, last1)*, otherwise the last  $n-m$  elements are copied from *[first2, last2)*. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

#### Template Parameters

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

#### Parameters

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.

- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *Iter* can be dereferenced and then implicitly converted to *Type1*

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

#### Returns

The *set\_symmetric\_difference* algorithm returns *ranges::set\_symmetric\_difference\_result<Iter1, Iter2, Iter3>*. where *Iter1* is *range\_iterator\_t<Rng1>* and *Iter2* is *range\_iterator\_t<Rng2>*  
The *set\_symmetric\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**hpx::ranges::replace,**  
**hpx::ranges::replace\_copy\_if**

**hpx::ranges::replace\_if,**

**hpx::ranges::replace\_copy,**

Defined in header [hpx/algorithm.hpp](#)<sup>629</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **ranges**

#### Functions

template<typename **Iter**, typename **Sent**, typename **Pred**, typename **Proj** = *hpx::identity*, typename **T** = typename *hpx::parallel::traits::projected<Iter, Proj>::value\_type*>

*Iter* **replace\_if**(*Iter* first, *Sent* sent, *Pred* &&pred, *T* const &new\_value, *Proj* &&proj = *Proj*())

Replaces all elements satisfying specific criteria (for which predicate *f* returns true) with *new\_value* in the range [first, sent).

Effects: Substitutes elements referred by the iterator *it* in the range [first, sent) with *new\_value*, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

The assignments in the parallel *replace\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *sent* - *first* applications of the predicate.

---

<sup>629</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

**Template Parameters**

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for **Iter**.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns**

The *replace\_if* algorithm returns *Iter*. It returns *last*.

```
template<typename Rng, typename Pred, typename Proj = hpx::identity, typename T = typename
hpx::parallel::traits::projected<std::ranges::iterator_t<Rng>, Proj>::value_type>
std::ranges::iterator_t<Rng> replace_if(Rng &&rng, Pred &&pred, T const &new_value, Proj
&&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate *pred* returns true) with *new\_value* in the range *rng*.

Effects: Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

---

**Note:** Complexity: Performs exactly *util::end(rng) - util::begin(rng)* applications of the predicate.

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by *rng*. This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_if* algorithm returns an *hpx::traits::range\_iterator<Rng>::type*. It returns *last*.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename Proj =  
hpx::identity, typename T = typename hpx::parallel::traits::projected<Iter, Proj>::value_type>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> replace_if(ExPolicy &&policy, Iter  
first, Sent sent, Pred  
&&pred, T const  
&new_value, Proj &&proj =  
Proj())
```

Replaces all elements satisfying specific criteria (for which predicate *pred* returns true) with *new\_value* in the range *rng*.

Effects: Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *util::end(rng) - util::begin(rng)* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns**

The *replace\_if* algorithm returns a *hpx::future<Iter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy*. It returns *last*.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::identity,
        typename T = typename hpx::parallel::traits::projected<std::ranges::iterator_t<Rng>, Proj>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, std::ranges::iterator_t<Rng>> replace_if(ExPolicy
                                                                                          &&policy,
                                                                                          Rng
                                                                                          &&rng,
                                                                                          Pred
                                                                                          &&pred, T
                                                                                          const
                                                                                          &new_value,
                                                                                          Proj
                                                                                          &&proj =
                                                                                          Proj())
```

Replaces all elements satisfying specific criteria (for which predicate *pred* returns true) with *new\_value* in the range *rng*.

Effects: Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *util::end(rng) - util::begin(rng)* applications of the predicate.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by *rng*. This is a unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_if* algorithm returns a *hpx::future<std::ranges::iterator\_t<Rng>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy*. It returns *last*.

```
template<typename Iter, typename Sent, typename Proj = hpx::identity, typename T1 = typename
hpx::parallel::traits::projected<Iter, Proj>::value_type, typename T2 = T1>
```

```
Iter replace(Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with *new\_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator *it* in the range [first,last) with *new\_value*, when the following corresponding conditions hold: *INVOKE(proj, \*i) == old\_value*

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns**

The *replace* algorithm returns an *Iter*.

```
template<typename Rng, typename Proj = hpx::identity, typename T1 = typename
hpx::parallel::traits::projected<std::ranges::iterator_t<Rng>, Proj>::value_type, typename T2 = T1>
std::ranges::iterator_t<Rng> replace(Rng &&rng, T1 const &old_value, T2 const &new_value, Proj
&&proj = Proj())
```

Replaces all elements satisfying specific criteria with *new\_value* in the range *rng*.

Effects: Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` assignments.

---

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

**Returns**

The *replace* algorithm returns an `hpx::traits::range_iterator<Rng>::type`.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Proj = hpx::identity,
typename T1 = typename hpx::parallel::traits::projected<Iter, Proj>::value_type, typename T2 = T1>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> replace(ExPolicy &&policy, Iter first,
Sent sent, T1 const &old_value,
T2 const &new_value, Proj
&&proj = Proj())
```

Replaces all elements satisfying specific criteria with *new\_value* in the range `[first, last)`.

Effects: Substitutes elements referred by the iterator *it* in the range `[first,last)` with *new\_value*, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace* algorithm returns a *hpx::future<Iter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *Iter* otherwise.

```
template<typename ExPolicy, typename Rng, typename Proj = hpx::identity, typename T1 = typename
hpx::parallel::traits::projected<std::ranges::iterator_t<Rng>, Proj>::value_type, typename T2 = T1>
parallel::util::detail::algorithm_result<ExPolicy, std::ranges::iterator_t<Rng>> replace(ExPolicy
&&policy, Rng
&&rng, T1
const
&old_value, T2
const
&new_value,
Proj &&proj =
Proj())
```

Replaces all elements satisfying specific criteria with *new\_value* in the range *rng*.

Effects: Substitutes elements referred by the iterator *it* in the range *rng* with *new\_value*, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *util::end(rng) - util::begin(rng)* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked. The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

#### Returns

The *replace* algorithm returns an *hpx::future<hpx::traits::range\_iterator<Rng>::type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *hpx::traits::range\_iterator<Rng>::type* otherwise.

```
template<typename InIter, typename Sent, typename OutIter, typename Pred, typename T =
typename std::iterator_traits<OutIter>::value_type, typename Proj = hpx::identity>
replace_copy_if_result<InIter, OutIter> replace_copy_if(InIter first, Sent sent, OutIter dest, Pred
&&pred, T const &new_value, Proj
&&proj = Proj())
```

Copies the all elements from the range [first, sent) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (sent - first)) either *new\_value* or *\*(first + (it - result))* depending on whether the following corresponding condition holds: *INVOKE(f, INVOKE(proj, \*(first + (i - result)))) != false*

The assignments in the parallel *replace\_copy\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *sent - first* applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *InIter*.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyCon-*

*structible*. (deduced).

- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_copy\_if* algorithm returns a *in\_out\_result<InIter, OutIter>*. The *replace\_copy\_if* algorithm returns the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename OutIter, typename Pred, typename T = typename
std::iterator_traits<OutIter>::value_type, typename Proj = hpx::identity>
replace_copy_if_result<std::ranges::iterator_t<Rng>, OutIter> replace_copy_if(Rng &&rng, OutIter
dest, Pred &&pred,
T const &new_value,
Proj &&proj =
Proj())
```

Copies the all elements from the range *rng* to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator *it* in the range [*result*, *result* + (*util::end(rng)* - *util::begin(rng)*)) either *new\_value* or *\*(first + (it - result))* depending on whether the following corresponding condition holds: *INVOKE(f, INVOKE(proj, \*(first + (i - result)))) != false*

The assignments in the parallel *replace\_copy\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *util::end(rng)* - *util::begin(rng)* applications of the predicate.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).

- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_copy\_if* algorithm returns an *in\_out\_result*<*std::ranges::iterator\_t*<*Rng*>, *OutIter*>. The *replace\_copy\_if* algorithm returns the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename
Pred, typename T = typename std::iterator_traits<FwdIter2>::value_type, typename Proj =
hpx::identity>
```

```
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_if_result<FwdIter1, FwdIter2>>::type replace_copy_if(
```

Copies the all elements from the range [first, sent) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (sent - first)) either *new\_value* or *\*(first + (it - result))* depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel *replace\_copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *sent - first* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *InIter*.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_copy\_if* algorithm returns an *hpx::future<FwdIter1, FwdIter2>*. The *replace\_copy\_if* algorithm returns the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter, typename Pred, typename T =
typename std::iterator_traits<FwdIter>::value_type, typename Proj = hpx::identity>
```

*parallel::util::detail::algorithm\_result<ExPolicy, replace\_copy\_if\_result<std::ranges::iterator\_t<Rng>, FwdIter>>::type* **rep**

Copies the all elements from the range *rng* to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator *it* in the range  $[result, result + (util::end(rng) - util::begin(rng))]$  either *new\_value* or  $*(first + (it - result))$  depending on whether the following corresponding condition holds:  $INVOKE(f, INVOKE(proj, *(first + (i - result)))) \neq false$

The assignments in the parallel *replace\_copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly  $util::end(rng) - util::begin(rng)$  applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by  $[first, last)$ . This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_copy\_if* algorithm returns an `hpx::future<in_out_result<std::ranges::iterator_t<Rng>, OutIter>>`. The *replace\_copy\_if* algorithm returns the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename Sent, typename OutIter, typename Proj = hpx::identity,
typename T1 = typename hpx::parallel::traits::projected<InIter, Proj>::value_type, typename T2 = T1>
replace_copy_result<InIter, OutIter> replace_copy(InIter first, Sent sent, OutIter dest, T1 const
&old_value, T2 const &new_value, Proj &&proj
= Proj())
```

Copies the all elements from the range [first, sent) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (sent - first)) either *new\_value* or *\*(first + (it - result))* depending on whether the following corresponding condition holds: `INVOKE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel *replace\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *sent - first* applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for *Iter*.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_copy* algorithm returns an `in_out_result<InIter, OutIter>`. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the

destination range, one past the last element copied.

```
template<typename Rng, typename OutIter, typename Proj = hpx::identity, typename T1 = typename
hpx::parallel::traits::projected<std::ranges::iterator_t<Rng>, Proj>::value_type, typename T2 = T1>
replace_copy_result<std::ranges::iterator_t<Rng>, OutIter> replace_copy(Rng &&rng, OutIter dest,
                                                                    T1 const &old_value, T2
                                                                    const &new_value, Proj
                                                                    &&proj = Proj())
```

Copies the all elements from the range *rbg* to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range  $[\text{result}, \text{result} + (\text{util::end}(\text{rng}) - \text{util::begin}(\text{rng}))]$  either *new\_value* or  $*(\text{first} + (\text{it} - \text{result}))$  depending on whether the following corresponding condition holds:  $\text{INVOKE}(\text{proj}, *(\text{first} + (\text{i} - \text{result}))) == \text{old\_value}$

The assignments in the parallel *replace\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly  $\text{util::end}(\text{rng}) - \text{util::begin}(\text{rng})$  applications of the predicate.

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_copy* algorithm returns an *in\_out\_result<std::ranges::iterator\_t<Rng>, OutIter>*. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename
Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<FwdIter1,
Proj>::value_type, typename T2 = T1>
```

```
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_result<FwdIter1, FwdIter2>>::type replace_copy(ExPolicy&&pol  
icy,  
FwdIter  
first,  
Sent  
sent,  
FwdIter  
dest,  
T1  
const  
&old_v  
T2  
const  
&new_  
Proj  
&&pro  
=  
Proj())
```

Copies the all elements from the range [first, sent) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (sent - first)) either new\_value or \*(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(proj, \*(first + (i - result))) == old\_value

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *sent - first* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *replace\_copy* algorithm returns a `hpx::future<in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `in_out_result<FwdIter1, FwdIter2>` otherwise. The *copy* algorithm returns the pair of the forward iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter, typename Proj = hpx::identity,
        typename T1 = typename hpx::parallel::traits::projected<std::ranges::iterator_t<Rng>,
        Proj>::value_type, typename T2 = T1>
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_result<std::ranges::iterator_t<Rng>, FwdIter>>>::type repla
```

Copies the all elements from the range *rbg* to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator *it* in the range `[result, result + (util::end(rng) - util::begin(rng))]` either *new\_value* or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The `replace_copy` algorithm returns a `hpx::future<in_out_result<std::ranges::iterator_t<Rng>, FwdIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `in_out_result<std::ranges::iterator_t<Rng>, FwdIter>>` The `copy` algorithm returns the pair of the input iterator *last* and the forward iterator to the element in the destination range, one past the last element copied.

## hpx::ranges::equal

Defined in header `hpx/algorithm.hpp`<sup>630</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, Iter1 first1,
                                                                    Sent1 last1, Iter2 first2, Sent2
                                                                    last2, Pred &&op = Pred(), Proj1
                                                                    &&proj1 = Proj1(), Proj2
                                                                    &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

<sup>630</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate  $f$ .

---

---

**Note:** The two ranges are considered equal if, for every iterator  $i$  in the range  $[\text{first1}, \text{last1})$ ,  $*i$  equals  $*(\text{first2} + (i - \text{first1}))$ . This overload of `equal` uses `operator==` to determine if two elements are equal.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `hpx::identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

#### Returns

The *equal* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range  $[\text{first1}, \text{last1})$  does not equal the length of the range  $[\text{first2}, \text{last2})$ ,

it returns false.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename
Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, Rng1
&&rng1, Rng2 &&rng2, Pred
&&op = Pred(), Proj1 &&proj1 =
Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last1 - first1* applications of the predicate *f*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1,last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses operator== to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

#### Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred =
equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
bool equal(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 =
Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

---

**Note:** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *f*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1,last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses operator== to determine if two elements are equal.

---

#### Template Parameters

- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to *hpx::identity*
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to *hpx::identity*

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1*

and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

#### Returns

The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```
template<typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::identity,
        typename Proj2 = hpx::identity>
bool equal(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2
          &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise.

---

**Note:** Complexity: At most *last1 - first1* applications of the predicate *f*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1,last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses operator== to determine if two elements are equal.

---

#### Template Parameters

- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `hpx::identity`

#### Parameters

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate *is* invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate *is* invoked.

**Returns**

The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

**hpx::ranges::all\_of, hpx::ranges::any\_of, hpx::ranges::none\_of**

Defined in header `hpx/algorithm.hpp`<sup>631</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

**Functions**

```
template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> none_of(ExPolicy &&policy, Rng
&&rng, F &&f, Proj &&proj =
Proj())
```

Checks if unary predicate *f* returns true for no elements in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *Copy-Constructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

---

<sup>631</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *none\_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj =
hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> none_of(ExPolicy &&policy, Iter first,
                                                                    Sent last, F &&f, Proj &&proj
                                                                    = Proj())
```

Checks if unary predicate *f* returns true for no elements in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *Iter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *none\_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Rng, typename F, typename Proj = hpx::identity>
bool none_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for no elements in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
bool none_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for no elements in the range [first, last).

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential

form, the parallel overload of *none\_of* requires *F* to meet the requirements of *Copy-Constructible*.

- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> any_of(ExPolicy &&policy, Rng &&rng,
                                                                    F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *Copy-Constructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *any\_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj =
hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> any_of(ExPolicy &&policy, Iter first,
                                                                    Sent last, F &&f, Proj &&proj =
                                                                    Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *any\_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename Rng, typename F, typename Proj = hpx::identity>
bool any_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
bool any_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for at least one element in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential

form, the parallel overload of *none\_of* requires *F* to meet the requirements of *Copy-Constructible*.

- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> all_of(ExPolicy &&policy, Rng &&rng,
                                                                    F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *Copy-Constructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *all\_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj =
hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> all_of(ExPolicy &&policy, Iter first,
                                                                    Sent last, F &&f, Proj &&proj =
                                                                    Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *all\_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Rng, typename F, typename Proj = hpx::identity>
bool all_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
bool all_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate *f* returns true for all elements in the range *rng*.

---

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate *f*

---

#### Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *InIter*.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential

form, the parallel overload of *none\_of* requires *F* to meet the requirements of *Copy-Constructible*.

- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

## hpx::ranges::exclusive\_scan

Defined in header `hpx/algorithm.hpp`<sup>632</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter, typename Sent, typename OutIter, typename T = typename
std::iterator_traits<InIter>::value_type, typename Op = std::plus<T>>
exclusive_scan_result<InIter, OutIter> exclusive_scan(InIter first, Sent last, OutIter dest, T init, Op
&&op = Op())
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, \*first, ..., \*(first + (i - result) - 1)).

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

---

<sup>632</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when `N` is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter1`.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

#### Returns

The *exclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename T
= typename std::iterator_traits<FwdIter1>::value_type, typename Op = std::plus<T>>
parallel::util::detail::algorithm_result<ExPolicy, exclusive_scan_result<FwdIter1, FwdIter2>>::type exclusive_scan(Ex
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERAL-`

IZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, \*first, ..., \*(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a1*, ..., *aN*) is defined as:

- *a1* when *N* is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a1*, ..., *aK*), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *aM*, ..., *aN*)) where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter1*.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns**

The *exclusive\_scan* algorithm returns a `hpx::future<util::in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `util::in_out_result<FwdIter1, FwdIter2>` otherwise. The *exclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename O, typename T = typename
std::iterator_traits<std::ranges::iterator_t<Rng>>::value_type, typename Op = std::plus<T>>
exclusive_scan_result<std::ranges::iterator_t<Rng>, O> exclusive_scan(Rng &&rng, O dest, T init,
                                                                    Op &&op = Op())
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, ..., *(first + (i - result) - 1))`

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate `std::plus<T>`.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN)` is defined as:

- `a1` when `N` is 1
  - `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK)`
    - `GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN)` where  $1 < K+1 = M \leq N$ .
- 

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns**

The *exclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename O, typename T = typename
std::iterator_traits<std::ranges::iterator_t<Rng>>::value_type, typename Op = std::plus<T>>
```

*parallel::util::detail::algorithm\_result<ExPolicy, exclusive\_scan\_result<std::ranges::iterator\_t<Rng>, O>> exclusive\_sca*

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, init, \*first, ..., \*(first + (i - result) - 1))

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *std::plus<T>*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate

should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

#### Returns

The *exclusive\_scan* algorithm returns a `hpx::future<util::in_out_result<std::ranges::iterator_t<Rng>, O>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `util::in_out_result<std::ranges::iterator_t<Rng>, O>` otherwise. The *exclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

## hpx::ranges::transform\_inclusive\_scan

Defined in header `hpx/algorithm.hpp`<sup>633</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```
template<typename InIter, typename Sent, typename OutIter, typename BinOp, typename UnOp>
transform_inclusive_scan_result<InIter, OutIter> transform_inclusive_scan(InIter first, Sent last,
                                                                           OutIter dest, BinOp
                                                                           &&binary_op, UnOp
                                                                           &&unary_op)
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result))))`.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges `[first,last)` or `[result,result + (last - first))`.

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *op* and *conv*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when *N* is 1

---

<sup>633</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN) where  $1 < K+1 = M \leq N$ .`

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for **InIter**.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

### Returns

The *transform\_inclusive\_scan* algorithm returns *transform\_inclusive\_scan\_result<InIter, OutIter>*. The *transform\_inclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename BinOp, typename UnOp>
```

---

*parallel::util::detail::algorithm\_result<ExPolicy, transform\_inclusive\_result<FwdIter1, FwdIter2>>::type* **transform\_inc**

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result))))`.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- $a1$  when  $N$  is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

#### Returns

The *transform\_inclusive\_scan* algorithm returns a `hpx::future<transform_inclusive_result<FwdIter1, FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *transform\_inclusive\_result<FwdIter1, FwdIter2>* otherwise. The *transform\_inclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename O, typename BinOp, typename UnOp>
transform_inclusive_scan_result<std::ranges::iterator_t<Rng>, O> transform_inclusive_scan(Rng
                                                                                               &&rng,
                                                                                               O
                                                                                               dest,
                                                                                               BinOp
                                                                                               &&bi-
                                                                                               nary_op,
                                                                                               UnOp
                                                                                               &&unary_op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result))))`.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *op* and *conv*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when `N` is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **O** – The type of the iterator representing the destination range (deduced).
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

#### Returns

The `transform_inclusive_scan` algorithm returns a `transform_inclusive_scan_result< std::ranges::iterator_t<Rng>, O>`. The `transform_inclusive_scan` algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename O, typename BinOp, typename UnOp>
```

*parallel::util::detail::algorithm\_result<ExPolicy, transform\_inclusive\_scan\_result<std::ranges::iterator\_t<Rng>, O>>::type*

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result))))`.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- $a1$  when  $N$  is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator. This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

#### Returns

The *transform\_inclusive\_scan* algorithm returns a `hpx::future<transform_inclusive_scan_result<std::ranges::iterator_t<Rng>, O>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *transform\_inclusive\_scan\_result<std::ranges::iterator\_t<Rng>, O>* otherwise. The *transform\_inclusive\_scan* algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename Sent, typename OutIter, typename BinOp, typename UnOp,
typename T = typename std::iterator_traits<InIter>::value_type>
transform_inclusive_scan_result<InIter, OutIter> transform_inclusive_scan(InIter first, Sent last,
                                                                    OutIter dest, BinOp
                                                                    &&binary_op, UnOp
                                                                    &&unary_op, T init)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *op* and *conv*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aN) is defined as:

- a1 when N is 1
  - op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
-

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.

**Returns**

The *transform\_inclusive\_scan* algorithm returns *transform\_inclusive\_scan\_result<InIter, OutIter>*. The *transform\_inclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename BinOp, typename UnOp, typename T = typename std::iterator_traits<FwdIter1>::value_type>
```

---

*parallel::util::detail::algorithm\_result<ExPolicy, transform\_inclusive\_result<FwdIter1, FwdIter2>>::type* **transform\_inc**

Assigns through each iterator  $i$  in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), ..., conv(*(first + (i - result))))`.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- $a1$  when  $N$  is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.

- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.

#### Returns

The *transform\_inclusive\_scan* algorithm returns a *hpx::future<transform\_inclusive\_result<FwdIter1, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *transform\_inclusive\_result<FwdIter1, FwdIter2>* otherwise. The *transform\_inclusive\_scan* algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename O, typename BinOp, typename UnOp, typename T = typename
std::iterator_traits<std::ranges::iterator_t<Rng>>::value_type>
transform_inclusive_scan_result<std::ranges::iterator_t<Rng>, O> transform_inclusive_scan(Rng
&&rng,
O
dest,
BinOp
&&binary_op,
UnOp
&&unary_op,
T
init)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of `transform_inclusive_scan` may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicates *op* and *conv*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- $a1$  when  $N$  is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **O** – The type of the iterator representing the destination range (deduced).
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by  $[first, last)$ . This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.

#### Returns

The `transform_inclusive_scan` algorithm returns a `transform_inclusive_scan_result< std::ranges::iterator_t<Rng>, O>`. The `transform_inclusive_scan` algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename O, typename BinOp, typename UnOp, typename
T = typename std::iterator_traits<std::ranges::iterator_t<Rng>>::value_type>
```

*parallel::util::detail::algorithm\_result<ExPolicy, transform\_inclusive\_scan\_result<std::ranges::iterator\_t<Rng>, O>>::type*

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *conv* nor *op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of *transform\_inclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *op* and *conv*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aN) is defined as:

- a1 when N is 1
  - op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, aM, ..., aN) where  $1 < K+1 = M \leq N$ ).
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator. This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of the binary function object used for the reduction operation.
- **UnOp** – The type of the unary function object used for the conversion operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **unary\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

- **init** – The initial value for the generalized sum.

#### Returns

The *transform\_inclusive\_scan* algorithm returns a *hpx::future<transform\_inclusive\_scan\_result<std::ranges::iterator\_t<Rng>, O>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *transform\_inclusive\_scan\_result<std::ranges::iterator\_t<Rng>, O>* otherwise. The *transform\_inclusive\_scan* algorithm returns an input iterator to one past the end of the range and an output iterator to the element in the destination range, one past the last element copied.

## hpx/parallel/util/range.hpp

Defined in header `hpx/parallel/util/range.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **parallel**

namespace **util**

## Typedefs

```
template<typename Iterator, typename Sentinel = Iterator>
using range = hpx::util::iterator_range<Iterator, Sentinel>
```

## Functions

```
template<typename Iter, typename Sent>
range<Iter, Sent> concat(range<Iter, Sent> const &it1, range<Iter, Sent> const &it2)

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2>
range<Iter2, Iter2> init_move(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const &src)
```

Move objects from the range src to dest.

### Parameters

- **dest** – [in] : range where move the objects
- **src** – [in] : range from where move the objects

### Returns

range with the objects moved and the size adjusted

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2>
range<Iter2, Sent2> uninit_move(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const
                                &src)
```

Move objects from the range src creating them in dest.

### Parameters

- **dest** – [in] : range where move and create the objects
- **src** – [in] : range from where move the objects

### Returns

range with the objects moved and the size adjusted

```
template<typename Iter, typename Sent>
void destroy_range(range<Iter, Sent> r)
```

destroy a range of objects

### Parameters

**r** – [in] : range to destroy

```
template<typename Iter, typename Sent>
range<Iter, Sent> init(range<Iter, Sent> const &r, typename std::iterator_traits<Iter>::value_type
                      &val)
```

initialize a range of objects with the object val moving across them

### Parameters

- **r** – [in] : range of elements not initialized
- **val** – [in] : object used for the initialization

### Returns

range initialized

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename
Compare>
bool is_mergeable(range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2, Compare
                  comp)
```

: indicate if two ranges have a possible merge

---

**Remark**

---

**Parameters**

- **src1** – [in] : first range
- **src2** – [in] : second range
- **comp** – [in] : object for to compare elements

**Returns**

true : they can be merged false : they can't be merged

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
typename Sent3, typename Compare>
```

```
range<Iter3, Sent3> full_merge(range<Iter3, Sent3> const &dest, range<Iter1, Sent1> const
&src1, range<Iter2, Sent2> const &src2, Compare comp)
```

Merge two contiguous ranges src1 and src2 , and put the result in the range dest, returning the range merged.

**Parameters**

- **dest** – [in] : range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2
- **src1** – [in] : first range to merge
- **src2** – [in] : second range to merge
- **comp** – [in] : comparison object

**Returns**

range with the elements merged and the size adjusted

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Value,
typename Compare>
```

```
range<Value*> uninit_full_merge(range<Value*> const &dest, range<Iter1, Sent1> const
&src1, range<Iter2, Sent2> const &src2, Compare comp)
```

Merge two contiguous ranges src1 and src2 , and create and move the result in the uninitialized range dest, returning the range merged.

**Parameters**

- **dest** – [in] : range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2. Initially is un-initialize memory
- **src1** – [in] : first range to merge
- **src2** – [in] : second range to merge
- **comp** – [in] : comparison object

**Returns**

range with the elements merged and the size adjusted

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename
Compare>
```

```
range<Iter2, Sent2> half_merge(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const
&src1, range<Iter2, Sent2> const &src2, Compare comp)
```

: Merge two buffers. The first buffer is in a separate memory

**Parameters**

- **dest** – [in] : range where finish the two buffers merged
- **src1** – [in] : first range to merge in a separate memory
- **src2** – [in] : second range to merge, in the final part of the range where deposit the final results
- **comp** – [in] : object for compare two elements of the type pointed by the Iter1 and Iter2

**Returns**

: range with the two buffers merged

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,  
typename Sent3, typename Compare>
```

```
bool in_place_merge_uncontiguous(range<Iter1, Sent1> const &src1, range<Iter2, Sent2>  
                                const &src2, range<Iter3, Sent3> &aux, Compare comp)
```

: merge two non contiguous buffers src1 , src2, using the range aux as auxiliary memory

---

**Remark**

---

**Parameters**

- **src1** – [**in**] : first range to merge
- **src2** – [**in**] : second range to merge
- **aux** – [**in**] : auxiliary range used in the merge
- **comp** – [**in**] : object for to compare elements

**Returns**

true : not changes done false : changes in the buffers

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename  
Compare>
```

```
range<Iter1, Sent1> in_place_merge(range<Iter1, Sent1> const &src1, range<Iter1, Sent1> const  
                                &src2, range<Iter2, Sent2> &buf, Compare comp)
```

: merge two contiguous buffers ( src1, src2) using buf as auxiliary memory

---

**Remark**

---

**Parameters**

- **src1** – [**in**] : first range to merge
- **src2** – [**in**] : second range to merge
- **buf** – [**in**] : auxiliary memory used in the merge
- **comp** – [**in**] : object for to compare elements

**Returns**

true : not changes done false : changes in the buffers

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename  
Compare>
```

```
void merge_flow(range<Iter1, Sent1> rng1, range<Iter2, Sent2> rbuf, range<Iter1, Sent1> rng2,  
                Compare cmp)
```

## hpx::reduce\_by\_key

Defined in header `hpx/algorithm.hpp`<sup>634</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

### Functions

```

template<typename ExPolicy, typename RanIter, typename RanIter2, typename FwdIter1,
typename FwdIter2, typename Compare = std::equal_to<typename
std::iterator_traits<RanIter>::value_type>, typename Func = std::plus<typename
std::iterator_traits<RanIter2>::value_type>>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type reduce_by_key(ExPolicy
&&pol-
icy,
Ran-
Iter
key_first,
Ran-
Iter
key_last,
Ran-
Iter2
val-
ues_first,
FwdIter1
keys_output,
FwdIter2
val-
ues_output,
Com-
pare
&&comp
=
Com-
pare(),
Func
&&func
=
Func())

```

Reduce by Key performs an inclusive scan reduction operation on elements supplied in key/value pairs. The algorithm produces a single output value for each set of equal consecutive keys in [key\_first, key\_last). the value being the GENERALIZED\_NONCOMMUTATIVE\_SUM(op, init, \*first, ..., \*(first + (i - result))). for the run of consecutive matching keys. The number of keys supplied must match the number of values.

<sup>634</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RanIter** – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **RanIter2** – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **FwdIter1** – The type of the iterator representing the destination key range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination value range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Compare** – The type of the optional function/function object to use to compare keys (deduced). Assumed to be `std::equal_to` otherwise.
- **Func** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce\_by\_key* requires *Func* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **key\_first** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key\_last** – Refers to the end of the sequence of key elements the algorithm will be applied to.
- **values\_first** – Refers to the beginning of the sequence of value elements the algorithm will be applied to.
- **keys\_output** – Refers to the start output location for the keys produced by the algorithm.
- **values\_output** – Refers to the start output location for the values produced by the algorithm.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to `bool`, yields `true` if the first argument of the call is less than the second, and `false` otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **func** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by *[first, last)*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

#### Returns

The *reduce\_by\_key* algorithm returns a `hpx::future<pair<Iter1,Iter2>>` if the exe-

cution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *pair<Iter1,Iter2>* otherwise.

## hpx::nth\_element

Defined in header [hpx/algorithm.hpp](#)<sup>635</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename RandomIt, typename Pred = hpx::parallel::detail::less>
void nth_element(RandomIt first, RandomIt nth, RandomIt last, Pred &&pred = Pred())
```

*nth\_element* is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by *nth* is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new *nth* element are less than or equal to the elements after the new *nth* element. Executed according to the policy.

The comparison operations in the parallel *nth\_element* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in `std::distance(first, last)` on average.  $O(N)$  applications of the predicate, and  $O(N \log N)$  swaps, where  $N = \text{last} - \text{first}$ .

---

### Template Parameters

- **RandomIt** – The type of the source begin, *nth*, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to `std::less<>`.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to *Type*. This defaults to `std::less<>`.

---

<sup>635</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

### Returns

The *nth\_element* algorithms returns nothing.

```
template<typename ExPolicy, typename RandomIt, typename Pred = hpx::parallel::detail::less>
void nth_element(ExPolicy &&policy, RandomIt first, RandomIt nth, RandomIt last, Pred &&pred =
    Pred())
```

*nth\_element* is a partial sorting algorithm that rearranges elements in  $[first, last)$  such that the element pointed at by *nth* is changed to whatever element would occur in that position if  $[first, last)$  were sorted and all of the elements before this new *nth* element are less than or equal to the elements after the new *nth* element.

The comparison operations in the parallel *nth\_element* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *nth\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in  $\text{std::distance}(first, last)$  on average.  $O(N)$  applications of the predicate, and  $O(N \log N)$  swaps, where  $N = last - first$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source begin, *nth*, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to `std::less<>`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to *Type*. This defaults to `std::less<>`.

### Returns

The *nth\_element* algorithms returns nothing.

**hpx::experimental::for\_loop**, **hpx::experimental::for\_loop\_strided**, **hpx::experimental::for\_loop\_n**, **hpx::experimental::for\_loop\_n\_strided**

Defined in header `hpx/algorithm.hpp`<sup>636</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

## Functions

```
template<typename I, typename ...Args>
void for_loop(std::decay_t<I> first, I last, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last* - *first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

<sup>636</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

#### Template Parameters

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename ...Args>
auto for_loop(ExPolicy &&policy, std::decay_t<I> first, I last, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires:  $I$  shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of *MoveConstructible*.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last* - *first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding  $f$ , an additional argument is passed to each application of  $f$  as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of  $f$  in the input sequence.

Complexity: Applies  $f$  exactly once for each element of the input sequence.

Remarks: If  $f$  returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

### Returns

The `for_loop` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```
template<typename I, typename S, typename ...Args>
void for_loop_strided(std::decay_t<I> first, I last, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires:  $I$  shall be an integral type or meet the requirements of an input iterator type. The  $args$  parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of *MoveConstructible*.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the  $args$  parameter pack. The length of the input sequence is  $last - first$ .

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

#### Template Parameters

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if *I* has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [*first*, *last*) should expose a signature equivalent to:

`<ignored> pred(I const& a, ...);`

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename S, typename ...Args>
auto for_loop_strided(ExPolicy &&policy, std::decay_t<I> first, I last, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using *advance* and *distance*.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if *I* has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [*first*, *last*) should expose a signature equivalent to:

`<ignored> pred(I const& a, ...);`

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns**

The *for\_loop\_strided* algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

template<typename **I**, typename **Size**, typename ...**Args**>  
void **for\_loop\_n**(I first, Size size, Args&&... args)

The *for\_loop\_n* implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble *for\_each* from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of *for\_loop\_n* without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

**Template Parameters**

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.

- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename Size, typename ...Args>
auto for_loop_n(ExPolicy &&policy, I first, Size size, Args&&... args)
```

The `for_loop_n` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last* - *first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of  $f$ , even though the applications themselves may be unordered.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

#### Returns

The `for_loop_n` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```
template<typename I, typename Size, typename S, typename ...Args>
void for_loop_n_strided(I first, Size size, S stride, Args&&... args)
```

The `for_loop_n_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires:  $I$  shall be an integral type or meet the requirements of an input iterator type. The  $args$  parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function,  $f$ .  $f$  shall meet the requirements of *MoveConstructible*.

Effects: Applies  $f$  to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the  $args$  parameter pack. The length of the input sequence is  $last - first$ .

The first element in the input sequence is specified by  $first$ . Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

#### Template Parameters

- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if *I* has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```
template<typename ExPolicy, typename I, typename Size, typename S, typename ...Args>
auto for_loop_n_strided(ExPolicy &&policy, I first, Size size, S stride, Args&&... args)
```

The `for_loop_n_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using *advance* and *distance*.

---

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if *I* has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [*first*, *last*) should expose a signature equivalent to:

```
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

#### Returns

The *for\_loop\_n\_strided* algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

## hpx::move

Defined in header `hpx/algorithm.hpp`<sup>637</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> move(ExPolicy &&policy, FwdIter1 first,
                                                                    FwdIter1 last, FwdIter2 dest)
```

Moves the elements in the range `[first, last)`, to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move. Executed according to the policy.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* move assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the move assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

---

<sup>637</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns**

The *move* algorithm returns a *hpx::future<FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```
template<typename FwdIter1, typename FwdIter2>  
FwdIter2 move(FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Moves the elements in the range [first, last), to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

---

**Note:** Complexity: Performs exactly *last - first* move assignments.

---

**Template Parameters**

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns**

The *move* algorithm returns a *FwdIter2*. The *move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

**hpx::starts\_with**

Defined in header `hpx/algorithm.hpp`<sup>638</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

<sup>638</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename InIter1, typename InIter2, typename Pred = hpx::parallel::detail::equal_to>
bool starts_with(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred = Pred())
```

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2)

The assignments in the parallel *starts\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate.

---

### Template Parameters

- **InIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The binary predicate that compares the elements. This defaults to *hpx::parallel::detail::equal\_to*.

### Parameters

- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

### Returns

The *starts\_with* algorithm returns *bool*. The *starts\_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

```
template<typename ExPolicy, typename InIter1, typename InIter2, typename Pred = ranges::equal_to>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> starts_with(ExPolicy &&policy, InIter1
    first1, InIter1 last1, InIter2
    first2, InIter2 last2, Pred
    &&pred = Pred())
```

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2). Executed according to the policy.

The assignments in the parallel *starts\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **InIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The binary predicate that compares the elements. This defaults to *ranges::equal\_to*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

### Returns

The *starts\_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *starts\_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

## hpx::remove\_copy, hpx::remove\_copy\_if

Defined in header [hpx/algorithm.hpp](#)<sup>639</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename OutIter, typename T = typename
std::iterator_traits<InIter>::value_type>
OutIter remove_copy(InIter first, InIter last, OutIter dest, T const &value)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: *\*it == value*

The assignments in the parallel *remove\_copy* algorithm execute in sequential order in the calling thread.

---

<sup>639</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*, here comparison operator.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type that the result of dereferencing *FwdIter1* is compared to.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **value** – Value to be removed.

### Returns

The *remove\_copy* algorithm returns an *OutIter*. The *remove\_copy* algorithm returns the iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T = typename
std::iterator_traits<InIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> remove_copy(ExPolicy &&policy,
                                          FwdIter1 first, FwdIter1
                                          last, FwdIter2 dest, T const
                                          &value)
```

Copies the elements in the range, defined by *[first, last)*, to another range beginning at *dest*. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved. Executed according to the policy.

Effects: Copies all the elements referred to by the iterator it in the range *[first,last)* for which the following corresponding conditions do not hold: *\*it == value*

The assignments in the parallel *remove\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*, here comparison operator.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type that the result of dereferencing FwdIter1 is compared to.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **value** – Value to be removed.

#### Returns

The *remove\_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *remove\_copy* algorithm returns the iterator to the element past the last element copied.

```
template<typename InIter, typename OutIter, typename Pred>  
OutIter remove_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *pred* returns false. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: `INVOKE(pred, *it) != false`.

The assignments in the parallel *remove\_copy\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *remove\_copy\_if* algorithm returns an *OutIter*. The *remove\_copy\_if* algorithm returns the iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> remove_copy_if(ExPolicy &&policy,
                                                                                   FwdIter1 first,
                                                                                   FwdIter1 last, FwdIter2
                                                                                   dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *pred* returns false. The order of the elements that are not removed is preserved. Executed according to the policy.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: `INVOKE(pred, *it) != false`.

The assignments in the parallel *remove\_copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove\_copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_copy\_if* requires *Pred* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *remove\_copy\_if* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *remove\_copy\_if* algorithm returns the iterator to the element past the last element copied.

## hpx/parallel/algorithms/iota.hpp

Defined in header `hpx/parallel/algorithms/iota.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Sent, typename T>  
void iota(FwdIter first, Sent last, T value)
```

Fills the range [first, last) with sequentially increasing values, starting with *value* and repetitively evaluating `++value`.

The assignments in the *iota* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly `std::distance(first, last)` assignments and increments.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input or output iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for *FwdIter*.

- **T** – The type of the value to be assigned (deduced). This type must be weakly incrementable.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be stored in the first element.

#### Returns

The *iota* algorithm returns *void*.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename T>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> iota(ExPolicy &&policy, FwdIter first, Sent last, T
value)
```

Fills the range [first, last) with sequentially increasing values, starting with *value* and repetitively evaluating ++*value*.

The assignments in the parallel *iota* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *iota* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *std::distance(first, last)* assignments and increments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **T** – The type of the value to be assigned (deduced). This type must be weakly incrementable.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be stored in the first element.

#### Returns

The *iota* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

## hpx::shift\_right

Defined in header [hpx/algorithm.hpp](#)<sup>640</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Size>  
FwdIter shift_right(FwdIter first, FwdIter last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i.

The assignment operations in the parallel *shift\_right* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

### Returns

The *shift\_right* algorithm returns *FwdIter*. The *shift\_right* algorithm returns an iterator to the beginning of the resulting range. Specifically: If *n* is 0 or *n* >= (last - first), does nothing and returns *first* and *last* respectively. Otherwise returns *first* + n.

```
template<typename ExPolicy, typename FwdIter, typename Size>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter> shift_right(ExPolicy &&policy, FwdIter  
first, FwdIter last, Size n)
```

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

---

<sup>640</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- $n + i$ . Executed according to the policy.

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_right* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most (last - first) - n assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

### Returns

The *shift\_right* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *shift\_right* algorithm returns an iterator to the beginning of the resulting range. Specifically: If *n* is 0, does nothing and returns *first*. If  $n \geq (\text{last} - \text{first})$ , does nothing and returns *last*. Otherwise returns *first* + *n*.

## hpx::is\_partitioned

Defined in header [hpx/algorithm.hpp](#)<sup>641</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

---

<sup>641</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

template<typename **FwdIter**, typename **Pred**>  
bool **is\_partitioned**(*FwdIter* first, *FwdIter* last, *Pred* &&pred)

Determines if the range [first, last) is partitioned.

---

**Note:** Complexity: at most (N) predicate evaluations where  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

`bool pred(const Type &a);`

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *is\_partitioned* algorithm returns *bool*. The *is\_partitioned* algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise *is\_partitioned* returns false. If the range [first, last) contains less than two elements, the function is always true.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**>  
*hpx::parallel::util::detail::algorithm\_result\_t*<*ExPolicy*, bool> **is\_partitioned**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred)

Determines if the range [first, last) is partitioned. Executed according to the policy.

The predicate operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_partitioned* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (N) predicate evaluations where  $N = \text{distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). *Pred* must be *CopyConstructible* when using a parallel policy.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *is\_partitioned* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task\_execution\_policy* and returns *bool* otherwise. The *is\_partitioned* algorithm returns true if each element in the sequence for which *pred* returns true precedes those for which *pred* returns false. Otherwise *is\_partitioned* returns false. If the range `[first, last)` contains less than two elements, the function is always true.

## hpx::unique, hpx::unique\_copy

Defined in header `hpx/algorithm.hpp`<sup>642</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Pred = hpx::parallel::detail::equal_to, typename Proj =
hpx::identity>
FwdIter unique(FwdIter first, FwdIter last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range `[first, last)` and returns a past-the-end iterator for the new logical end of the range.

<sup>642</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

### Returns

The *unique* algorithm returns *FwdIter*. The *unique* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::equal_to,
typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type unique(ExPolicy &&policy, FwdIter first,
                                                                    FwdIter last, Pred &&pred =
                                                                    Pred(), Proj &&proj = Proj())
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range. Executed according to the policy.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

### Returns

The *unique* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *unique* algorithm returns the iterator to the new end of the range.

```
template<typename InIter, typename OutIter, typename Pred = hpx::parallel::detail::equal_to, typename Proj = hpx::identity>
```

```
OutIter unique_copy(InIter first, InIter last, OutIter dest, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique\_copy* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

#### Returns

The *unique\_copy* algorithm returns a returns *OutIter*. The *unique\_copy* algorithm returns the destination iterator to the end of the *dest* range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred =
hpx::parallel::detail::equal_to, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type unique_copy(ExPolicy &&policy,
FwdIter1 first, FwdIter1 last,
FwdIter2 dest, Pred &&pred
= Pred(), Proj &&proj =
Proj())
```

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied. Executed according to the policy.

The assignments in the parallel *unique\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first - 1* applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique\_copy* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

### Returns

The *unique\_copy* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *unique\_copy* algorithm returns the pair of the source iterator to *last*, and the destination iterator to the end of the *dest* range.

## hpx::adjacent\_find

Defined in header `hpx/algorithm.hpp`<sup>643</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename Pred = hpx::parallel::detail::equal_to>  
InIter adjacent_find(InIter first, InIter last, Pred &&pred = Pred())
```

Searches the range [first, last) for two consecutive identical elements.

---

**Note:** Complexity: Exactly the smaller of  $(result - first) + 1$  and  $(last - first) - 1$  application of the predicate where *result* is the value returned

---

### Template Parameters

- **InIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*.

### Returns

The *adjacent\_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

```
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::equal_to>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> adjacent_find(ExPolicy &&policy,  
FwdIter first, FwdIter  
last, Pred &&pred =  
Pred())
```

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate *pred*

---

<sup>643</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

The comparison operations in the parallel *adjacent\_find* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *adjacent\_find* invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *adjacent\_find* is available if the user decides to provide their algorithm their own binary predicate *pred*.

---

**Note:** Complexity: Exactly the smaller of  $(result - first) + 1$  and  $(last - first) - 1$  application of the predicate where *result* is the value returned

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent\_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

### Returns

The *adjacent\_find* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *adjacent\_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

## hpx::remove, hpx::remove\_if

Defined in header [hpx/algorithm.hpp](#)<sup>644</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename T = typename std::iterator_traits<FwdIter>::value_type>  
FwdIter remove(FwdIter first, FwdIter last, T const &value)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*.

The assignments in the parallel *remove* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the operator==().

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.

### Returns

The *remove* algorithm returns a *FwdIter*. The *remove* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter, typename T = typename  
std::iterator_traits<FwdIter>::value_type>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> remove(ExPolicy &&policy, FwdIter first,  
                                                                    FwdIter last, T const &value)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*. Executed according to the policy.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

<sup>644</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the operator==().

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.

#### Returns

The *remove* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *remove* algorithm returns the iterator to the new end of the range.

```
template<typename FwdIter, typename Pred>
FwdIter remove_if(FwdIter first, FwdIter last, Pred &&pred)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true.

The assignments in the parallel *remove\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_if* requires *Pred* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *remove\_if* algorithm returns a *FwdIter*. The *remove\_if* algorithm returns the iterator to the new end of the range.

```
template<typename ExPolicy, typename FwdIter, typename Pred>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> remove_if(ExPolicy &&policy, FwdIter  
first, FwdIter last, Pred  
&&pred)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true. Executed according to the policy.

The assignments in the parallel *remove\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove\_if* requires *Pred* to meet the requirements of *Copy-Constructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *remove\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *remove\_if* algorithm returns the iterator to the new end of the range.

## hpx::make\_heap

Defined in header `hpx/algorithm.hpp`<sup>645</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename RndIter, typename Comp>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> make_heap(ExPolicy &&policy, RndIter first,
                                                                    RndIter last, Comp &&comp)
```

Constructs a *max heap* in the range [first, last). Executed according to the policy.

The predicate operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *sequential\_execution\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *parallel\_execution\_policy* or *parallel\_task\_execution\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (3\*N) comparisons where *N* = distance(first, last).

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

<sup>645</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **Comp** – Comparison function object (i.e. an object that satisfies the requirements of Compare) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

```
bool cmp(const Type1 &a, const Type2 &b);
```

While the signature does not need to have const &, the function must not modify the objects passed to it and must be able to accept all values of type (possibly *const*) *Type1* and *Type2* regardless of value category (thus, *Type1* & is not allowed, nor is *Type1* unless for *Type1* a move is equivalent to a copy. The types *Type1* and *Type2* must be such that an object of type *RandomIt* can be dereferenced and then implicitly converted to both of them.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```
bool comp(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *make\_heap* algorithm returns a *hpx::future<void>* if the execution policy is of type *task\_execution\_policy* and returns *void* otherwise.

```
template<typename ExPolicy, typename RndIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> make_heap(ExPolicy &&policy, RndIter first,
                                                                    RndIter last)
```

Constructs a *max heap* in the range [first, last). Uses the operator < for comparisons. Executed according to the policy.

The predicate operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *sequential\_execution\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make\_heap* algorithm invoked with an execution policy object of type *parallel\_execution\_policy* or *parallel\_task\_execution\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (3\*N) comparisons where *N* = distance(first, last).

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

#### Returns

The *make\_heap* algorithm returns a *hpx::future<void>* if the execution policy is of type *task\_execution\_policy* and returns *void* otherwise.

```
template<typename RndIter, typename Comp>
void make_heap(RndIter first, RndIter last, Comp &&comp)
```

Constructs a *max heap* in the range [first, last).

---

**Note:** Complexity: at most (3\*N) comparisons where *N* = distance(first, last).

---

#### Template Parameters

- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.
- **Comp** – Comparison function object (i.e. an object that satisfies the requirements of Compare) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

```
bool cmp(const Type1 &a, const Type2 &b);
```

While the signature does not need to have const &, the function must not modify the objects passed to it and must be able to accept all values of type (possibly *const*) *Type1* and *Type2* regardless of value category (thus, *Type1* & is not allowed, nor is *Type1* unless for *Type1* a move is equivalent to a copy. The types *Type1* and *Type2* must be such that an object of type *RandomIt* can be dereferenced and then implicitly converted to both of them.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```
bool comp(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *make\_heap* algorithm returns a *void*.

```
template<typename RndIter>
void make_heap(RndIter first, RndIter last)
    Constructs a max heap in the range [first, last).
```

---

**Note:** Complexity: at most  $(3*N)$  comparisons where  $N = \text{distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

**RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

#### Returns

The *make\_heap* algorithm returns a *void*.

## hpx::experimental::reduction\_max

Defined in header [hpx/algorithm.hpp](#)<sup>646</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

### Functions

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, hpx::parallel::detail::max_of<T>> reduction_max(T
                                                                                                     &var)
```

The function template *reduction\_max* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses `std::max_of{ }` as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction\_max* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the `std::max_of{ }` operation until a single value remains, which is then assigned back to the live-out object.

---

<sup>646</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

$T$  shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

---

#### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

#### Parameters

- **var** – [in,out] The live-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

#### Returns

This returns a reduction object of unspecified type having a value type of  $T$ . When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of *identity*, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, hpx::parallel::detail::max_of<T>> reduction_max(T
                                                                    &var,
                                                                    T
                                                                    const
                                                                    &iden-
                                                                    tity)
```

## hpx::for\_each, hpx::for\_each\_n

Defined in header `hpx/algorithm.hpp`<sup>647</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

### Functions

```
template<typename InIter, typename F>
F for_each(InIter first, InIter last, F &&f)
```

Applies  $f$  to the result of dereferencing every iterator in the range  $[first, last)$ .

If  $f$  returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator,  $f$  may apply non-constant functions through the dereferenced iterator.

---

**Note:** Complexity: Applies  $f$  exactly  $last - first$  times.

---

<sup>647</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

### Template Parameters

- **InIter** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). **F** must meet requirements of *MoveConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

`<ignored> pred(const Type &a);`

The signature does not need to have `const&`. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

*f*.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, void> for_each(ExPolicy &&policy, FwdIter first, FwdIter last, F
&&f)
```

Applies *f* to the result of dereferencing every iterator in the range [first, last). Executed according to the policy.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for\_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Applies *f* exactly *last - first* times.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *for\_each* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `void` otherwise.

```
template<typename InIter, typename Size, typename F>
InIter for_each_n(InIter first, Size count, F &&f)
```

Applies *f* to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

---

**Note:** Complexity: Applies *f* exactly *count* times.

---

#### Template Parameters

- **InIter** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **F** – The type of the function/function object to use (deduced). *F* must meet requirements of *MoveConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

`<ignored> pred(const Type &a);`

The signature does not need to have `const&`. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

*first + count* for non-negative values of *count* and *first* for negative values.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result_t<ExPolicy, FwdIter> for_each_n(ExPolicy &&policy, FwdIter first, Size
count, F &&f)
```

Applies *f* to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1. Executed according to the policy.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for\_each\_n* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Applies *f* exactly *count* times.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for\_each\_n* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *for\_each\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. It returns *first* + *count* for non-negative values of *count* and *first* for negative values.

## hpx::transform

Defined in header `hpx/algorithm.hpp`<sup>648</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter1, typename FwdIter2, typename F>
FwdIter2 transform(FwdIter1 first, FwdIter1 last, FwdIter2 dest, F &&f)
```

Applies the given function *f* to the range [first, last) and stores the result in another range, beginning at dest.

---

**Note:** Complexity: Exactly *last* - *first* applications of *f*

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

<sup>648</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *Ret* must be such that an object of type *FwdIter2* can be dereferenced and assigned a value of type *Ret*.

### Returns

The *transform* algorithm returns a *FwdIter2*. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename F>  
parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> transform(ExPolicy &&policy, FwdIter1 first,  
                                                                    FwdIter1 last, FwdIter2 dest, F  
                                                                    &&f)
```

Applies the given function *f* to the range [first, last) and stores the result in another range, beginning at dest. Executed according to the policy.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *last - first* applications of *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type &a);
```

The signature does not need to have `const&`. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *Ret* must be such that an object of type *FwdIter2* can be dereferenced and assigned a value of type *Ret*.

### Returns

The *transform* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename F>
FwdIter3 transform(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter3 dest, F &&f)
```

Applies the given function *f* to pairs of elements from two ranges: one defined by [first1, last1) and the other beginning at first2, and stores the result in another range, beginning at dest.

---

**Note:** Complexity: Exactly *last - first* applications of *f*

---

### Template Parameters

- **FwdIter1** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively. The type *Ret* must be such that an object of type *FwdIter3* can be dereferenced and assigned a value of type *Ret*.

### Returns

The *transform* algorithm returns a *FwdIter3*. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename F>  
parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter3> transform(ExPolicy &&policy, FwdIter1  
first1, FwdIter1 last1, FwdIter2  
first2, FwdIter3 dest, F &&f)
```

Applies the given function *f* to pairs of elements from two ranges: one defined by [first1, last1) and the other beginning at first2, and stores the result in another range, beginning at dest. Executed according to the policy.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *last - first* applications of *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **FwdIter1** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.

- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively. The type *Ret* must be such that an object of type *FwdIter3* can be dereferenced and assigned a value of type *Ret*.

### Returns

The *transform* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter3* otherwise. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

## hpx::uninitialized\_move, hpx::uninitialized\_move\_n

Defined in header `hpx/algorithm.hpp`<sup>649</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename FwdIter>
FwdIter uninitialized_move(InIter first, InIter last, FwdIter dest)
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

---

<sup>649</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

#### Returns

The *uninitialized\_move* algorithm returns *FwdIter*. The *uninitialized\_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> uninitialized_move(ExPolicy
                                                                                      &&policy,
                                                                                      FwdIter1 first,
                                                                                      FwdIter1 last,
                                                                                      FwdIter2 dest)
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state. Executed according to the policy.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_move* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

#### Returns

The *uninitialized\_move* algorithm returns a *hpx::future<FwdIter2>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```
template<typename InIter, typename Size, typename FwdIter>
```

`std::pair<InIter, FwdIter> uninitialized_move_n(InIter first, Size count, FwdIter dest)`

Moves the elements in the range `[first, first + count)`, starting from `first` and proceeding to `first + count - 1`, to another range beginning at `dest`. If an exception is thrown during the initialization, some objects in `[first, first + count)` are left in a valid but unspecified state.

---

**Note:** Complexity: Performs exactly *count* movements, if *count* > 0, no move operations otherwise.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

#### Returns

The *uninitialized\_move\_n* algorithm returns a returns `std::pair<InIter, FwdIter>`. The *uninitialized\_move\_n* algorithm returns A pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, std::pair<FwdIter1, FwdIter2>>::type uninitialized_move_n(ExPolicy
&&pol-
icy,
FwdIter1
first,
Size
count,
FwdIter2
dest)
```

Moves the elements in the range `[first, first + count)`, starting from `first` and proceeding to `first + count - 1`, to another range beginning at `dest`. If an exception is thrown during the initialization, some objects in `[first, first + count)` are left in a valid but unspecified state. Executed according to the policy.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_move\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* movements, if *count* > 0, no move operations otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

### Returns

The *uninitialized\_move\_n* algorithm returns a `hpx::future<std::pair<FwdIter1,FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `std::pair<FwdIter1,FwdIter2>` otherwise. The *uninitialized\_move\_n* algorithm returns A pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

## hpx::partial\_sort

Defined in header [hpx/algorithm.hpp](#)<sup>650</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename RandIter, typename Comp = hpx::parallel::detail::less>  
RandIter partial_sort(RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

---

**Note:** Complexity: Approximately (last - first) \* log(middle - first) comparisons.

---

### Template Parameters

- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

---

<sup>650</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to `detail::less`.

#### Returns

The *partial\_sort* algorithm returns a *RandIter* that refers to *last*.

```
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>
parallel::util::detail::algorithm_result_t<ExPolicy, RandIter> partial_sort(ExPolicy &&policy, RandIter
                                                                    first, RandIter middle, RandIter
                                                                    last, Comp &&comp =
                                                                    Comp())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

---

**Note:** Complexity: Approximately  $(last - first) * \log(middle - first)$  comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to `detail::less`.

**Returns**

The *partial\_sort* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandIter* otherwise. The iterator returned refers to *last*.

**hpx::search, hpx::search\_n**

Defined in header [hpx/algorithm.hpp](#)<sup>651</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

```
template<typename FwdIter, typename FwdIter2, typename Pred = parallel::detail::equal_to>
FwdIter search(FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most ( $S \cdot N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

---

<sup>651</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

### Returns

The *search* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

```
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred =
parallel::detail::equal_to>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> search(ExPolicy &&policy, FwdIter first,
                                                                    FwdIter last, FwdIter2 s_first,
                                                                    FwdIter2 s_last, Pred &&op =
                                                                    Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(S \cdot N)$  comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

#### Returns

The *search* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

```
template<typename FwdIter, typename Searcher>  
FwdIter search(FwdIter first, FwdIter last, Searcher &&searcher)
```

Searches the range `[first, last)` using a searcher object.

#### Template Parameters

- **FwdIter** – The type of the source iterators (deduced). This iterator type must meet the requirements of a forward iterator.
- **Searcher** – A callable searcher object meeting the C++ Searcher requirements (e.g. `std::boyer_moore_searcher`).

#### Parameters

- **first** – Refers to the beginning of the sequence to search.
- **last** – Refers to the end of the sequence to search.
- **searcher** – A callable object performing the search.

#### Returns

An iterator to the beginning of the found subsequence, or *last* if no subsequence is found.

```
template<typename ExPolicy, typename FwdIter, typename Searcher>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> search(ExPolicy &&policy, FwdIter first,  
                                                                           FwdIter last, Searcher  
                                                                           &&searcher)
```

Searches the range `[first, last)` using a searcher object. Executed according to the policy.

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced).

- **FwdIter** – The type of the source iterators (deduced).
- **Searcher** – A callable searcher object meeting the C++ Searcher requirements.

#### Parameters

- **policy** – The execution policy to use.
- **first** – Refers to the beginning of the sequence to search.
- **last** – Refers to the end of the sequence to search.
- **searcher** – A callable object performing the search.

#### Returns

The algorithm returns a `hpx::future<FwdIter>` if the execution policy is a task policy, or `FwdIter` otherwise.

```
template<typename FwdIter, typename FwdIter2, typename Pred = parallel::detail::equal_to>
FwdIter search_n(FwdIter first, std::size_t count, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(S \cdot N)$  comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{count}$ .

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `search_n` requires `Pred` to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *search\_n* algorithm returns *FwdIter*. The *search\_n* algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count)`, *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

```
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred =  
parallel::detail::equal_to>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> search_n(ExPolicy &&policy, FwdIter  
first, std::size_t count, FwdIter2  
s_first, FwdIter2 s_last, Pred  
&&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel *search\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(S*N)$  comparisons where  $S$  = distance(`s_first, s_last`) and  $N$  = count.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search\_n* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *search\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *search\_n* algorithm returns an iterator to the beginning of the last subsequence [s\_first, s\_last) in range [first, first+count). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, first+count), *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

## hpx::set\_difference

Defined in header [hpx/algorithm.hpp](#)<sup>652</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename
Pred = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter3> set_difference(ExPolicy &&policy,
                                          FwdIter1 first1,
                                          FwdIter1 last1,
                                          FwdIter2 first2,
                                          FwdIter2 last2,
                                          FwdIter3 dest, Pred
                                          &&op = Pred())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

Equivalent elements are treated individually, that is, if some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly `std::max(m-n, 0)` times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

<sup>652</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

### Returns

The *set\_difference* algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter3* otherwise. The

*set\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred =
    hpx::parallel::detail::less>
FwdIter3 set_difference(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest,
    Pred &&op = Pred())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

Equivalent elements are treated individually, that is, if some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly  $\text{std::max}(m-n, 0)$  times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

#### Returns

The *set\_difference* algorithm returns a *FwdIter3*. The *set\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

### hpx::transform\_exclusive\_scan

Defined in header `hpx/algorithm.hpp`<sup>653</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

#### Functions

```
template<typename InIter, typename OutIter, typename BinOp, typename UnOp, typename T = typename
std::iterator_traits<InIter>::value_type>
OutIter transform_exclusive_scan(InIter first, InIter last, OutIter dest, T init, BinOp &&binary_op,
                                UnOp &&unary_op)
```

Transforms each element in the range `[first, last)` with *unary\_op*, then computes an exclusive prefix sum operation using *binary\_op* over the resulting range, with *init* as the initial value, and writes the results to the range beginning at *dest*. “exclusive” means that the *i*-th input element is not included in the *i*-th sum. Formally, assigns through each iterator *i* in `[dest, d_first + (last - first))` the value of the generalized noncommutative sum of *init*, *unary\_op*(*\*j*)... for every *j* in `[first, first + (i - d_first))` over *binary\_op*, where generalized noncommutative sum *GNSUM*(*op*, *a1*, ..., *aN*) is defined as follows:

- if *N*=1, *a1*
- if *N* > 1, *op*(*GNSUM*(*op*, *a1*, ..., *aK*), *GNSUM*(*op*, *aM*, ..., *aN*)) for any *K* where  $1 < K+1 = M \leq N$  In other words, the summation operations may be performed in arbitrary order, and the behavior is nondeterministic if *binary\_op* is not associative.

The reduce operations in the parallel *transform\_exclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *unary\_op* nor *binary\_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges `[first,last)` or `[result,result + (last - first))`.

The behavior of *transform\_exclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of each of *binary\_op* and *unary\_op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a1*, ..., *aN*) is defined as:

- *a1* when *N* is 1

---

<sup>653</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of *binary\_op*.
- **UnOp** – The type of *unary\_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **binary\_op** – Binary *FunctionObject* that will be applied to the result of *unary\_op*, the results of other *binary\_op*, and *init*.
- **unary\_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary\_op*.

### Returns

The *transform\_exclusive\_scan* algorithm returns a returns *OutIter*. The *transform\_exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename BinOp, typename UnOp,
        typename T = typename std::iterator_traits<FwdIter1>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_exclusive_scan(ExPolicy
                                                                                               &&policy,
                                                                                               FwdIter1
                                                                                               first,
                                                                                               FwdIter1
                                                                                               last,
                                                                                               FwdIter2
                                                                                               dest, T init,
                                                                                               BinOp
                                                                                               &&bi-
                                                                                               nary_op,
                                                                                               UnOp
                                                                                               &&unary_op)
```

Assigns through each iterator *i* in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), ..., conv(*(first + (i - result) - 1))`). Executed according to the policy.

The reduce operations in the parallel *transform\_exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *unary\_op* nor *binary\_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The behavior of *transform\_exclusive\_scan* may be non-deterministic for a non-associative predicate.

---

**Note:** Complexity:  $O(last - first)$  applications of each of *binary\_op* and *unary\_op*.

---

---

**Note:** *GENERALIZED\_NONCOMMUTATIVE\_SUM*(*op*, *a1*, ..., *aN*) is defined as:

- *a1* when *N* is 1
  - *op*(*GENERALIZED\_NONCOMMUTATIVE\_SUM*(*op*, *a1*, ..., *aK*), *GENERALIZED\_NONCOMMUTATIVE\_SUM*(*op*, *aM*, ..., *aN*) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of *binary\_op*.
- **UnOp** – The type of *unary\_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **binary\_op** – Binary *FunctionObject* that will be applied in to the result of *unary\_op*, the results of other *binary\_op*, and *init*.
- **unary\_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary\_op*.

**Returns**

The *transform\_exclusive\_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *transform\_exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**hpx::experimental::induction**

Defined in header [hpx/algorithm.hpp](#)<sup>654</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

**Functions**

template<typename **T**>

constexpr *hpx::parallel::detail::induction\_stride\_helper<T>* **induction**(*T* &&value, *std::size\_t* stride)

The function template returns an induction object of unspecified type having a value type and encapsulating an initial *value* of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence *S* computes an induction value from an induction variable and ordinal position *p* within *S* by the formula  $i + p * \text{stride}$  if a stride was specified or  $i + p$  otherwise. This induction value is passed to the element access function.

If the *value* argument to *induction* is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of  $i + n * \text{stride}$  to the live-out object upon return, where *n* is the number of elements in the input range.

**Template Parameters**

**T** – The value type to be used by the induction object.

**Parameters**

- **value** – [in] The initial value to use for the induction object
- **stride** – [in] The (optional) stride to use for the induction object (default: 1)

**Returns**

This returns an induction object with value type *T*, initial *value*, and (if specified) *stride*. If *T* is a lvalue of non-const type, *value* is used as the live-out object for the induction object; otherwise there is no live-out object.

template<typename **T**>

constexpr *hpx::parallel::detail::induction\_helper<T>* **induction**(*T* &&value)

<sup>654</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

**hpx::uninitialized\_default\_construct, hpx::uninitialized\_default\_construct\_n**

Defined in header [hpx/algorithm.hpp](#)<sup>655</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

```
template<typename FwdIter>  
void uninitialized_default_construct(FwdIter first, FwdIter last)
```

Constructs objects of type `typename iterator_traits<ForwardIt> ::value_type` in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

**FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The *uninitialized\_default\_construct* algorithm returns nothing

```
template<typename ExPolicy, typename FwdIter>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> uninitialized_default_construct(ExPolicy  
                                                                                          &&policy,  
                                                                                          FwdIter  
                                                                                          first,  
                                                                                          FwdIter  
                                                                                          last)
```

Constructs objects of type `typename iterator_traits<ForwardIt> ::value_type` in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

<sup>655</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

The assignments in the parallel *uninitialized\_default\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

#### Returns

The *uninitialized\_default\_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

```
template<typename FwdIter, typename Size>
FwdIter uninitialized_default_construct_n(FwdIter first, Size count)
```

Constructs objects of type `typename iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range `[first, first + count)` by default-initialization. If an exception is thrown during the initialization, the function has no effects.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

#### Returns

The *uninitialized\_default\_construct\_n* algorithm returns a *FwdIter*. The *uninitialized\_default\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Size>
```

*hpx::parallel::util::detail::algorithm\_result\_t<ExPolicy, FwdIter>* **uninitialized\_default\_construct\_n**(*ExPolicy* &&*policy*, *FwdIter* *first*, *Size* *count*)

Constructs objects of type *typename iterator\_traits<ForwardIt> ::value\_type* in the uninitialized storage designated by the range [*first*, *first* + *count*) by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized\_default\_construct\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_default\_construct\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

#### Returns

The *uninitialized\_default\_construct\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_default\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

**hpx::min\_element, hpx::max\_element, hpx::minmax\_element**

Defined in header `hpx/algorithm.hpp`<sup>656</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

```
template<typename FwdIter, typename F = hpx::parallel::detail::less>
FwdIter min_element(FwdIter first, FwdIter last, F &&f)
```

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

**Returns**

The *min\_element* algorithm returns *FwdIter*. The *min\_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> min_element(ExPolicy &&policy, FwdIter
first, FwdIter last, F &&f)
```

---

<sup>656</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

Finds the smallest element in the range `[first, last)` using the given comparison function *f*. Executed according to the policy.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *min\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *min\_element* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

### Returns

The *min\_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *min\_element* algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename FwdIter, typename F = hpx::parallel::detail::less>  
FwdIter max_element(FwdIter first, FwdIter last, F &&f)
```

Finds the largest element in the range `[first, last)` using the given comparison function *f*.

The comparisons in the parallel *min\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if left argument is less than the right element. This argument is optional and defaults to `std::less`. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

### Returns

The *max\_element* algorithm returns *FwdIter*. The *max\_element* algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns `last` if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type max_element(ExPolicy &&policy,
                                                                                   FwdIter first, FwdIter
                                                                                   last, F &&f)
```

Removes all elements satisfying specific criteria from the range Finds the largest element in the range `[first, last)` using the given comparison function *f*. Executed according to the policy.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *max\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly  $\max(N-1, 0)$  comparisons, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *max\_element* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if left argument is less than the right element. This argument is optional and defaults to `std::less`. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

#### Returns

The *max\_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *max\_element* algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns `last` if the range is empty.

```
template<typename FwdIter, typename F = hpx::parallel::detail::less>  
minmax_element_result<FwdIter> minmax_element(FwdIter first, FwdIter last, F &&f)
```

Finds the largest element in the range `[first, last)` using the given comparison function *f*.

The comparisons in the parallel *minmax\_element* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $\max(\text{floor}(3/2*(N-1)), 0)$  applications of the predicate, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

### Returns

The *minmax\_element* algorithm returns a *minmax\_element\_result*<*FwdIter*>. The *minmax\_element* algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns *minmax\_element\_result*<*FwdIter*>{*first*,*first*} if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```
template<typename ExPolicy, typename FwdIter, typename F = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, minmax_element_result<FwdIter>> minmax_element(ExPolicy
&&policy,
FwdIter
first,
FwdIter
last,
F
&&f)
```

Finds the largest element in the range [*first*, *last*) using the given comparison function *f*.

The comparisons in the parallel *minmax\_element* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *minmax\_element* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\max(\text{floor}(3/2*(N-1)), 0)$  applications of the predicate, where  $N = \text{std::distance}(\text{first}, \text{last})$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *minmax\_element* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

### Returns

The *minmax\_element* algorithm returns a `hpx::future<minmax_element_result<FwdIter>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *minmax\_element\_result<FwdIter>* otherwise. The *minmax\_element* algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns `std::make_pair(first,first)` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

## hpx::copy, hpx::copy\_n, hpx::copy\_if

Defined in header `hpx/algorithm.hpp`<sup>657</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> copy(ExPolicy &&policy, FwdIter1 first,
                                                                    FwdIter1 last, FwdIter2 dest)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Executed according to the policy.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

<sup>657</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

### Returns

The *copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2>
FwdIter2 copy(FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

### Returns

The *copy* algorithm returns a *FwdIter2*. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> copy_n(ExPolicy &&policy, FwdIter1
                                                                    first, Size count, FwdIter2 dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. Executed according to the policy.

The assignments in the parallel *copy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

#### Returns

The *copy\_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *copy\_n* algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

```
template<typename FwdIter1, typename Size, typename FwdIter2>
FwdIter2 copy_n(FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest.

---

**Note:** Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

#### Returns

The *copy\_n* algorithm returns a *FwdIter2* . The *copy\_n* algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> copy_if(ExPolicy &&policy, FwdIter1
                                                                    first, FwdIter1 last, FwdIter2
                                                                    dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved. Executed according to the policy.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *copy\_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *copy\_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename Pred>  
FwdIter2 copy_if(FwdIter1 first, FwdIter1 last, FwdIter2 dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy\_if* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *copy\_if* algorithm returns a *FwdIter2*. The *copy\_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

## hpx::swap\_ranges

Defined in header `hpx/algorithm.hpp`<sup>658</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter1, typename FwdIter2>
FwdIter2 swap_ranges(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2)
```

Exchanges elements between range [first1, last1) and another range starting at first2.

The swap operations in the parallel *swap\_ranges* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first1* and *last1*.

---

### Template Parameters

- **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

### Returns

The *swap\_ranges* algorithm returns *FwdIter2*. The *swap\_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
```

---

<sup>658</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

```
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> swap_ranges(ExPolicy &&policy,
                                                                              FwdIter1 first1, FwdIter1
                                                                              last1, FwdIter2 first2)
```

Exchanges elements between range [first1, last1) and another range starting at *first2*. Executed according to the policy.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The swap operations in the parallel *swap\_ranges* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first1* and *last1*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the swap operations.
- **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

### Returns

The *swap\_ranges* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *swap\_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

## hpx::mismatch

Defined in header [hpx/algorithm.hpp](#)<sup>659</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

---

<sup>659</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy
&&pol-
icy,
FwdIter1
first1,
FwdIter1
last1,
FwdIter2
first2,
FwdIter2
last2,
Pred
&&op)
```

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator==* are made.

---

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range [first1,last1), \**i* mismatches \*(first2 + (i - first1)). This overload of *mismatch* uses *operator==* to determine if two elements are mismatch.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1,FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `std::pair<FwdIter1,FwdIter2>` otherwise. If no mismatches are found when the comparison reaches `last1` or `last2`, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy
                                                                                                     &&pol-
                                                                                                     icy,
                                                                                                     FwdIter1
                                                                                                     first1,
                                                                                                     FwdIter1
                                                                                                     last1,
                                                                                                     FwdIter2
                                                                                                     first2,
                                                                                                     FwdIter2
                                                                                                     last2)
```

Returns the first mismatching pair of elements from two ranges: one defined by [`first1`, `last1`) and another defined by [`first2`, `last2`). If `last2` is not provided, it denotes `first2 + (last1 - first1)`. Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of `operator==`. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and  $(\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})$  then no

applications of *operator==* are made.

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range  $[first1, last1)$ , *\*i* mismatches  $*(first2 + (i - first1))$ . This overload of mismatch uses *operator==* to determine if two elements are mismatch.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

### Returns

The *mismatch* algorithm returns a *hpx::future<std::pair<FwdIter1, FwdIter2>>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *std::pair<FwdIter1, FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy
&&pol-
icy,
FwdIter1
first1,
FwdIter1
last1,
FwdIter2
first2,
Pred
&&op)
```

Returns the first mismatching pair of elements from two ranges: one defined by  $[first1, last1)$  and another defined by  $[first2, last2)$ . If last2 is not provided, it denotes  $first2 + (last1 - first1)$ . Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $\text{last1} - \text{first1}$  applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and  $(\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})$  then no applications of the predicate *op* or *operator==* are made.

---

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range  $[\text{first1}, \text{last1})$ , *\*i* mismatches  $*(\text{first2} + (i - \text{first1}))$ . This overload of *mismatch* uses *operator==* to determine if two elements are mismatch.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the

execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy
                                                                                               &&pol-
                                                                                               icy,
                                                                                               FwdIter1
                                                                                               first1,
                                                                                               FwdIter1
                                                                                               last1,
                                                                                               FwdIter2
                                                                                               first2)
```

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last1 - first1 applications of *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator==* are made.

---

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range [first1,last1), *\*i* mismatches *\*(first2 + (i - first1))*. This overload of *mismatch* uses *operator==* to determine if two elements are mismatch.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal\_to<>*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

#### Returns

The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1,FwdIter2>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `std::pair<FwdIter1,FwdIter2>` otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename FwdIter1, typename FwdIter2, typename Pred>
std::pair<FwdIter1, FwdIter2> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2,
                                     Pred &&op)
```

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and  $(\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})$  then no applications of the predicate *op* or *operator==* are made.

---

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range [first1,last1), *\*i* mismatches  $*(\text{first2} + (i - \text{first1}))$ . This overload of *mismatch* uses *operator==* to determine if two elements are mismatch.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

#### Returns

The *mismatch* algorithm returns a `std::pair<FwdIter1,FwdIter2>`. If no mismatches are found when the comparison reaches `last1` or `last2`, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename FwdIter1, typename FwdIter2>
std::pair<FwdIter1, FwdIter2> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2,last2)`. If `last2` is not provided, it denotes `first2 + (last1 - first1)`.

---

**Note:** Complexity: At most `min(last1 - first1, last2 - first2)` applications of `operator==`. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and `(last1 - first1) != (last2 - first2)` then no applications of `operator==` are made.

---

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range `[first1,last1)`, `*i` mismatches `*(first2 + (i - first1))`. This overload of *mismatch* uses `operator==` to determine if two elements are mismatch.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

#### Returns

The *mismatch* algorithm returns a `std::pair<FwdIter1,FwdIter2>`. If no mismatches are found when the comparison reaches `last1` or `last2`, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename FwdIter1, typename FwdIter2, typename Pred>
std::pair<FwdIter1, FwdIter2> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, Pred &&op)
```

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2, last2). If last2 is not provided, it denotes first2 + (last1 - first1).

---

**Note:** Complexity: At most last1 - first1 applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator==* are made.

---

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range [first1, last1), *\*i* mismatches *\*(first2 + (i - first1))*. This overload of *mismatch* uses *operator==* to determine if two elements are mismatch.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *mismatch* algorithm returns a `std::pair<FwdIter1, FwdIter2>`. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename FwdIter1, typename FwdIter2>
std::pair<FwdIter1, FwdIter2> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2)
```

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2, last2). If last2 is not provided, it denotes first2 + (last1 - first1).

---

**Note:** Complexity: At most  $\text{last1} - \text{first1}$  applications of `operator==`. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and  $(\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})$  then no applications of `operator==` are made.

---

---

**Note:** The two ranges are considered mismatch if, for every iterator *i* in the range  $[\text{first1}, \text{last1})$ , *\*i* mismatches  $*(\text{first2} + (i - \text{first1}))$ . This overload of `mismatch` uses `operator==` to determine if two elements are mismatch.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

### Returns

The `mismatch` algorithm returns a `std::pair<FwdIter1, FwdIter2>`. If no mismatches are found when the comparison reaches `last1` or `last2`, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

## `hpx::find`, `hpx::find_if`, `hpx::find_if_not`, `hpx::find_end`, `hpx::find_first_of`

Defined in header `hpx/algorithm.hpp`<sup>660</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter> find(ExPolicy &&policy, FwdIter first, FwdIter last, T
                                                         const &val)
```

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the operator==().

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to find (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to

### Returns

The *find* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename InIter, typename T>
InIter find(InIter first, InIter last, T const &val)
```

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

---

**Note:** Complexity: At most last - first applications of the operator==().

---

### Template Parameters

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.

- **T** – The type of the value to find (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to

#### Returns

The *find* algorithm returns a *InIter*. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, FwdIter> find_if(ExPolicy &&policy, FwdIter first, FwdIter last,
                                                             F &&f)
```

Returns the first element in the range [first, last) for which predicate *f* returns true. Executed according to the policy.

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *find\_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if* algorithm returns the first element in the range `[first,last)` that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename InIter, typename F>  
InIter find_if(InIter first, InIter last, F &&f)
```

Returns the first element in the range `[first, last)` for which predicate *f* returns true.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *find\_if* algorithm returns a *InIter*. The *find\_if* algorithm returns the first element in the range `[first,last)` that satisfies the predicate *f*. If no such element exists that satisfies the predicate *f*, the algorithm returns *last*.

```
template<typename ExPolicy, typename FwdIter, typename F>  
util::detail::algorithm_result_t<ExPolicy, FwdIter> find_if_not(ExPolicy &&policy, FwdIter first, FwdIter  
                                                                last, F &&f)
```

Returns the first element in the range `[first, last)` for which predicate *f* returns false. Executed according to the policy.

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_if\_not* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *find\_if\_not* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_if\_not* algorithm returns the first element in the range `[first, last)` that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate *f*, the algorithm returns *last*.

```
template<typename FwdIter, typename F>
FwdIter find_if_not(FwdIter first, FwdIter last, F &&f)
```

Returns the first element in the range `[first, last)` for which predicate *f* returns false.

---

**Note:** Complexity: At most last - first applications of the predicate.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *find\_if\_not* algorithm returns a *FwdIter*. The *find\_if\_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate *f*, the algorithm returns *last*.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_end(ExPolicy &&policy, FwdIter1 first1, FwdIter1
                                                             last1, FwdIter2 first2, FwdIter2 last2, Pred
                                                             &&op = Pred())
```

Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate *op* to compare elements. Executed according to the policy.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find\_end* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most  $S \cdot (N - S + 1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::equal_to<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

#### Returns

The *find\_end* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence `[first2, last2)` in range `[first, last)`. If the length of the subsequence `[first2, last2)` is greater than the length of the range `[first1, last1)`, *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_end(ExPolicy &&policy, FwdIter1 first1, FwdIter1
                                                             last1, FwdIter2 first2, FwdIter2 last2)
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first, last)`. Elements are compared using *operator==*. Executed according to the policy.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_end* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $S \cdot (N - S + 1)$  comparisons where  $S$  = distance(*first2*, *last2*) and  $N$  = distance(*first1*, *last1*).

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.

#### Returns

The *find\_end* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>  
FwdIter1 find_end(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate *op* to compare elements.

This overload of *find\_end* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most  $S \cdot (N - S + 1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

### Returns

The *find\_end* algorithm returns a *FwdIter1*. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename FwdIter1, typename FwdIter2>
FwdIter1 find_end(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns the last subsequence of elements [first2, last2) found in the range [first, last). Elements are compared using *operator==*.

---

**Note:** Complexity: at most  $S \cdot (N - S + 1)$  comparisons where  $S = \text{distance}(\text{first2}, \text{last2})$  and  $N = \text{distance}(\text{first1}, \text{last1})$ .

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.

### Returns

The *find\_end* algorithm returns a *FwdIter1*. The *find\_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_first_of(ExPolicy &&policy, FwdIter1 first,
                                                                    FwdIter1 last, FwdIter2 s_first,
                                                                    FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses binary predicate *op* to compare elements. Executed according to the policy.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find\_first\_of* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most ( $S \cdot N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

### Returns

The *find\_first\_of* algorithm returns a *hpx::future<FwdIter1>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter1* otherwise. The *find\_first\_of* algorithm returns an iterator to the first element in the range `[first, last)` that is equal to an element from the range `[s_first, s_last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_first_of(ExPolicy &&policy, FwdIter1 first,
                                                                    FwdIter1 last, FwdIter2 s_first,
                                                                    FwdIter2 s_last)
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Elements are compared using *operator==*. Executed according to the policy.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_first\_of* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(S \cdot N)$  comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

#### Returns

The *find\_first\_of* algorithm returns a *hpx::future<FwdIter1>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter1* otherwise. The *find\_first\_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s\_first, s\_last). If the length of the subsequence [s\_first, s\_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter1 find_first_of(FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op =
    Pred())
```

Searches the range [first, last) for any elements in the range [s\_first, s\_last). Uses binary predicate *op* to compare elements.

This overload of *find\_first\_of* is available if the user decides to provide the algorithm their own predicate *op*.

---

**Note:** Complexity: at most ( $S \cdot N$ ) comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

### Returns

The *find\_first\_of* algorithm returns a *FwdIter1*. The *find\_first\_of* algorithm returns an iterator to the first element in the range `[first, last)` that is equal to an element from the range `[s_first, s_last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

```
template<typename FwdIter1, typename FwdIter2>
FwdIter1 find_first_of(FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last)
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Elements are compared using *operator==*.

---

**Note:** Complexity: at most  $(S \cdot N)$  comparisons where  $S = \text{distance}(s\_first, s\_last)$  and  $N = \text{distance}(first, last)$ .

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s\_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s\_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

### Returns

The *find\_first\_of* algorithm returns a *FwdIter1*. The *find\_first\_of* algorithm returns an iterator to the first element in the range `[first, last)` that is equal to an element from the range `[s_first, s_last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

```
template<typename ExPolicy, typename BidIter, typename T>
util::detail::algorithm_result_t<ExPolicy, BidIter> find_last(ExPolicy &&policy, BidIter first, BidIter
                                                             last, T const &val)
```

Returns the last element in the range `[first, last)` that is equal to *val*. Executed according to the policy.

The comparison operations in the parallel *find\_last* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_last* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the operator `==`.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **T** – The type of the value to find (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **val** – The value to find.

#### Returns

The *find\_last* algorithm returns a *hpx::future<BidIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *BidIter* otherwise. The *find\_last* algorithm returns an iterator to the last element in the range `[first, last)` that is equal to *val*. If no such element is found, the function returns *last*.

```
template<typename InIter, typename T>  
InIter find_last(InIter first, InIter last, T const &val)
```

Returns the last element in the range `[first, last)` that is equal to *val*.

---

**Note:** Complexity: At most *last - first* applications of the operator `==`.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to find (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **val** – The value to find.

### Returns

The *find\_last* algorithm returns a *InIter*. The *find\_last* algorithm returns an iterator to the last element in the range [first, last) that is equal to *val*. If no such element is found, the function returns *last*.

```
template<typename ExPolicy, typename BidIter, typename F>
util::detail::algorithm_result_t<ExPolicy, BidIter> find_last_if(ExPolicy &&policy, BidIter first, BidIter
                                                                    last, F &&f)
```

Returns the last element in the range [first, last) for which predicate *f* returns true. Executed according to the policy.

The comparison operations in the parallel *find\_last\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_last\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **F** – The type of the function/predicate to use (deduced). Must be callable with the type of the elements in the range.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The predicate to check.

### Returns

The *find\_last\_if* algorithm returns a *hpx::future<BidIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *BidIter* otherwise. The *find\_last\_if* algorithm returns an iterator to the last element in the range [first, last) for which predicate *f* returns true. If no such element is found, the function returns *last*.

```
template<typename InIter, typename F>
InIter find_last_if(InIter first, InIter last, F &&f)
```

Returns the last element in the range [first, last) for which predicate *f* returns true.

---

**Note:** Complexity: At most *last - first* applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/predicate to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The predicate to check.

#### Returns

The *find\_last\_if* algorithm returns a *InIter*. The *find\_last\_if* algorithm returns an iterator to the last element in the range [first, last) for which predicate *f* returns true. If no such element is found, the function returns *last*.

```
template<typename ExPolicy, typename BidiIter, typename F>  
util::detail::algorithm_result_t<ExPolicy, BidiIter> find_last_if_not(ExPolicy &&policy, BidiIter first,  
                                                                    BidiIter last, F &&f)
```

Returns the last element in the range [first, last) for which predicate *f* returns false. Executed according to the policy.

The comparison operations in the parallel *find\_last\_if\_not* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find\_last\_if\_not* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidiIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **F** – The type of the function/predicate to use (deduced). Must be callable with the type of the elements in the range.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The predicate to check.

#### Returns

The *find\_last\_if\_not* algorithm returns a *hpx::future<BidIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *BidIter* otherwise. The *find\_last\_if\_not* algorithm returns an iterator to the last element in the range [first, last) for which predicate *f* returns false. If no such element is found, the function returns *last*.

```
template<typename InIter, typename F>
InIter find_last_if_not(InIter first, InIter last, F &&f)
```

Returns the last element in the range [first, last) for which predicate *f* returns false.

---

**Note:** Complexity: At most *last - first* applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/predicate to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The predicate to check.

#### Returns

The *find\_last\_if\_not* algorithm returns a *InIter*. The *find\_last\_if\_not* algorithm returns an iterator to the last element in the range [first, last) for which predicate *f* returns false. If no such element is found, the function returns *last*.

## hpx::experimental::reduction\_plus

Defined in header [hpx/algorithm.hpp](#)<sup>661</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

---

<sup>661</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::plus<T>> reduction_plus(T &var)
```

The function template *reduction\_plus* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses `std::plus{}` as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction\_plus* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the `std::plus{}` operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

---

### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

### Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

### Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::plus<T>> reduction_plus(T &var, T const
                                                                                      &identity)
```

## hpx::experimental::reduction\_min

Defined in header `hpx/algorithm.hpp`<sup>662</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

---

<sup>662</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

namespace **experimental**

Top-level namespace.

## Functions

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, hpx::parallel::detail::min_of<T>> reduction_min(T
                                                                    &var)
```

The function template *reduction\_min* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses `std::min_of{ }` as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction\_min* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the `std::min_of{ }` operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

---

### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

### Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

### Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, hpx::parallel::detail::min_of<T>> reduction_min(T
                                                                    &var,
                                                                    T
                                                                    const
                                                                    &iden-
                                                                    tity)
```

## hpx::rotate, hpx::rotate\_copy

Defined in header [hpx/algorithm.hpp](#)<sup>663</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

template<typename **FwdIter**>

*FwdIter* **rotate**(*FwdIter* first, *FwdIter* new\_first, *FwdIter* last)

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element new\_first becomes the first element of the new range and new\_first - 1 becomes the last element.

The assignments in the parallel *rotate* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

### Template Parameters

**FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

### Returns

The *rotate* algorithm returns a *FwdIter*. The *rotate* algorithm returns the iterator to the new location of the element pointed by first, equal to first + (last - new\_first).

template<typename **ExPolicy**, typename **FwdIter**>

*hpx::parallel::util::detail::algorithm\_result\_t*<*ExPolicy*, *FwdIter*> **rotate**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* new\_first, *FwdIter* last)

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element new\_first becomes the first element of the new range and new\_first - 1 becomes the last element. Executed according to the policy.

---

<sup>663</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

### Returns

The *rotate* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *rotate* algorithm returns the iterator equal to *first* + (*last* - *new\_first*).

```
template<typename FwdIter, typename OutIter>
OutIter rotate_copy(FwdIter first, FwdIter new_first, FwdIter last, OutIter dest_first)
```

Copies the elements from the range [*first*, *last*), to another range beginning at *dest\_first* in such a way, that the element *new\_first* becomes the first element of the new range and *new\_first* - 1 becomes the last element.

The assignments in the parallel *rotate\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last* - *first* assignments.

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **OutIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an output iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_first** – Refers to the begin of the destination range.

### Returns

The *rotate\_copy* algorithm returns a output iterator, The *rotate\_copy* algorithm returns the output iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> rotate_copy(ExPolicy &&policy,  
                                                                    FwdIter1 first, FwdIter1  
                                                                    new_first, FwdIter1 last,  
                                                                    FwdIter2 dest_first)
```

Copies the elements from the range [first, last), to another range beginning at *dest\_first* in such a way, that the element *new\_first* becomes the first element of the new range and *new\_first* - 1 becomes the last element. Executed according to the policy.

The assignments in the parallel *rotate\_copy* algorithm execute in sequential order in the calling thread.

The assignments in the parallel *rotate\_copy* algorithm execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last* - *first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new\_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_first** – Refers to the begin of the destination range.

### Returns

The *rotate\_copy* algorithm returns a *hpx::future*<*FwdIter2*> if the execution policy is of type

*parallel\_task\_policy* and returns `FwdIter2` otherwise. The *rotate\_copy* algorithm returns the output iterator to the element past the last element copied.

## hpx::includes

Defined in header `hpx/algorithm.hpp`<sup>664</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred =
    hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool>::type includes(ExPolicy &&policy, FwdIter1
    first1, FwdIter1 last1,
    FwdIter2 first2, FwdIter2
    last2, Pred &&op = Pred())
```

Returns true if every element from the sorted range  $[first2, last2)$  is found within the sorted range  $[first1, last1)$ . Also returns true if  $[first2, last2)$  is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*. Executed according to the policy.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where  $N1 = \text{std::distance}(first1, last1)$  and  $N2 = \text{std::distance}(first2, last2)$ .

---

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::less<>`

## Parameters

---

<sup>664</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

#### Returns

The *includes* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *includes* algorithm returns true every element from the sorted range  $[first2, last2)$  is found within the sorted range  $[first1, last1)$ . Also returns true if  $[first2, last2)$  is empty.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = hpx::parallel::detail::less>  
bool includes(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if every element from the sorted range  $[first2, last2)$  is found within the sorted range  $[first1, last1)$ . Also returns true if  $[first2, last2)$  is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*.

---

**Note:** At most  $2*(N1+N2-1)$  comparisons, where  $N1 = \text{std::distance}(first1, last1)$  and  $N2 = \text{std::distance}(first2, last2)$ .

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

#### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *includes* algorithm returns a *bool*. The *includes* algorithm returns true every element from the sorted range *[first2, last2)* is found within the sorted range *[first1, last1)*. Also returns true if *[first2, last2)* is empty.

## hpx::experimental::sort\_by\_key

Defined in header `hpx/algorithm.hpp`<sup>665</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

### Functions

```
template<typename ExPolicy, typename KeyIter, typename ValueIter, typename Compare =
detail::less>
util::detail::algorithm_result_t<ExPolicy, sort_by_key_result<KeyIter, ValueIter>> sort_by_key(ExPolicy
&&pol-
icy,
KeyIter
key_first,
KeyIter
key_last,
Val-
ueIter
value_first,
Com-
pare
&&comp
=
Com-
pare())
```

<sup>665</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

Sorts one range of data using keys supplied in another range. The key elements in the range [key\_first, key\_last) are sorted in ascending order with the corresponding elements in the value range moved to follow the sorted order. The algorithm is not stable, the order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i* + *n* is a valid iterator pointing to an element of the sequence, and INVOKE(comp, \*(i + n), \*i) == false.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std::distance}(\text{first}, \text{last})$  comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **KeyIter** – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **ValueIter** – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Compare** – The type of the function/function object to use (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **key\_first** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key\_last** – Refers to the end of the sequence of key elements the algorithm will be applied to.
- **value\_first** – Refers to the beginning of the sequence of value elements the algorithm will be applied to, the range of elements must match [key\_first, key\_last)
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

#### Returns

The *sort\_by\_key* algorithm returns a `hpx::future<sort_by_key_result<KeyIter, ValueIter>>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *otherwise*. The algorithm returns a pair holding an iterator pointing to the first element after the last element in the input key sequence and an iterator pointing to the first element after the last element in the input value sequence.

## hpx::adjacent\_difference

Defined in header `hpx/algorithm.hpp`<sup>666</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter1, typename FwdIter2>
FwdIter2 adjacent_difference(FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except \*result, which is assigned \*first.

---

**Note:** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.

#### Returns

The *adjacent\_difference* algorithm returns a *FwdIter2*. The *adjacent\_difference* algorithm returns an iterator to the element past the last element written.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy
                                                                                          &&policy,
                                                                                          FwdIter1 first,
                                                                                          FwdIter1 last,
                                                                                          FwdIter2 dest)
```

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except \*result, which is assigned \*first. Executed according to the policy.

The difference operations in the parallel *adjacent\_difference* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

<sup>666</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

The difference operations in the parallel *adjacent\_difference* invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.

#### Returns

The *adjacent\_difference* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *adjacent\_difference* algorithm returns an iterator to the element past the last element written.

```
template<typename FwdIter1, typename FwdIter2, typename Op>  
FwdIter2 adjacent_difference(FwdIter1 first, FwdIter1 last, FwdIter2 dest, Op &&op)
```

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except \*result, which is assigned \*first

---

**Note:** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent\_difference* requires *Op* to meet the requirements of *Copy-Constructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **op** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter1* can be dereferenced and then implicitly converted to the dereferenced type of *dest*.

### Returns

The *adjacent\_difference* algorithm returns *FwdIter2*. The *adjacent\_difference* algorithm returns an iterator to the element past the last element written.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy
                                                                                      &&policy,
                                                                                      FwdIter1 first,
                                                                                      FwdIter1 last,
                                                                                      FwdIter2 dest,
                                                                                      Op &&op)
```

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except \*result, which is assigned \*first

The difference operations in the parallel *adjacent\_difference* invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The difference operations in the parallel *adjacent\_difference* invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent\_difference* requires *Op* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **op** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter1* can be dereferenced and then implicitly converted to the dereferenced type of *dest*.

#### Returns

The *adjacent\_difference* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *adjacent\_difference* algorithm returns an iterator to the element past the last element written.

## hpx::stable\_sort

Defined in header `hpx/algorithm.hpp`<sup>667</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename RandomIt, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>  
void stable_sort(RandomIt first, RandomIt last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Sorts the elements in the range `[first, last)` in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object `comp` (defaults to using operator`<`()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i + n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel *stable\_sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std::distance}(\text{first}, \text{last})$  comparisons.

---

#### Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

---

<sup>667</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to `bool`, yields `true` if the first argument of the call is less than the second, and `false` otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

#### Returns

The `stable_sort` algorithm returns `void`.

```
template<typename ExPolicy, typename RandomIt, typename Comp = hpx::parallel::detail::less, typename
Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> stable_sort(ExPolicy &&policy, RandomIt first,
                                                                    RandomIt last, Comp &&comp =
                                                                    Comp(), Proj &&proj = Proj())
```

Sorts the elements in the range `[first, last)` in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object `comp` (defaults to using `operator<()`). Executed according to the policy.

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

`comp` has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std::distance}(\text{first}, \text{last})$  comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to `bool`, yields `true` if the first argument of the call is less than the second, and `false` otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

### Returns

The `stable_sort` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

## hpx::partial\_sort\_copy

Defined in header [hpx/algorithm.hpp](#)<sup>668</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename RandIter, typename Comp = hpx::parallel::detail::less>
RandIter partial_sort_copy(InIter first, InIter last, RandIter d_first, RandIter d_last, Comp &&comp =
    Comp())
```

Sorts some of the elements in the range `[first, last)` in ascending order, storing the result in the range `[d_first, d_last)`. At most `d_last - d_first` of the elements are placed sorted to the range `[d_first, d_first + n)` where `n` is the number of elements to sort (`n = min(last - first, d_last - d_first)`).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(\min(D, N)))$ , where  $N = \text{std::distance}(\text{first}, \text{last})$  and  $D = \text{std::distance}(\text{d\_first}, \text{d\_last})$  comparisons.

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

---

<sup>668</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **RandIter** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **d\_first** – Refers to the beginning of the destination range.
- **d\_last** – Refers to the end of the destination range.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to `detail::less`.

#### Returns

The *partial\_sort\_copy* algorithm returns a *RandomIt*. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. `d_first + min(last - first, d_last - d_first)`

```
template<typename ExPolicy, typename FwdIter, typename RandIter, typename Comp =
    hpx::parallel::detail::less>
parallel::util::detail::algorithm_result_t<ExPolicy, RandIter> partial_sort_copy(ExPolicy &&policy,
    FwdIter first, FwdIter
    last, RandIter d_first,
    RandIter d_last, Comp
    &&comp = Comp())
```

Sorts some of the elements in the range `[first, last)` in ascending order, storing the result in the range `[d_first, d_last)`. At most `d_last - d_first` of the elements are placed sorted to the range `[d_first, d_first + n)` where `n` is the number of elements to sort (`n = min(last - first, d_last - d_first)`). Executed according to the policy.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(\min(D, N)))$ , where  $N = \text{std::distance}(\text{first}, \text{last})$  and  $D = \text{std::distance}(\text{d\_first}, \text{d\_last})$  comparisons.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **RandIter** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **d\_first** – Refers to the beginning of the destination range.
- **d\_last** – Refers to the end of the destination range.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to `bool`, yields `true` if the first argument of the call is less than the second, and `false` otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator. This defaults to `detail::less`.

#### Returns

The *partial\_sort\_copy* algorithm returns a `hpx::future<RandomIt>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandomIt* otherwise. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. `d_first + min(last - first, d_last - d_first)`

## hpx::uninitialized\_copy, hpx::uninitialized\_copy\_n

Defined in header `hpx/algorithm.hpp`<sup>669</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename FwdIter>
FwdIter uninitialized_copy(InIter first, InIter last, FwdIter dest)
```

Copies the elements in the range, defined by `[first, last)`, to an uninitialized memory area beginning at `dest`. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

---

<sup>669</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

#### Returns

The *uninitialized\_copy* algorithm returns *FwdIter*. The *uninitialized\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> uninitialized_copy(ExPolicy
&&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2 dest)
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

**Returns**

The *uninitialized\_copy* algorithm returns a *hpx::future<FwdIter2>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename Size, typename FwdIter>  
FwdIter uninitialized_copy_n(InIter first, Size count, FwdIter dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy\_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

---

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns**

The *uninitialized\_copy\_n* algorithm returns a returns *FwdIter*. The *uninitialized\_copy\_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> uninitialized_copy_n(ExPolicy  
                                                                                          &&policy,  
                                                                                          FwdIter1 first,  
                                                                                          Size count,  
                                                                                          FwdIter2 dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized\_copy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_copy\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

### Returns

The *uninitialized\_copy\_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *uninitialized\_copy\_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx::reduce\_deterministic

Defined in header [hpx/algorithm.hpp](#)<sup>670</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

---

<sup>670</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename ExPolicy, typename FwdIter, typename F, typename T = typename
std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> reduce_deterministic(ExPolicy &&policy,
                                          FwdIter first, FwdIter
                                          last, T init, F &&f)
```

Returns GENERALIZED\_SUM(f, init, \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate  $f$ .

---

---

**Note:** GENERALIZED\_SUM(op, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(op, b1, ..., bK), GENERALIZED\_SUM(op, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires  $F$  to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

## Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **init** – The initial value for the generalized sum.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types *Type1* *Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

### Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter, typename T = typename
std::iterator_traits<FwdIter>::value_type>
util::detail::algorithm_result_t<ExPolicy, T> reduce_deterministic(ExPolicy &&policy, FwdIter first,
                                                                    FwdIter last, T init)
```

Returns GENERALIZED\_SUM(+, init, \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the operator+().

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

#### Returns

The *reduce* algorithm returns a `hpx::future<T>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum (applying `operator+()`) over the elements given by the input range `[first, last)`.

```
template<typename ExPolicy, typename FwdIter>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce_deter
```

Returns `GENERALIZED_SUM(+, T(), *first, ..., *(first + (last - first) - 1))`. Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the `operator+()`.

---

---

**Note:** The type of the initial value (and the result type) *T* is determined from the `value_type` of the used *FwdIter*.

---

---

**Note:** `GENERALIZED_SUM(+, a1, ..., aN)` is defined as follows:

- `a1` when *N* is 1
- `op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN))`, where:

- $b_1, \dots, b_N$  may be any permutation of  $a_1, \dots, a_N$  and
- $1 < K+1 = M \leq N$ .

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

### Returns

The *reduce* algorithm returns a `hpx::future<T>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns `T` otherwise (where `T` is the `value_type` of `FwdIter`). The *reduce* algorithm returns the result of the generalized sum (applying `operator+()`) over the elements given by the input range `[first, last)`.

```
template<typename FwdIter, typename F, typename T = typename std::iterator_traits<FwdIter>::value_type>
T reduce_deterministic(FwdIter first, FwdIter last, T init, F &&f)
```

Returns `GENERALIZED_SUM(f, init, *first, ..., *(first + (last - first) - 1))`. Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *f*.

**Note:** `GENERALIZED_SUM(op, a1, ..., aN)` is defined as follows:

- $a_1$  when  $N$  is 1
- `op(GENERALIZED_SUM(op, b1, ..., bK), GENERALIZED_SUM(op, bM, ..., bN))`, where:
  - $b_1, \dots, b_N$  may be any permutation of  $a_1, \dots, a_N$  and
  - $1 < K+1 = M \leq N$ .

### Template Parameters

- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.

- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types *Type1* *Ret* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to any of those types.

#### Returns

The *reduce* algorithm returns *T*. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

```
template<typename FwdIter, typename T = typename std::iterator_traits<FwdIter>::value_type>
T reduce_deterministic(FwdIter first, FwdIter last, T init)
```

Returns GENERALIZED\_SUM(+, init, \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the operator+().

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

**Returns**

The *reduce* algorithm returns a *T*. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

```
template<typename FwdIter>
```

```
std::iterator_traits<FwdIter>::value_type reduce_deterministic(FwdIter first, FwdIter last)
```

Returns GENERALIZED\_SUM(+, T(), \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the operator+().

---

---

**Note:** The type of the initial value (and the result type) *T* is determined from the value\_type of the used *FwdIter*.

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

**Template Parameters**

**FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The *reduce* algorithm returns *T* (where T is the value\_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

## hpx::ends\_with

Defined in header [hpx/algorithm.hpp](#)<sup>671</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter1, typename InIter2, typename Pred = hpx::parallel::detail::equal_to>  
bool ends_with(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred = Pred())
```

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2)

The assignments in the parallel *ends\_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate.

---

### Template Parameters

- **InIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a input iterator.
- **Pred** – The binary predicate that compares the elements. This defaults to *hpx::parallel::detail::equal\_to*.

### Parameters

- **first1** – Refers to the beginning of the source range.
- **last1** – Refers to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

### Returns

The *ends\_with* algorithm returns *bool*. The *ends\_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred =  
ranges::equal_to>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type ends_with(ExPolicy &&policy, FwdIter1  
first1, FwdIter1 last1, FwdIter2  
first2, FwdIter2 last2, Pred  
&&pred = Pred())
```

---

<sup>671</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2). Executed according to the policy.

The assignments in the parallel *ends\_with* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *ends\_with* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The binary predicate that compares the elements. This defaults to *ranges::equal\_to*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Refers to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Refers to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

### Returns

The *ends\_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *ends\_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

## hpx::fill, hpx::fill\_n

Defined in header [hpx/algorithm.hpp](#)<sup>672</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename T>  
util::detail::algorithm_result_t<ExPolicy> fill(ExPolicy &&policy, FwdIter first, FwdIter last, T value)
```

Assigns the given value to the elements in the range [first, last). Executed according to the policy.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

### Returns

The *fill* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *void*).

```
template<typename FwdIter, typename T>
```

---

<sup>672</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

void **fill**(*FwdIter* first, *FwdIter* last, *T* value)

Assigns the given value to the elements in the range [first, last).

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

#### Returns

The *fill* algorithm returns a *void*.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter> fill_n(ExPolicy &&policy, FwdIter first, Size count, T
                                                    value)
```

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise. Executed according to the policy.

The comparisons in the parallel *fill\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, for count > 0.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns**

The *fill\_n* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *void*).

```
template<typename FwdIter, typename Size, typename T>  
FwdIter fill_n(FwdIter first, Size count, T value)
```

Assigns the given value *value* to the first *count* elements in the range beginning at *first* if *count* > 0. Does nothing otherwise.

---

**Note:** Complexity: Performs exactly *count* assignments, for *count* > 0.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns**

The *fill\_n* algorithm returns a *FwdIter*.

**hpx::uninitialized\_fill, hpx::uninitialized\_fill\_n**

Defined in header [hpx/algorithm.hpp](#)<sup>673</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

<sup>673</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename FwdIter, typename T>
void uninitialized_fill(FwdIter first, FwdIter last, T const &value)
```

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

---

**Note:** Complexity: Linear in the distance between *first* and *last*

---

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

### Returns

The *uninitialized\_fill* algorithm returns nothing

```
template<typename ExPolicy, typename FwdIter, typename T>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> uninitialized_fill(ExPolicy &&policy, FwdIter
first, FwdIter last, T const
&value)
```

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel *uninitialized\_fill* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The initializations in the parallel *uninitialized\_fill* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns**

The *uninitialized\_fill* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

```
template<typename FwdIter, typename Size, typename T>  
FwdIter uninitialized_fill_n(FwdIter first, Size count, T const &value)
```

Copies the given *value* value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects.

---

**Note:** Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns**

The *uninitialized\_fill\_n* algorithm returns a *returns FwdIter*. The *uninitialized\_fill\_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename T>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> uninitialized_fill_n(ExPolicy  
                                                                                      &&policy,  
                                                                                      FwdIter first,  
                                                                                      Size count, T  
                                                                                      const &value)
```

Copies the given *value* value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel *uninitialized\_fill\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The initializations in the parallel *uninitialized\_fill\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **T** – The type of the value to be assigned (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **value** – The value to be assigned.

### Returns

The *uninitialized\_fill\_n* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_fill\_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

## hpx::set\_union

Defined in header [hpx/algorithm.hpp](http://github.com/HPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp)<sup>674</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename
Pred = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter3> set_union(ExPolicy &&policy, FwdIter1
first1, FwdIter1 last1,
FwdIter2 first2, FwdIter2
last2, FwdIter3 dest, Pred
&&op = Pred())
```

---

<sup>674</sup> <http://github.com/HPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

Constructs a sorted range beginning at *dest* consisting of all elements present in one or both sorted ranges *[first1, last1)* and *[first2, last2)*. This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in *[first1, last1)* and *n* times in *[first2, last2)*, then all *m* elements will be copied from *[first1, last1)* to *dest*, preserving order, and then exactly `std::max(n-m, 0)` elements will be copied from *[first2, last2)* to *dest*, also preserving order.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

### Returns

The `set_union` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter3* otherwise. The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred =
hpx::parallel::detail::less>
FwdIter3 set_union(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred
&&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in one or both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in `[first1, last1)` and *n* times in `[first2, last2)`, then all *m* elements will be copied from `[first1, last1)` to `dest`, preserving order, and then exactly `std::max(n-m, 0)` elements will be copied from `[first2, last2)` to `dest`, also preserving order.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

#### Returns

The *set\_union* algorithm returns a *FwdIter3*. The *set\_union* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx::lexicographical\_compare

Defined in header `hpx/algorithm.hpp`<sup>675</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter1, typename InIter2, typename Pred = hpx::parallel::detail::less>  
bool lexicographical_compare(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred)
```

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 = \text{std::distance}(\text{first1}, \text{last})$  and  $N2 = \text{std::distance}(\text{first2}, \text{last2})$ .

---

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically *less* or *greater* than the other
- If one range is a prefix of another, the shorter range is lexicographically *less* than the other

---

<sup>675</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
- An empty range is lexicographically *less* than any non-empty range
- Two empty ranges are lexicographically *equal*

### Template Parameters

- **InIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to

### Returns

The *lexicographically\_compare* algorithm returns a *bool* if the execution policy object is not passed in. The *lexicographical\_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred =
    hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> lexicographical_compare(ExPolicy
    &&policy,
    FwdIter1 first1,
    FwdIter1 last1,
    FwdIter2 first2,
    FwdIter2 last2,
    Pred &&pred)
```

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *lexicographical\_compare* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 * \min(N1, N2)$  applications of the comparison operation, where  $N1 = \text{std::distance}(\text{first1}, \text{last})$  and  $N2 = \text{std::distance}(\text{first2}, \text{last2})$ .

---

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
  - The first mismatching element defines which range is lexicographically *less* or *greater* than the other
  - If one range is a prefix of another, the shorter range is lexicographically *less* than the other
  - If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
  - An empty range is lexicographically *less* than any non-empty range
  - Two empty ranges are lexicographically *equal*
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical\_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to

#### Returns

The *lexicographically\_compare* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The

*lexicographically\_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. *range* [first2, last2), it returns false.

## hpx::experimental::reduction\_multiplies

Defined in header `hpx/algorithm.hpp`<sup>676</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

### Functions

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::multiplies<T>> reduction_multiplies(T
                                                                    &var)
```

The function template *reduction\_multiplies* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses `std::multiplies{ }` as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction\_multiplies* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the `std::multiplies{ }` operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

---

#### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

#### Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.

---

<sup>676</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

**Returns**

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::multiplies<T>> reduction_multiplies(T
                                                                    &var,
                                                                    T
                                                                    const
                                                                    &iden-
                                                                    tity)
```

**hpx::sort**

Defined in header `hpx/algorithm.hpp`<sup>677</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

```
template<typename RandomIt, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
void sort(RandomIt first, RandomIt last, Comp &&comp, Proj &&proj = Proj())
```

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object *comp* (defaults to using `operator<()`).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i* + *n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

*comp* has to induce a strict weak ordering on the values.

The assignments in the parallel *sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std::distance}(\text{first}, \text{last})$  comparisons.

---

**Template Parameters**

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

---

<sup>677</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to `bool`, yields `true` if the first argument of the call is less than the second, and `false` otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

### Returns

The *sort* algorithm returns *void*.

```
template<typename ExPolicy, typename RandomIt, typename Comp = hpx::parallel::detail::less, typename
Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> sort(ExPolicy &&policy, RandomIt first, RandomIt
last, Comp &&comp, Proj &&proj)
```

Sorts the elements in the range `[first, last)` in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object `comp` (defaults to using `operator<()`). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator *i* pointing to the sequence and every non-negative integer *n* such that *i* + *n* is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(N \log(N))$ , where  $N = \text{std::distance}(\text{first}, \text{last})$  comparisons.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to `bool`, yields `true` if the first argument of the call is less than the second, and `false` otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

#### Returns

The *sort* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

### `hpx::merge`, `hpx::inplace_merge`

Defined in header `hpx/algorithm.hpp`<sup>678</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

#### Functions

```
template<typename ExPolicy, typename RandIter1, typename RandIter2, typename RandIter3,
        typename Comp = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, RandIter3> merge(ExPolicy &&policy, RandIter1
                                                                    first1, RandIter1 last1, RandIter2
                                                                    first2, RandIter2 last2, RandIter3
                                                                    dest, Comp &&comp = Comp())
```

Merges two sorted ranges `[first1, last1)` and `[first2, last2)` into one sorted range beginning at *dest*. The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges. Executed according to the policy.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs  $O(\text{std::distance}(\text{first1}, \text{last1}) + \text{std::distance}(\text{first2}, \text{last2}))$  applications of the comparison *comp* and each projection.

---

#### Template Parameters

---

<sup>678</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter1* and *RandIter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

#### Returns

The *merge* algorithm returns a `hpx::future<RandIter3>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandIter3* otherwise. The *merge* algorithm returns the destination iterator to the end of the *dest* range.

```
template<typename RandIter1, typename RandIter2, typename RandIter3, typename Comp =
hpx::parallel::detail::less>
RandIter3 merge(RandIter1 first1, RandIter1 last1, RandIter2 first2, RandIter2 last2, RandIter3 dest, Comp
&&comp = Comp())
```

Merges two sorted ranges `[first1, last1)` and `[first2, last2)` into one sorted range beginning at *dest*. The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

---

**Note:** Complexity: Performs  $O(\text{std::distance}(\text{first1}, \text{last1}) + \text{std::distance}(\text{first2}, \text{last2}))$  applications of the comparison *comp* and each projection.

---

### Template Parameters

- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter1* and *RandIter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

### Returns

The *merge* algorithm returns a *RandIter3*. The *merge* algorithm returns the destination iterator to the end of the *dest* range.

```
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> inplace_merge(ExPolicy &&policy, RandIter first,
                                                                    RandIter middle, RandIter last,
                                                                    Comp &&comp = Comp())
```

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. Executed according to the policy.

The assignments in the parallel *inplace\_merge* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *inplace\_merge* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs  $O(\text{std::distance}(\text{first}, \text{last}))$  applications of the comparison *comp* and each projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace\_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

### Returns

The *inplace\_merge* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns void otherwise. The *inplace\_merge* algorithm returns the source iterator *last*.

```
template<typename RandIter, typename Comp = hpx::parallel::detail::less>
void inplace_merge(RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

---

**Note:** Complexity: Performs  $O(\text{std::distance}(\text{first}, \text{last}))$  applications of the comparison *comp* and each projection.

---

### Template Parameters

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace\_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

#### Parameters

- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

#### Returns

The *inplace\_merge* algorithm returns a *void*. The *inplace\_merge* algorithm returns the source iterator *last*.

## hpx::generate, hpx::generate\_n

Defined in header `hpx/algorithm.hpp`<sup>679</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename F>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> generate(ExPolicy &&policy, FwdIter  
first, FwdIter last, F &&f)
```

Assign each element in range  $[first, last)$  a value generated by the given function object *f*. Executed according to the policy.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

---

#### Template Parameters

---

<sup>679</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

#### Returns

The *generate* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise.

```
template<typename FwdIter, typename F>
void generate(FwdIter first, FwdIter last, F &&f)
```

Assign each element in range [*first*, *last*) a value generated by the given function object *f*.

---

**Note:** Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```
Ret fun();
```

The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

### Returns

The *generate* algorithm returns void.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> generate_n(ExPolicy &&policy, FwdIter
                                                                    first, Size count, F &&f)
```

Assigns each element in range [*first*, *first*+) a value generated by the given function object *f*. Executed according to the policy.

The assignments in the parallel *generate\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Exactly *count* invocations of *f* and assignments, for count > 0.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

```
Ret fun();
```

The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

### Returns

The *generate\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. *generate\_n* algorithm returns iterator one past the last element assigned if count>0, first otherwise.

```
template<typename FwdIter, typename Size, typename F>
```

*FwdIter* **generate\_n**(*FwdIter* first, *Size* count, *F* &&*f*)

Assigns each element in range  $[first, first+)$  a value generated by the given function object *f*.

---

**Note:** Complexity: Exactly *count* invocations of *f* and assignments, for *count* > 0.

---

#### Template Parameters

- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

|                    |
|--------------------|
| Ret <i>fun</i> (); |
|--------------------|

The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

#### Returns

The *generate\_n* algorithm returns a *FwdIter*. *generate\_n* algorithm returns iterator one past the last element assigned if *count*>0, first otherwise.

## hpx::uninitialized\_value\_construct, hpx::uninitialized\_value\_construct\_n

Defined in header [hpx/algorithm.hpp](#)<sup>680</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter>
void uninitialized_value_construct(FwdIter first, FwdIter last)
```

Constructs objects of type `typename iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

<sup>680</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

**Template Parameters**

**FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The *uninitialized\_value\_construct* algorithm returns nothing

```
template<typename ExPolicy, typename FwdIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> uninitialized_value_construct(ExPolicy
                                                                                          &&policy,
                                                                                          FwdIter first,
                                                                                          FwdIter last)
```

Constructs objects of type `typename iterator_traits<ForwardIt> ::value_type` in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_value\_construct* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The *uninitialized\_value\_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns nothing otherwise.

```
template<typename FwdIter, typename Size>
```

*FwdIter* **uninitialized\_value\_construct\_n**(*FwdIter* first, *Size* count)

Constructs objects of type `typename iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range `[first, first + count)` by value-initialization. If an exception is thrown during the initialization, the function has no effects.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

#### Returns

The *uninitialized\_value\_construct\_n* algorithm returns a *FwdIter*. The *uninitialized\_value\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Size>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> uninitialized_value_construct_n(ExPolicy
&&pol-
icy,
FwdIter
first,
Size
count)
```

Constructs objects of type `typename iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range `[first, first + count)` by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_value\_construct\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* assignments, if *count* > 0, no assignments otherwise.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

#### Returns

The *uninitialized\_value\_construct\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_value\_construct\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

### hpx::is\_heap, hpx::is\_heap\_until

Defined in header [hpx/algorithm.hpp](#)<sup>681</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

#### Functions

```
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_heap(ExPolicy &&policy, RandIter first,
                                                                    RandIter last, Comp &&comp =
                                                                    Comp())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator<()). Executed according to the policy.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

---

<sup>681</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

#### Returns

The *is\_heap* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *is\_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename RandIter, typename Comp = hpx::parallel::detail::less>
bool is_heap(RandIter first, RandIter last, Comp &&comp = Comp())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

#### Template Parameters

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

#### Returns

The *is\_heap* a *bool*. The *is\_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>
```

```
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, RandIter> is_heap_until(ExPolicy &&policy,
                                                                                   RandIter first, RandIter
                                                                                   last, Comp &&comp =
                                                                                   Comp())
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()). Executed according to the policy.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

### Returns

The *is\_heap\_until* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *RandIter* otherwise. The *is\_heap\_until* algorithm returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

```
template<typename RandIter, typename Comp = hpx::parallel::detail::less>
RandIter is_heap_until(RandIter first, RandIter last, Comp &&comp = Comp())
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

### Template Parameters

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

### Returns

The *is\_heap\_until* algorithm returns a *RandIter*. The *is\_heap\_until* algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

## hpx::destroy, hpx::destroy\_n

Defined in header [hpx/algorithm.hpp](#)<sup>682</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result_t<ExPolicy> destroy(ExPolicy &&policy, FwdIter first, FwdIter last)
```

Destroys objects of type `typename iterator_traits<ForwardIt>::value_type` in the range [first, last). Executed according to the policy.

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* operations.

---

<sup>682</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The *destroy* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename FwdIter>
void destroy(FwdIter first, FwdIter last)
```

Destroys objects of type *typename iterator\_traits<ForwardIt>::value\_type* in the range [first, last).

---

**Note:** Complexity: Performs exactly *last - first* operations.

---

**Template Parameters**

**FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The *destroy* algorithm returns a *void*

```
template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result_t<ExPolicy, FwdIter> destroy_n(ExPolicy &&policy, FwdIter first, Size count)
```

Destroys objects of type *typename iterator\_traits<ForwardIt>::value\_type* in the range [first, first + count). Executed according to the policy.

The operations in the parallel *destroy\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *count* operations, if count > 0, no assignments otherwise.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns**

The *destroy\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *destroy\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename FwdIter, typename Size>
FwdIter destroy_n(FwdIter first, Size count)
```

Destroys objects of type *typename iterator\_traits<ForwardIt>::value\_type* in the range *[first, first + count)*.

---

**Note:** Complexity: Performs exactly *count* operations, if *count* > 0, no assignments otherwise.

---

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

**Returns**

The *destroy\_n* algorithm returns a *FwdIter* . The *destroy\_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

## hpx::count, hpx::count\_if

Defined in header [hpx/algorithm.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp)<sup>683</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::difference_type>::type count(ExPolicy
                                                                                                     &&pol-
                                                                                                     icy,
                                                                                                     FwdIter
                                                                                                     first,
                                                                                                     FwdIter
                                                                                                     last,
                                                                                                     T
                                                                                                     const
                                                                                                     &value)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*. Executed according to the policy.

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* comparisons.

---

---

**Note:** The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to search for (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

---

<sup>683</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

**Returns**

The *count* algorithm returns a *hpx::future<difference\_type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *std::iterator\_traits<FwdIterB>::difference\_type*). The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename InIter, typename T>
std::iterator_traits<InIter>::difference_type count(InIter first, InIter last, T const &value)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*.

---

**Note:** Complexity: Performs exactly *last - first* comparisons.

---

**Template Parameters**

- **InIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

**Returns**

The *count* algorithm returns a *difference\_type* (where *difference\_type* is defined by *std::iterator\_traits<InIter>::difference\_type*). The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::difference_type>::type count_if(ExPolicy
&&pol-
icy,
FwdIter
first,
FwdIter
last,
F
&&f)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true. Executed according to the policy.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

---

---

**Note:** The assignments in the parallel *count\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count\_if* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *count\_if* algorithm returns *hpx::future<difference\_type>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *difference\_type* otherwise (where *difference\_type* is defined by *std::iterator\_traits<FwdIter>::difference\_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

```
template<typename InIter, typename F>  
std::iterator_traits<InIter>::difference_type count_if(InIter first, InIter last, F &&f)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

### Template Parameters

- **InIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count\_if* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *count\_if* algorithm returns *difference\_type* (where a *difference\_type* is defined by *std::iterator\_traits<InIter>::difference\_type*). The *count* algorithm returns the number of elements satisfying the given criteria.

## hpx::partition, hpx::stable\_partition, hpx::partition\_copy

Defined in header `hpx/algorithm.hpp`<sup>684</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename FwdIter, typename Pred, typename Proj = hpx::identity>
FwdIter partition(FwdIter first, FwdIter last, Pred &&pred, Proj &&proj = Proj())
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: At most  $2 * (last - first)$  swaps. Exactly *last - first* applications of the predicate and projection.

#### Template Parameters

<sup>684</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *Copy-Constructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *partition* algorithm returns *FwdIter*. The *partition* algorithm returns the iterator to the first element of the second group.

```
template<typename ExPolicy, typename FwdIter, typename Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> partition(ExPolicy &&policy, FwdIter first,
                                                                    FwdIter last, Pred &&pred, Proj
                                                                    &&proj = Proj())
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 * (\text{last} - \text{first})$  swaps. Exactly *last - first* applications of the predicate and projection.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *partition* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *parallel\_task\_policy* and returns *FwdIter* otherwise. The *partition* algorithm returns the iterator to the first element of the second group.

```
template<typename BidirIter, typename F, typename Proj = hpx::identity>
BidirIter stable_partition(BidirIter first, BidirIter last, F &&f, Proj &&proj = Proj())
```

Permutes the elements in the range [first, last) such that there exists an iterator *i* such that for every iterator *j* in the range [first, *i*) INVOKE(*f*, INVOKE(*proj*, \**j*)) != false, and for every iterator *k* in the range [*i*, last), INVOKE(*f*, INVOKE(*proj*, \**k*)) == false

The invocations of *f* in the parallel *stable\_partition* algorithm invoked without an execution policy object executes in sequential order in the calling thread.

---

**Note:** Complexity: At most (last - first) \* log(last - first) swaps, but only linear number of swaps if there is enough extra memory. Exactly *last - first* applications of the predicate and projection.

---

#### Template Parameters

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

### Returns

The *stable\_partition* algorithm returns an iterator *i* such that for every iterator *j* in the range [first, *i*),  $f(*j) \neq \text{false}$  INVOKE(*f*, INVOKE(*proj*, *\*j*))  $\neq \text{false}$ , and for every iterator *k* in the range [*i*, last),  $f(*k) == \text{false}$  INVOKE(*f*, INVOKE(*proj*, *\*k*))  $== \text{false}$ . The relative order of the elements in both groups is preserved.

```
template<typename ExPolicy, typename BidirIter, typename F, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result_t<ExPolicy, BidirIter> stable_partition(ExPolicy &&policy,
                                         BidirIter first, BidirIter
                                         last, F &&f, Proj &&proj
                                         = Proj())
```

Permutes the elements in the range [first, last) such that there exists an iterator *i* such that for every iterator *j* in the range [first, *i*) INVOKE(*f*, INVOKE(*proj*, *\*j*))  $\neq \text{false}$ , and for every iterator *k* in the range [*i*, last), INVOKE(*f*, INVOKE(*proj*, *\*k*))  $== \text{false}$

The invocations of *f* in the parallel *stable\_partition* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The invocations of *f* in the parallel *stable\_partition* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $(\text{last} - \text{first}) * \log(\text{last} - \text{first})$  swaps, but only linear number of swaps if there is enough extra memory. Exactly *last - first* applications of the predicate and projection.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

#### Returns

The *stable\_partition* algorithm returns an iterator *i* such that for every iterator *j* in the range [first, *i*), *f*(\*j) != false INVOKE(*f*, INVOKE(*proj*, \*j)) != false, and for every iterator *k* in the range [*i*, last), *f*(\*k) == false INVOKE(*f*, INVOKE(*proj*, \*k)) == false. The relative order of the elements in both groups is preserved. If the execution policy is of type *parallel\_task\_policy* the algorithm returns a *future*<> referring to this iterator.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj =
hpx::identity>
std::pair<FwdIter2, FwdIter3> partition_copy(FwdIter1 first, FwdIter1 last, FwdIter2 dest_true, FwdIter3
dest_false, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred* are copied to the range beginning at *dest\_true*. The rest of the elements are copied to the range beginning at *dest\_false*. The order of the elements is preserved.

The assignments in the parallel *partition\_copy* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *partition\_copy* algorithm returns *std::pair<OutIter1, OutIter2>*. The *partition\_copy* algorithm returns the pair of the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename
Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter2, FwdIter3>> partition_copy(ExPolicy
&&policy,
FwdIter1
first,
FwdIter1
last,
FwdIter2
dest_true,
FwdIter3
dest_false,
Pred
&&pred,
Proj
&&proj
=
Proj())
```

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred*, are copied to the range beginning at *dest\_true*. The rest of the elements are copied to the range beginning at *dest\_false*. The order of the elements is preserved.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition\_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **dest\_false** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

#### Returns

The *partition\_copy* algorithm returns a `hpx::future<std::pair<OutIter1, OutIter2>>` if the execution policy is of type *parallel\_task\_policy* and returns `std::pair<OutIter1, OutIter2>` otherwise. The *partition\_copy* algorithm returns the pair of the destination iterator to the end of the *dest\_true* range, and the destination iterator to the end of the *dest\_false* range.

### hpx/parallel/algorithms/transform\_reduce\_binary.hpp

Defined in header `hpx/parallel/algorithms/transform_reduce_binary.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx::shift\_left

Defined in header `hpx/algorithm.hpp`<sup>685</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

#### Functions

```
template<typename FwdIter, typename Size>  
FwdIter shift_left(FwdIter first, FwdIter last, Size n)
```

Shifts the elements in the range `[first, last)` by `n` positions towards the beginning of the range. For every integer `i` in `[0, last - first)`

- `n`), moves the element originally at position `first + n + i` to position `first + i`.

The assignment operations in the parallel *shift\_left* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: At most `(last - first) - n` assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

#### Template Parameters

---

<sup>685</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

#### Returns

The *shift\_left* algorithm returns *FwdIter*. The *shift\_left* algorithm returns an iterator to the end of the resulting range. Specifically: If *n* is 0 or  $n \geq (\text{last} - \text{first})$ , does nothing and returns *last* and *first* respectively. Otherwise returns  $\text{first} + ((\text{last} - \text{first}) - n)$ .

```
template<typename ExPolicy, typename FwdIter, typename Size>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter> shift_left(ExPolicy &&policy, FwdIter
                                                                    first, FwdIter last, Size n)
```

Shifts the elements in the range  $[\text{first}, \text{last})$  by *n* positions towards the beginning of the range. For every integer *i* in  $[0, \text{last} - \text{first})$

- *n*), moves the element originally at position  $\text{first} + n + i$  to position  $\text{first} + i$ . Executed according to the policy.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift\_left* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $(\text{last} - \text{first}) - n$  assignments.

---

---

**Note:** The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

#### Returns

The *shift\_left* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *shift\_left* algorithm returns an iterator to the end of the resulting range. Specifically: If *n* is 0, does nothing and returns *last*. If *n*  $\geq$  (*last* - *first*), does nothing and returns *first*. Otherwise returns *first* + ((*last* - *first*) - *n*).

## hpx::set\_intersection

Defined in header `hpx/algorithm.hpp`<sup>686</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename  
Pred = hpx::parallel::detail::less>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter3> set_intersection(ExPolicy &&policy,  
                                             FwdIter1 first1,  
                                             FwdIter1 last1,  
                                             FwdIter2 first2,  
                                             FwdIter2 last2,  
                                             FwdIter3 dest, Pred  
                                             &&op = Pred())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in both sorted ranges [*first1*, *last1*) and [*first2*, *last2*). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in [*first1*, *last1*) and *n* times in [*first2*, *last2*), the first `std::min(m, n)` elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

<sup>686</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_intersection* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

### Returns

The *set\_intersection* algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter3* otherwise. The *set\_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred =
hpx::parallel::detail::less>
```

*FwdIter3* **set\_intersection**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at *dest* consisting of all elements present in both sorted ranges [*first1*, *last1*) and [*first2*, *last2*). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

If some element is found *m* times in [*first1*, *last1*) and *n* times in [*first2*, *last2*), the first `std::min(m, n)` elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_intersection* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::less<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

**Returns**

The *set\_intersection* algorithm returns a *FwdIter3*. The *set\_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**hpx::inclusive\_scan**

Defined in header `hpx/algorithm.hpp`<sup>687</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

```
template<typename InIter, typename OutIter>
OutIter inclusive_scan(InIter first, InIter last, OutIter dest)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, \*first, ..., \*(first + (i - result))).

The reduce operations in the parallel *inclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*, here `std::plus<>()`.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

---

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

---

<sup>687</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **dest** – Refers to the beginning of the destination range.

#### Returns

The *inclusive\_scan* algorithm returns *OutIter*. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> inclusive_scan(ExPolicy &&policy,
                                                                                      FwdIter1 first,
                                                                                      FwdIter1 last, FwdIter2
                                                                                      dest)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, \*first, ..., \*(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*, here `std::plus<>()`.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, *a*1, ..., *a*N) is defined as:

- *a*1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, *a*1, ..., *a*K)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, *a*M, ..., *a*N) where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

#### Returns

The *inclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename OutIter, typename Op>
OutIter inclusive_scan(InIter first, InIter last, OutIter dest, Op &&op)
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, ..., *(first + (i - result)))`.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN)` is defined as:

- `a1` when `N` is 1
  - `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK)`
    - `GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN)` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

#### Returns

The *inclusive\_scan* algorithm returns *OutIter*. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> inclusive_scan(ExPolicy &&policy,
                                          FwdIter1 first,
                                          FwdIter1 last, FwdIter2
                                          dest, Op &&op)
```

Assigns through each iterator *i* in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, ..., *(first + (i - result)))`. Executed according to the policy.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN)` is defined as:

- `a1` when *N* is 1
  - `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK)`
    - `GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN)` where  $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

### Returns

The *inclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename OutIter, typename Op, typename T>
```

```
OutIter inclusive_scan(InIter first, InIter last, OutIter dest, Op &&op, T init)
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, ..., *(first + (i - result)))`.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

---

- $a_1$  when *N* is 1
  - $op(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, a_1, \dots, a_K), \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, a_M, \dots, a_N))$  where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.

- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

#### Returns

The *inclusive\_scan* algorithm returns *OutIter*. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename T>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> inclusive_scan(ExPolicy &&policy,
                                          FwdIter1 first,
                                          FwdIter1 last, FwdIter2
                                          dest, Op &&op, T init)
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, ..., *(first + (i - result)))`. Executed according to the policy.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when *N* is 1
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

### Returns

The *inclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## `hpx::is_sorted`, `hpx::is_sorted_until`

Defined in header `hpx/algorithm.hpp`<sup>688</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

<sup>688</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename FwdIter, typename Pred = hpx::parallel::detail::less>  
bool is_sorted(FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel *is\_sorted* algorithm executes in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N$  = distance(first, last).  $S$  = number of partitions

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *is\_sorted* algorithm returns a *bool*. The *is\_sorted* algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::less>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_sorted(ExPolicy &&policy, FwdIter first,  
                                                                    FwdIter last, Pred &&pred =  
                                                                    Pred())
```

Determines if the range [first, last) is sorted. Uses pred to compare elements. Executed according to the policy.

The comparison operations in the parallel *is\_sorted* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_sorted* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N$  = distance(first, last).  $S$  = number of partitions

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is\_sorted* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *is\_sorted* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task\_execution\_policy* and returns *bool* otherwise. The *is\_sorted* algorithm returns a *bool* if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```
template<typename FwdIter, typename Pred = hpx::parallel::detail::less>
FwdIter is_sorted_until(FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel *is\_sorted\_until* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: at most  $(N+S-1)$  comparisons where  $N$  = distance(first, last).  $S$  = number of partitions

---

### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *is\_sorted\_until* algorithm returns a *FwdIter*. The *is\_sorted\_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type is_sorted_until(ExPolicy &&policy,
                                                                                      FwdIter first,
                                                                                      FwdIter last, Pred
                                                                                      &&pred = Pred())
```

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator. Executed according to the policy.

The comparison operations in the parallel *is\_sorted\_until* algorithm invoked with an execution policy object of type *sequenced\_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is\_sorted\_until* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: at most (N+S-1) comparisons where *N* = distance(first, last). *S* = number of partitions

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is\_sorted\_until* requires *Pred* to meet the requirements of *Copy-Constructible*. This defaults to `std::less<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *is\_sorted\_until* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task\_execution\_policy* and returns *FwdIter* otherwise. The *is\_sorted\_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

## hpx::experimental::reduction\_bit\_xor

Defined in header `hpx/algorithm.hpp`<sup>689</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

#### Functions

template<typename **T**>

constexpr *hpx::parallel::detail::reduction\_helper<T, std::bit\_xor<T>>* **reduction\_bit\_xor**(*T* &var)

The function template *reduction\_bit\_xor* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses `std::bit_xor{ }` as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction\_bit\_xor* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function,

<sup>689</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the `std::bit_xor{ }` operation until a single value remains, which is then assigned back to the live-out object.

*T* shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

---

#### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

#### Parameters

- **var** – [in,out] The live-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

#### Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of *identity*, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::bit_xor<T>> reduction_bit_xor(T &var, T
                                                                    const
                                                                    &identity)
```

## hpx::reduce

Defined in header `hpx/algorithm.hpp`<sup>690</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

<sup>690</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename ExPolicy, typename FwdIter, typename F, typename T = typename
std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, FwdIter first,
FwdIter last, T init, F &&f)
```

Returns GENERALIZED\_SUM(f, init, \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *f*.

---

---

**Note:** GENERALIZED\_SUM(op, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(op, b1, ..., bK), GENERALIZED\_SUM(op, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

### Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter, typename T = typename  
std::iterator_traits<FwdIter>::value_type>  
util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init)
```

Returns GENERALIZED\_SUM(+, init, \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the operator+().

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

### Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter>
```

```
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce(ExPolicy&&policy, FwdIter first, FwdIter last)
```

Returns GENERALIZED\_SUM(+, T(), \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the operator+().

---

---

**Note:** The type of the initial value (and the result type) *T* is determined from the *value\_type* of the used *FwdIter*.

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
-

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

### Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise (where *T* is the value\_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

```
template<typename FwdIter, typename F, typename T = typename std::iterator_traits<FwdIter>::value_type>  
T reduce(FwdIter first, FwdIter last, T init, F &&f)
```

Returns GENERALIZED\_SUM(*f*, init, \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *f*.

---

---

**Note:** GENERALIZED\_SUM(*op*, *a*1, ..., *a**N*) is defined as follows:

- *a*1 when *N* is 1
  - *op*(GENERALIZED\_SUM(*op*, *b*1, ..., *b**K*), GENERALIZED\_SUM(*op*, *b**M*, ..., *b**N*)), where:
    - *b*1, ..., *b**N* may be any permutation of *a*1, ..., *a**N* and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to any of those types.

### Returns

The *reduce* algorithm returns *T*. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

```
template<typename FwdIter, typename T = typename std::iterator_traits<FwdIter>::value_type>
T reduce(FwdIter first, FwdIter last, T init)
```

Returns GENERALIZED\_SUM(+, init, \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of *reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the operator+().

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

### Returns

The *reduce* algorithm returns a *T*. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

```
template<typename FwdIter>
std::iterator_traits<FwdIter>::value_type reduce(FwdIter first, FwdIter last)
```

Returns GENERALIZED\_SUM(+, T(), \*first, ..., \*(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the operator+().

---

---

**Note:** The type of the initial value (and the result type) *T* is determined from the value\_type of the used *FwdIter*.

---

---

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

#### Template Parameters

**FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

#### Returns

The *reduce* algorithm returns *T* (where T is the value\_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

## hpx::transform\_reduce

Defined in header [hpx/algorithm.hpp](#)<sup>691</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

---

<sup>691</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename ExPolicy, typename FwdIter, typename T, typename Reduce, typename Convert>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy &&policy, FwdIter
                                                                    first, FwdIter last, T init,
                                                                    Reduce &&red_op, Convert
                                                                    &&conv_op)
```

Returns GENERALIZED\_SUM(red\_op, init, conv\_op(\*first), ..., conv\_op(\*(first + (last - first) - 1))). Executed according to the policy.

The reduce operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform\_reduce* and *accumulate* is that the behavior of *transform\_reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *red\_op* and *conv\_op*.

---

---

**Note:** GENERALIZED\_SUM(op, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(op, b1, ..., bK), GENERALIZED\_SUM(op, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **init** – The initial value for the generalized sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv\_op* can be implicitly converted to any of those types.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

### Returns

The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel\_task\_policy* and returns *T* otherwise. The *transform\_reduce* algorithm returns the result of the generalized sum over the values returned from *conv\_op* when applied to the elements given by the input range [first, last).

```
template<typename InIter, typename T, typename Reduce, typename Convert>  
T transform_reduce(InIter first, InIter last, T init, Reduce &&red_op, Convert &&conv_op)
```

Returns GENERALIZED\_SUM(red\_op, init, conv\_op(\*first), ..., conv\_op(\*(first + (last - first) - 1))).

The difference between *transform\_reduce* and *accumulate* is that the behavior of *transform\_reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicates *red\_op* and *conv\_op*.

---

---

**Note:** GENERALIZED\_SUM(op, a1, ..., aN) is defined as follows:

- a1 when N is 1
  - op(GENERALIZED\_SUM(op, b1, ..., bK), GENERALIZED\_SUM(op, bM, ..., bN)), where:
    - b1, ..., bN may be any permutation of a1, ..., aN and
    - $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red\_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv\_op* can be implicitly converted to any of those types.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*. The type *R* must be such that an object of this type can be implicitly converted to *T*.

#### Returns

The *transform\_reduce* algorithm returns a *T*. The *transform\_reduce* algorithm returns the result of the generalized sum over the values returned from *conv\_op* when applied to the elements given by the input range [first, last).

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy &&policy,
                                                                              FwdIter1 first1, FwdIter1
                                                                              last1, FwdIter2 first2, T init)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*. Executed according to the policy.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications each of *reduce* and *transform*.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as return values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

### Returns

The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise.

```
template<typename InIter1, typename InIter2, typename T>  
T transform_reduce(InIter1 first1, InIter1 last1, InIter2 first2, T init)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications each of *reduce* and *transform*.

---

### Template Parameters

- **InIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as return values (deduced).

### Parameters

- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

**Returns**

The *transform\_reduce* algorithm returns a *T*.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Reduce,
typename Convert>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy &&policy,
                                                                    FwdIter1 first1, FwdIter1
                                                                    last1, FwdIter2 first2, T init,
                                                                    Reduce &&red_op, Convert
                                                                    &&conv_op)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*. Executed according to the policy.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform\_reduce* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications each of *reduce* and *transform*.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

- **red\_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *red\_op*.

### Returns

The *transform\_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *T* otherwise.

```
template<typename InIter1, typename InIter2, typename T, typename Reduce, typename Convert>  
T transform_reduce(ExPolicy &&policy, InIter1 first1, InIter1 last1, InIter2 first2, T init, Reduce  
                  &&red_op, Convert &&conv_op)
```

Returns the result of accumulating *init* with the inner products of the pairs formed by the elements of two ranges starting at *first1* and *first2*.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications each of *reduce* and *transform*.

---

### Template Parameters

- **InIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

### Parameters

- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

- **red\_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *conv\_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **conv\_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *red\_op*.

### Returns

The *transform\_reduce* algorithm returns a *T*.

## hpx::reverse, hpx::reverse\_copy

Defined in header `hpx/algorithm.hpp`<sup>692</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename BidirIter>
void reverse(BidirIter first, BidirIter last)
```

Reverses the order of the elements in the range `[first, last)`. Behaves as if applying `std::iter_swap` to every pair of iterators `first+i`, `(last-i) - 1` for each non-negative `i < (last-first)/2`.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

### Template Parameters

**BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

<sup>692</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

**Returns**

The *reverse* algorithm returns *void*.

```
template<typename ExPolicy, typename BidirIter>  
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, void> reverse(ExPolicy &&policy, BidirIter first,  
BidirIter last)
```

Reverses the order of the elements in the range [first, last). Behaves as if applying *std::iter\_swap* to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2. Executed according to the policy.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Linear in the distance between *first* and *last*.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The *reverse* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename BidirIter, typename OutIter>  
OutIter reverse_copy(BidirIter first, BidirIter last, OutIter dest)
```

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(dest + (last - first) - 1 - i) = *(first + i)$  once for each non-negative i < (last - first). If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel *reverse\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the begin of the destination range.

#### Returns

The *reverse\_copy* algorithm returns an *OutIter*. The *reverse\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename BidirIter, typename FwdIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> reverse_copy(ExPolicy &&policy,
                                          BidirIter first, BidirIter
                                          last, FwdIter dest)
```

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment  $*(dest + (last - first) - 1 - i) = *(first + i)$  once for each non-negative  $i < (last - first)$ . If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined. Executed according to the policy.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the begin of the destination range.

#### Returns

The *reverse\_copy* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *reverse\_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx::experimental::for\_each\_index

Defined in header [hpx/algorithm.hpp](#)<sup>693</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

### Functions

```
template<typename Mapping, typename Fun>
constexpr void for_each_index(Mapping const &mapping, Fun fun)
```

Calls *fun* with every multidimensional index in the domain of *mapping* (i.e., its extents), in sequential order.

If *fun* returns a result, the result is ignored.

The layout mapping is a hint; implementations are encouraged to choose an iteration order that performs well for the given mapping.

---

**Note:** Complexity: Applies *fun* exactly the product of all extents of *mapping* times.

---

#### Template Parameters

- **Mapping** – A type meeting the layout mapping requirements. Must expose *index\_type*, *extents\_type*, *static rank()*, and *extents()*.
- **Fun** – The type of the function/function object to use (deduced). *Fun* must meet *Copy-Constructible* and be invocable with exactly *Mapping::rank()* arguments of type *Mapping::index\_type*.

#### Parameters

- **mapping** – The layout mapping whose extents define the iteration domain.
- **fun** – Callable invoked as *fun*(*i0*, *i1*, ...) for every multidimensional index in the domain.

```
template<typename ExPolicy, typename Mapping, typename Fun>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> for_each_index(ExPolicy &&policy,
                                                                           Mapping const &mapping,
                                                                           Fun fun)
```

---

<sup>693</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

Calls *fun* with every multidimensional index in the domain of *mapping* (i.e., its extents), executed according to *policy*.

If *fun* returns a result, the result is ignored.

---

**Note:** Complexity: Applies *fun* exactly the product of all extents of *mapping* times.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced).
- **Mapping** – A type meeting the layout mapping requirements. Must meet *CopyConstructible*.
- **Fun** – The type of the function/function object to use (deduced). Must meet *CopyConstructible*.

#### Parameters

- **policy** – The execution policy to use for scheduling.
- **mapping** – The layout mapping whose extents define the iteration domain.
- **fun** – Callable invoked as `fun(i0, i1, ...)` for every multidimensional index in the domain.

#### Returns

*hpx::future<void>* if the execution policy is *sequenced\_task\_policy* or *parallel\_task\_policy*, *void* otherwise.

## hpx::experimental::reduction\_bit\_or

Defined in header `hpx/algorithm.hpp`<sup>694</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

### Functions

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::bit_or<T>> reduction_bit_or(T &var)
```

The function template *reduction\_bit\_or* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses `std::bit_or{ }` as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction\_bit\_or* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

<sup>694</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the `std::bit_or{}` operation until a single value remains, which is then assigned back to the live-out object.

`T` shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

---

#### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

#### Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

#### Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::bit_or<T>> reduction_bit_or(T &var, T
                                                                    const
                                                                    &identity)
```

### hpx::experimental::reduction

Defined in header `hpx/algorithm.hpp`<sup>695</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

---

<sup>695</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename T, typename Op>
constexpr hpx::parallel::detail::reduction_helper<T, std::decay_t<Op>> reduction(T &var, T const
&identity, Op
&&combiner)
```

The function template returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, a combiner function object, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses reduction objects by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the reduction object's combiner operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*. The expression

```
var = combiner(var, var)
```

shall be well-formed.

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation. For example if the combiner is `plus<T>`, incrementing the view would be consistent with the combiner but doubling it or assigning to it would not.

### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

### Parameters

- **var** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.
- **combiner** – [in] The binary function (object) used to perform a pairwise reduction on the elements.

### Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of *identity*, and views are combined by invoking the copy of *combiner*, passing it the two views to be combined.

```
template<typename T, typename Op>
constexpr hpx::parallel::detail::reduction_helper<T, std::decay_t<Op>> reduction(T &var, Op
&&combiner)
```

## hpx::uninitialized\_relocate, hpx::uninitialized\_relocate\_n

Defined in header [hpx/algorithm.hpp](#)<sup>696</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter1, typename InIter2, typename FwdIter>  
FwdIter uninitialized_relocate(InIter1 first, InIter2 last, FwdIter dest)
```

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized\_relocate* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: time:  $O(n)$ , space:  $O(1)$  1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, last):  $\text{std::distance}(\text{first}, \text{last}) * \text{sizeof}(T)$  bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, last):  $\text{std::distance}(\text{first}, \text{last})$  memory copies of  $\text{sizeof}(T)$  bytes each are performed. 3) For “non-trivially relocatable” underlying types (T):  $\text{std::distance}(\text{first}, \text{last})$  move assignments and destructions are performed.

---

---

**Note:** Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALY_RELOCATABLE` macros found in `<hpx/type_support/is_trivially_relocatable.hpp>`.

---

### Template Parameters

- **InIter1** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the source iterator last (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

---

<sup>696</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

**Returns**

The *uninitialized\_relocate* algorithm returns *FwdIter*. The *uninitialized\_relocate* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

```
template<typename ExPolicy, typename InIter1, typename InIter2, typename FwdIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> uninitialized_relocate(ExPolicy
                                                                                      &&policy,
                                                                                      InIter1 first,
                                                                                      InIter2 last,
                                                                                      FwdIter dest)
```

Relocates the elements in the range defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized\_relocate* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: time:  $O(n)$ , space:  $O(1)$  1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, last):  $\text{std::distance}(\text{first}, \text{last}) * \text{sizeof}(T)$  bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, last):  $\text{std::distance}(\text{first}, \text{last})$  memory copies of  $\text{sizeof}(T)$  bytes each are performed. 3) For “non-trivially relocatable” underlying types (T):  $\text{std::distance}(\text{first}, \text{last})$  move assignments and destructions are performed.

---

---

**Note:** Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in `<hpx/type_support/is_trivially_relocatable.hpp>`.

---

---

**Note:** Parallel execution requires both *first* and *dest* to be contiguous iterators. If either iterator is non-contiguous, the algorithm cannot determine whether the source and destination ranges overlap, and will silently fall back to sequential execution regardless of the execution policy provided.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **InIter1** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the source iterator last (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range. The assignments in the parallel *uninitialized\_relocate\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

#### Returns

The *uninitialized\_relocate* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_relocate* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

```
template<typename BiIter1, typename BiIter2>  
BiIter2 uninitialized_relocate_backward(BiIter1 first, BiIter1 last, BiIter2 dest_last)
```

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area ending at *dest\_last*. The objects are processed in reverse order. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized\_relocate* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: time:  $O(n)$ , space:  $O(1)$  1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, last):  $\text{std::distance}(\text{first}, \text{last}) * \text{sizeof}(T)$  bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, last):  $\text{std::distance}(\text{first}, \text{last})$  memory copies of  $\text{sizeof}(T)$  bytes each are performed. 3) For “non-trivially relocatable” underlying types (T):  $\text{std::distance}(\text{first}, \text{last})$  move assignments and destructions are performed.

---

---

**Note:** Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALY_RELOCATABLE` macros found in `<hpx/type_support/is_trivially_relocatable.hpp>`.

---

#### Template Parameters

- **BiIter1** – The type of the source range (deduced). This iterator type must meet the requirements of a Bidirectional iterator.
- **BiIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a Bidirectional iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_last** – Refers to the beginning of the destination range.

#### Returns

The *uninitialized\_relocate\_backward* algorithm returns *BiIter2*. The *uninitial-*

*ized\_relocate\_backward* algorithm returns the bidirectional iterator to the first element in the destination range.

```
template<typename ExPolicy, typename BiIter1, typename BiIter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, BiIter2> uninitialized_relocate_backward(ExPolicy
&&pol-
icy,
Bi-
Iter1
first,
Bi-
Iter1
last,
Bi-
Iter2
dest_last)
```

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area ending at *dest\_last*. The order of the relocation of the objects depends on the execution policy. If an exception is thrown during the the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized\_relocate\_backward* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Using the *uninitialized\_relocate\_backward* algorithm with the with a non-sequenced execution policy, will not guarantee the order of the relocation of the objects.

---

---

**Note:** Complexity: time: O(n), space: O(1) 1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, last): std::distance(first, last)\*sizeof(T) bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, last): std::distance(first, last) memory copies of sizeof(T) bytes each are performed. 3) For “non-trivially relocatable” underlying types (T): std::distance(first, last) move assignments and destructions are performed.

---

---

**Note:** Declare a type as “trivially relocatable” using the HPX\_DECLARE\_TRIVIALY\_RELOCATABLE macros found in <hpx/type\_support/is\_trivially\_relocatable.hpp>.

---

---

**Note:** Parallel execution requires both *first* and *dest\_last* to be contiguous iterators. If either iterator is non-contiguous, the algorithm cannot determine whether the source and destination ranges overlap, and will silently fall back to sequential execution regardless of the execution policy provided.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **BiIter1** – The type of the source range (deduced). This iterator type must meet the requirements of a Bidirectional iterator.
- **BiIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a Bidirectional iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest\_last** – Refers to the end of the destination range.

#### Returns

The *uninitialized\_relocate\_backward* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *BiIter2* otherwise. The *uninitialized\_relocate\_backward* algorithm returns the bidirectional iterator to the first element in the destination range.

```
template<typename InIter, typename Size, typename FwdIter>  
FwdIter uninitialized_relocate_n(InIter first, Size count, FwdIter dest)
```

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized\_relocate\_n* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

**Note:** Complexity: time:  $O(n)$ , space:  $O(1)$  1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, first+count):  $\text{count} * \text{sizeof}(T)$  bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, first+count):  $\text{count}$  memory copies of  $\text{sizeof}(T)$  bytes each are performed. 3) For “non-trivially relocatable” underlying types (T):  $\text{count}$  move assignments and destructions are performed.

---

---

**Note:** Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALY_RELOCATABLE` macros found in `<hpx/type_support/is_trivially_relocatable.hpp>`.

---

#### Template Parameters

- **InIter** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to relocate.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

### Returns

The *uninitialized\_relocate\_n* algorithm returns *FwdIter*. The *uninitialized\_relocate\_n* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

```
template<typename ExPolicy, typename InIter, typename Size, typename FwdIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> uninitialized_relocate_n(ExPolicy
                                                                    &&policy,
                                                                    InIter first,
                                                                    Size count,
                                                                    FwdIter
                                                                    dest)
```

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized\_relocate\_n* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized\_relocate\_n* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: time:  $O(n)$ , space:  $O(1)$  1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, first+count):  $\text{count} * \text{sizeof}(T)$  bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, first+count):  $\text{count}$  memory copies of  $\text{sizeof}(T)$  bytes each are performed. 3) For “non-trivially relocatable” underlying types (T):  $\text{count}$  move assignments and destructions are performed.

---

---

**Note:** Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALY_RELOCATABLE` macros found in `<hpx/type_support/is_trivially_relocatable.hpp>`.

---

---

**Note:** Parallel execution requires both *first* and *dest* to be contiguous iterators. If either iterator is non-contiguous, the algorithm cannot determine whether the source and destination ranges overlap, and will silently fall back to sequential execution regardless of the execution policy provided.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **InIter** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **Size** – The type of the argument specifying the number of elements to relocate.

- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

#### Returns

The *uninitialized\_relocate\_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter* otherwise. The *uninitialized\_relocate\_n* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

## hpx::experimental::reduction\_bit\_and

Defined in header [hpx/algorithm.hpp](#)<sup>697</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

### Functions

template<typename T>

constexpr *hpx::parallel::detail::reduction\_helper<T, std::bit\_and<T>>* **reduction\_bit\_and**(T &var)

The function template *reduction\_bit\_and* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses *std::bit\_and{ }* as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction\_bit\_and* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the *std::bit\_and{ }* operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

---

<sup>697</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

---

#### Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

#### Parameters

- **var** – [in,out] The live-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.

#### Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```
template<typename T>
constexpr hpx::parallel::detail::reduction_helper<T, std::bit_and<T>> reduction_bit_and(T &var, T
                                                                    const
                                                                    &iden-
                                                                    tity)
```

### hpx::set\_symmetric\_difference

Defined in header `hpx/algorithm.hpp`<sup>698</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

<sup>698</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

## Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename  
Pred = hpx::parallel::detail::less>  
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter3>::type set_symmetric_difference(ExPolicy  
                                                    &&pol-  
                                                    icy,  
                                                    FwdIter1  
                                                    first1,  
                                                    FwdIter1  
                                                    last1,  
                                                    FwdIter2  
                                                    first2,  
                                                    FwdIter2  
                                                    last2,  
                                                    FwdIter3  
                                                    dest,  
                                                    Pred  
                                                    &&op  
                                                    =  
                                                    Pred())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges *[first1, last1)* and *[first2, last2)*, but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in *[first1, last1)* and *n* times in *[first2, last2)*, it will be copied to *dest* exactly  $\text{std::abs}(m-n)$  times. If  $m > n$ , then the last  $m-n$  of those elements are copied from *[first1, last1)*, otherwise the last  $n-m$  elements are copied from *[first2, last2)*. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced\_policy*) or in a single new thread spawned from the current thread (for *sequenced\_task\_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

#### Returns

The *set\_symmetric\_difference* algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter3* otherwise. The *set\_symmetric\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred =
hpx::parallel::detail::less>
FwdIter3 set_symmetric_difference(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2,
FwdIter3 dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in either of the sorted ranges *[first1, last1)* and *[first2, last2)*, but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

If some element is found *m* times in *[first1, last1)* and *n* times in *[first2, last2)*, it will be copied to *dest* exactly `std::abs(m-n)` times. If *m*>*n*, then the last *m-n* of those elements are copied from *[first1,last1)*, otherwise the last *n-m* elements are copied from *[first2,last2)*. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most  $2 \cdot (N1 + N2 - 1)$  comparisons, where  $N1$  is the length of the first sequence and  $N2$  is the length of the second sequence.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set\_symmetric\_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

### Returns

The *set\_symmetric\_difference* algorithm returns a *FwdIter3*. The *set\_symmetric\_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**hpx::replace, hpx::replace\_if, hpx::replace\_copy, hpx::replace\_copy\_if**

Defined in header `hpx/algorithm.hpp`<sup>699</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

```
template<typename InIter, typename T = typename std::iterator_traits<InIter>::value_type>
void replace(InIter first, InIter last, T const &old_value, T const &new_value)
```

Replaces all elements satisfying specific criteria with *new\_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new\_value, when the following corresponding conditions hold: \*it == old\_value

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the old and new values to replace (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

**Returns**

The *replace* algorithm returns a *void*.

```
template<typename ExPolicy, typename FwdIter, typename T = typename
std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, void> replace(ExPolicy &&policy, FwdIter first,
                                                                    FwdIter last, T const &old_value, T
                                                                    const &new_value)
```

Replaces all elements satisfying specific criteria with *new\_value* in the range [first, last). Executed according to the policy.

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new\_value, when the following corresponding conditions hold: \*it == old\_value

---

<sup>699</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* assignments.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the old and new values to replace (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

#### Returns

The *replace* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename Iter, typename Pred, typename T = typename std::iterator_traits<Iter>::value_type>  
void replace_if(Iter first, Iter last, Pred &&pred, T const &new_value)
```

Replaces all elements satisfying specific criteria (for which predicate *pred* returns true) with *new\_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator *it* in the range [first, last) with *new\_value*, when the following corresponding conditions hold: `INVOKE(f, *it) != false`

The assignments in the parallel *replace\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

#### Template Parameters

- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).

- **T** – The type of the new values to replace (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.

#### Returns

The *replace\_if* algorithm returns *void*.

```
template<typename ExPolicy, typename FwdIter, typename Pred, typename T = typename
std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, void> replace_if(ExPolicy &&policy, FwdIter first,
FwdIter last, Pred &&pred, T
const &new_value)
```

Replaces all elements satisfying specific criteria (for which predicate *f* returns true) with *new\_value* in the range [first, last). Executed according to the policy.

Effects: Substitutes elements referred by the iterator *it* in the range [first, last) with *new\_value*, when the following corresponding conditions hold: `INVOKE(f, *it) != false`

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).

- **T** – The type of the new values to replace (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.

#### Returns

The *replace\_if* algorithm returns a `hpx::future<void>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *void* otherwise.

```
template<typename InIter, typename OutIter, typename T = typename  
std::iterator_traits<OutIter>::value_type>
```

```
OutIter replace_copy(InIter first, InIter last, OutIter dest, T const &old_value, T const &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either *new\_value* or  $*(first + (it - result))$  depending on whether the following corresponding condition holds:  $*(first + (i - result)) == old\_value$

The assignments in the parallel *replace\_copy* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the old and new values (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.
- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

#### Returns

The *replace\_copy* algorithm returns an *OutIter* The *replace\_copy* algorithm returns the Iterator to the element past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T = typename
std::iterator_traits<FwdIter2>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> replace_copy(ExPolicy &&policy,
                                          FwdIter1 first, FwdIter1
                                          last, FwdIter2 dest, T
                                          const &old_value, T const
                                          &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*. Executed according to the policy.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either *new\_value* or  $*(first + (it - result))$  depending on whether the following corresponding condition holds:  $*(first + (i - result)) == old\_value$

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

#### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the old and new values (deduced).

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

- **old\_value** – Refers to the old value of the elements to replace.
- **new\_value** – Refers to the new value to use as the replacement.

#### Returns

The *replace\_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *replace\_copy* algorithm returns the Iterator to the element past the last element copied.

```
template<typename InIter, typename OutIter, typename Pred, typename T = typename
std::iterator_traits<OutIter>::value_type>
```

```
OutIter replace_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred, T const &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either *new\_value* or *\*(first + (it - result))* depending on whether the following corresponding condition holds: *INVOKE(f, \*(first + (i - result))) != false*

The assignments in the parallel *replace\_copy\_if* algorithm execute in sequential order in the calling thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have *const&*, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.

**Returns**

The *replace\_copy\_if* algorithm returns an *OutIter*. The *replace\_copy\_if* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred, typename T =
typename std::iterator_traits<FwdIter2>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> replace_copy_if(ExPolicy &&policy,
                                          FwdIter1 first,
                                          FwdIter1 last,
                                          FwdIter2 dest, Pred
                                          &&pred, T const
                                          &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new\_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either *new\_value* or *\*(first + (it - result))* depending on whether the following corresponding condition holds: `INVOKE(f, *(first + (i - result))) != false`

The assignments in the parallel *replace\_copy\_if* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace\_copy\_if* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs exactly *last - first* applications of the predicate.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *replace\_copy\_if* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

- **new\_value** – Refers to the new value to use as the replacement.

#### Returns

The *replace\_copy\_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *replace\_copy\_if* algorithm returns the iterator to the element in the destination range, one past the last element copied.

## hpx::equal

Defined in header `hpx/algorithm.hpp`<sup>700</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1,
                                                       FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to the policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\min(\text{last1} - \text{first1}, \text{last2} - \text{first2}))$  applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses *operator==* to determine if two elements are equal.

---

#### Template Parameters

---

<sup>700</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

#### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

#### Returns

The *equal* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1,
                                                    FwdIter2 first2, FwdIter2 last2)
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\min(\text{last1} - \text{first1}, \text{last2} - \text{first2}))$  applications of the predicate `std::equal_to`.

---

---

**Note:** The two ranges are considered equal if, for every iterator  $i$  in the range  $[\text{first1}, \text{last1})$ ,  $*i$  equals  $*(\text{first2} + (i - \text{first1}))$ . This overload of `equal` uses `operator==` to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

### Returns

The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range  $[\text{first1}, \text{last1})$  does not equal the length of the range  $[\text{first2}, \text{last2})$ , it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1,
                                                    FwdIter2 first2, Pred &&op = Pred())
```

Returns true if the range  $[\text{first1}, \text{last1})$  is equal to the range starting at `first2`, and false otherwise. Executed according to policy.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity:  $O(\min(\text{last1} - \text{first1}, \text{last2} - \text{first2}))$  applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range  $[\text{first1}, \text{last1})$ , *\*i* equals  $*(\text{first2} + (i - \text{first1}))$ . This overload of `equal` uses `operator==` to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *equal* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1,
                                                       FwdIter2 first2)
```

Returns true if the range  $[\text{first1}, \text{last1})$  is equal to the range  $[\text{first2}, \text{last2})$ , and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last1 - first1* applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range  $[first1, last1)$ ,  $*i$  equals  $*(first2 + (i - first1))$ . This overload of *equal* uses `operator==` to determine if two elements are equal.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

### Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range  $[first1, last1)$  does not equal the length of the range  $[first2, last2)$ , it returns false.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if the range  $[first1, last1)$  is equal to the range  $[first2, last2)$ , and false otherwise.

---

**Note:** Complexity: At most  $\min(last1 - first1, last2 - first2)$  applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range  $[first1, last1)$ ,  $*i$  equals  $*(first2 + (i - first1))$ . This overload of *equal* uses `operator==` to determine if two elements are equal.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

### Returns

The *equal* algorithm returns a *bool*. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```
template<typename FwdIter1, typename FwdIter2>
```

```
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

---

**Note:** Complexity: At most  $\min(\text{last1} - \text{first1}, \text{last2} - \text{first2})$  applications of the predicate *std::equal\_to*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses *operator==* to determine if two elements are equal.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

### Returns

The *equal* algorithm returns a *bool*. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>  
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns true if the range [first1, last1) is equal to the range [first2, first2 + (last1 - first1)), and false otherwise.

---

**Note:** Complexity: At most *last1 - first1* applications of the predicate *op*.

---

---

**Note:** The two ranges are considered equal if, for every iterator *i* in the range [first1, last1), *\*i* equals *\*(first2 + (i - first1))*. This overload of *equal* uses operator== to determine if two elements are equal.

---

### Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::equal_to<>`

### Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

### Returns

The *equal* algorithm returns a *bool*. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

## hpx::all\_of, hpx::any\_of, hpx::none\_of

Defined in header `hpx/algorithm.hpp`<sup>701</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, bool> none_of(ExPolicy &&policy, FwdIter first, FwdIter last, F
&&f)
```

Checks if unary predicate *f* returns true for no elements in the range `[first, last)`.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

---

<sup>701</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

`bool pred(const Type &a);`

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *none\_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename InIter, typename F>  
bool none_of(InIter first, InIter last, F &&f)
```

Checks if unary predicate *f* returns true for no elements in the range [first, last).

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

#### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none\_of* requires *F* to meet the requirements of *CopyConstructible*.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

`bool pred(const Type &a);`

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

#### Returns

The *none\_of* algorithm returns a *bool*. The *none\_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F>
```

---

```
util::detail::algorithm_result_t<ExPolicy, bool> any_of(ExPolicy &&policy, FwdIter first, FwdIter last, F
&&f)
```

Checks if unary predicate *f* returns true for at least one element in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *any\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *any\_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename InIter, typename F>
bool any_of(InIter first, InIter last, F &&f)
```

Checks if unary predicate *f* returns true for at least one element in the range [first, last).

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *any\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *any\_of* algorithm returns a *bool*. The *any\_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, bool> all_of(ExPolicy &&policy, FwdIter first, FwdIter last, F
&&f)
```

Checks if unary predicate *f* returns true for all elements in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *all\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *all\_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *bool* otherwise. The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```
template<typename ExPolicy, typename InIter, typename F>
bool all_of(InIter first, InIter last, F &&f)
```

Checks if unary predicate *f* returns true for all elements in the range [first, last).

---

**Note:** Complexity: At most *last - first* applications of the predicate *f*

---

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *all\_of* requires *F* to meet the requirements of *CopyConstructible*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

### Returns

The *all\_of* algorithm returns a *bool*. The *all\_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

## hpx::exclusive\_scan

Defined in header [hpx/algorithm.hpp](#)<sup>702</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename OutIter, typename T>  
OutIter exclusive_scan(InIter first, InIter last, OutIter dest, T init)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, init, \*first, ..., \*(first + (i - result) - 1))

The reduce operations in the parallel *exclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *std::plus<T>*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.

---

<sup>702</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

**Returns**

The *exclusive\_scan* algorithm returns *OutIter*. The *exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter2> exclusive_scan(ExPolicy &&policy, FwdIter1 first,
                                                                    FwdIter1 last, FwdIter2 dest, T init)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(+, init, \*first, ..., \*(first + (i - result) - 1))

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *std::plus<T>*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
  - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, a1, ..., aK)
    - GENERALIZED\_NONCOMMUTATIVE\_SUM(+, aM, ..., aN) where  $1 < K+1 = M \leq N$ .
- 

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.

**Returns**

The *exclusive\_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename OutIter, typename T, typename Op>  
OutIter exclusive_scan(InIter first, InIter last, OutIter dest, T init, Op &&op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(binary\_op, init, \*first, ..., \*(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive\_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of the predicate *op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as:

- *a*<sub>1</sub> when *N* is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>K</sub>), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>M</sub>, ..., *a*<sub>N</sub>)) where  $1 < K+1 = M \leq N$ .
- 

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

### Returns

The *exclusive\_scan* algorithm returns *OutIter*. The *exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter2> exclusive_scan(ExPolicy &&policy, FwdIter1 first,
                                                                    FwdIter1 last, FwdIter2 dest, T init,
                                                                    Op &&op)
```

Assigns through each iterator *i* in  $[result, result + (last - first))$  the value of `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, ..., *(first + (i - result) - 1))`.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive\_scan* and *inclusive\_scan* is that *inclusive\_scan* includes the *i*th input element in the *i*th sum. If *op* is not mathematically associative, the behavior of *inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity:  $O(last - first)$  applications of the predicate *op*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

---

- *a1* when *N* is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

### Returns

The *exclusive\_scan* algorithm returns a `hpx::future<OutIter>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *OutIter* otherwise. The *exclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## hpx::transform\_inclusive\_scan

Defined in header `hpx/algorithm.hpp`<sup>703</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename InIter, typename OutIter, typename BinOp, typename UnOp>
OutIter transform_inclusive_scan(InIter first, InIter last, OutIter dest, BinOp &&binary_op, UnOp
                                &&unary_op)
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result))))`.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *binary\_op* nor *unary\_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges `[first,last)` or `[result,result + (last - first))`.

The difference between *inclusive\_scan* and *transform\_inclusive\_scan* is that *transform\_inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

<sup>703</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/algorithm.hpp>

---

**Note:** Complexity:  $O(\text{last} - \text{first})$  applications of each of *binary\_op* and *unary\_op*.

---

---

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

---

- `a1` when `N` is 1
  - `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of *binary\_op*.
- **UnOp** – The type of *unary\_op*.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Binary *FunctionObject* that will be applied in to the result of *unary\_op*, the results of other *binary\_op*, and *init* if provided.
- **unary\_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary\_op*.

### Returns

The *transform\_inclusive\_scan* algorithm returns a returns *OutIter*. The *transform\_inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename BinOp, typename UnOp>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy
                                                                                               &&policy,
                                                                                               FwdIter1
                                                                                               first,
                                                                                               FwdIter1
                                                                                               last,
                                                                                               FwdIter2
                                                                                               dest, BinOp
                                                                                               &&bi-
                                                                                               nary_op,
                                                                                               UnOp
                                                                                               &&unary_op)
```

Assigns through each iterator *i* in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result))))`. Executed according to the policy.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *binary\_op* nor *unary\_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges  $[first, last)$  or  $[result, result + (last - first))$ .

The difference between *inclusive\_scan* and *transform\_inclusive\_scan* is that *transform\_inclusive\_scan* includes the *i*th input element in the *i*th sum.

---

**Note:** Complexity:  $O(last - first)$  applications of each of *binary\_op* and *unary\_op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>N</sub>) is defined as:

- *a*<sub>1</sub> when *N* is 1
  - *op*(GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>1</sub>, ..., *a*<sub>K</sub>), GENERALIZED\_NONCOMMUTATIVE\_SUM(*op*, *a*<sub>M</sub>, ..., *a*<sub>N</sub>)) where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **BinOp** – The type of *binary\_op*.
- **UnOp** – The type of *unary\_op*.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Binary *FunctionObject* that will be applied in to the result of *unary\_op*, the results of other *binary\_op*, and *init* if provided.
- **unary\_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary\_op*.

**Returns**

The *transform\_inclusive\_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *transform\_inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename OutIter, typename BinOp, typename UnOp, typename T = typename
std::iterator_traits<InIter>::value_type>
```

```
OutIter transform_inclusive_scan(InIter first, InIter last, OutIter dest, BinOp &&binary_op, UnOp
&&unary_op, T init)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(op, init, conv(\*first), ..., conv(\*(first + (i - result)))).

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *binary\_op* nor *unary\_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive\_scan* and *transform\_inclusive\_scan* is that *transform\_inclusive\_scan* includes the *i*th input element in the *i*th sum. If *binary\_op* is not mathematically associative, the behavior of *transform\_inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity: O(last - first) applications of each of *binary\_op* and *unary\_op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aN) is defined as:

---

- a1 when N is 1
  - op(GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aK), GENERALIZED\_NONCOMMUTATIVE\_SUM(op, aM, ..., aN)) where 1 < K+1 = M <= N.
- 

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of *binary\_op*.
- **UnOp** – The type of *unary\_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

- **binary\_op** – Binary *FunctionObject* that will be applied in to the result of *unary\_op*, the results of other *binary\_op*, and *init* if provided.
- **unary\_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary\_op*.
- **init** – The initial value for the generalized sum.

#### Returns

The *transform\_inclusive\_scan* algorithm returns a returns *OutIter*. The *transform\_inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename BinOp, typename UnOp,
typename T = typename std::iterator_traits<FwdIter1>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy
                                                                                               &&policy,
                                                                                               FwdIter1
                                                                                               first,
                                                                                               FwdIter1
                                                                                               last,
                                                                                               FwdIter2
                                                                                               dest, BinOp
                                                                                               &&bi-
                                                                                               nary_op,
                                                                                               UnOp
                                                                                               &&unary_op,
                                                                                               T init)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED\_NONCOMMUTATIVE\_SUM(op, init, conv(\*first), ..., conv(\*(first + (i - result)))). Executed according to the policy.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *sequenced\_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform\_inclusive\_scan* algorithm invoked with an execution policy object of type *parallel\_policy* or *parallel\_task\_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *binary\_op* nor *unary\_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive\_scan* and *transform\_inclusive\_scan* is that *transform\_inclusive\_scan* includes the *i*th input element in the *i*th sum. If *binary\_op* is not mathematically associative, the behavior of *transform\_inclusive\_scan* may be non-deterministic.

---

**Note:** Complexity: O(last - first) applications of each of *binary\_op* and *unary\_op*.

---

---

**Note:** GENERALIZED\_NONCOMMUTATIVE\_SUM(op, a1, ..., aN) is defined as:

- a1 when N is 1

- 
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where  $1 < K+1 = M \leq N$ .
- 

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of *binary\_op*.
- **UnOp** – The type of *unary\_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary\_op** – Binary *FunctionObject* that will be applied in to the result of *unary\_op*, the results of other *binary\_op*, and *init* if provided.
- **unary\_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary\_op*.
- **init** – The initial value for the generalized sum.

### Returns

The *transform\_inclusive\_scan* algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type *sequenced\_task\_policy* or *parallel\_task\_policy* and returns *FwdIter2* otherwise. The *transform\_inclusive\_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

## asio

See *Public API* for a list of names and headers that are part of the public HPX API.

## hpx/asio/asio\_util.hpp

Defined in header hpx/asio/asio\_util.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

### Functions

bool **get\_endpoint**(std::string const &addr, std::uint16\_t port, ::asio::ip::tcp::endpoint &ep, bool force\_ipv4 = false)

std::string **get\_endpoint\_name**(::asio::ip::tcp::endpoint const &ep)

::asio::ip::tcp::endpoint **resolve\_hostname**(std::string const &hostname, std::uint16\_t port, ::asio::io\_context &io\_service, bool force\_ipv4 = false)

detail::endpoint\_iterator\_type **connect\_begin**(std::string const &address, std::uint16\_t port, ::asio::io\_context &io\_service)

template<typename **Locality**>

detail::endpoint\_iterator\_type **connect\_begin**(Locality const &loc, ::asio::io\_context &io\_service)

Returns an iterator which when dereferenced will give an endpoint suitable for a call to connect() related to this locality.

inline detail::endpoint\_iterator\_type **connect\_end**()

detail::endpoint\_iterator\_type **accept\_begin**(std::string const &address, std::uint16\_t port, ::asio::io\_context &io\_service)

template<typename **Locality**>

detail::endpoint\_iterator\_type **accept\_begin**(Locality const &loc, ::asio::io\_context &io\_service)

Returns an iterator which when dereferenced will give an endpoint suitable for a call to accept() related to this locality.

inline detail::endpoint\_iterator\_type **accept\_end**()

### assertion

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## hpx/assertion/api.hpp

Defined in header `hpx/assertion/api.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **assertion**

### Typedefs

using **assertion\_handler** = void (\*)(*hpx::source\_location* const &loc, char const \*expr, *std::string* const &msg)

The signature for an assertion handler.

### Functions

*assertion\_handler* **set\_assertion\_handler**(*assertion\_handler* handler)

Set the assertion handler to be used within a program. If the handler has been set already once, the call to this function will be ignored.

---

**Note:** This function is not thread safe

---

## HPX\_ASSERT, HPX\_ASSERT\_MSG

Defined in header `hpx/assert.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### Defines

**HPX\_ASSERT**(expr)

This macro asserts that *expr* evaluates to true.

If *expr* evaluates to false, The source location and *msg* is being printed along with the expression and additional. Afterward, the program is being aborted. The assertion handler can be customized by calling `hpx::assertion::set_assertion_handler()`.

Asserts are enabled if *HPX\_DEBUG* is set. This is the default for *CMAKE\_BUILD\_TYPE=Debug*

#### Parameters

- **expr** – The expression to assert on. This can either be an expression that's convertible to bool or a callable which returns bool
- **msg** – The optional message that is used to give further information if the assert fails. This should be convertible to a *std::string*

**HPX\_ASSERT\_MSG**(expr, msg)

See also:

HPX\_ASSERT

### HPX\_CURRENT\_SOURCE\_LOCATION, hpx::source\_location

Defined in header [hpx/source\\_location.hpp](#)<sup>704</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

#### Functions

`std::ostream &operator<<(std::ostream &os, source_location const &loc)`

### hpx/assertion/evaluate\_assert.hpp

Defined in header `hpx/assertion/evaluate_assert.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **assertion**

### async\_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx::launch

Defined in header [hpx/future.hpp](#)<sup>705</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

## Enums

enum class **launch\_policy** : *std::int8\_t*

*Values:*

enumerator **async**

enumerator **deferred**

enumerator **task**

enumerator **sync**

enumerator **fork**

enumerator **apply**

enumerator **sync\_policies**

enumerator **async\_policies**

enumerator **all**

struct **launch** : public detail::policy\_holder<>

*#include <launch\_policy.hpp>* Launch policies for *hpx::async* etc.

## Public Functions

inline constexpr **launch**() noexcept

Default constructor. This creates a launch policy representing all possible launch modes

inline constexpr **launch**(detail::async\_policy const p) noexcept

Create a launch policy representing asynchronous execution.

inline constexpr **launch**(detail::task\_policy const p) noexcept

Create a launch policy representing asynchronous execution, but disabled inline execution.

inline constexpr **launch**(detail::fork\_policy const p) noexcept

Create a launch policy representing asynchronous execution. The new thread is executed in a preferred way

inline constexpr **launch**(detail::sync\_policy const p) noexcept

Create a launch policy representing synchronous execution.

inline constexpr **launch**(detail::deferred\_policy const p) noexcept

Create a launch policy representing deferred execution.

```
inline constexpr launch(detail::apply_policy const p) noexcept
    Create a launch policy representing fire and forget execution.

template<typename F>
inline constexpr launch(detail::select_policy<F> const &p) noexcept
    Create a launch policy that is dynamically selected at runtime.

template<typename Launch>
inline constexpr launch(Launch l, threads::thread_priority const priority, threads::thread_stacksize
    const stacksize, threads::thread_schedule_hint const hint) noexcept
```

### Public Static Attributes

```
static const detail::async_policy async
    Predefined launch policy representing asynchronous execution.

static const detail::task_policy task
    Predefined launch policy representing asynchronous execution with disabled inline execution

static const detail::fork_policy fork
    Predefined launch policy representing asynchronous execution. The new thread is executed in a pre-
    ferred way

static const detail::sync_policy sync
    Predefined launch policy representing synchronous execution.

static const detail::deferred_policy deferred
    Predefined launch policy representing deferred execution.

static const detail::apply_policy apply
    Predefined launch policy representing fire and forget execution.

static const detail::select_policy_generator select
    Predefined launch policy representing delayed policy selection.
```

### hpx::sync

Defined in header [hpx/future.hpp](#)<sup>706</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

<sup>706</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

## Functions

```
template<typename F, typename ...Ts>
decltype(auto) sync(F &&f, Ts&&... ts)
```

The function template *sync* runs the function *f* synchronously and returns a *hpx::future* that will eventually hold the result of that function call.

## hpx::async

Defined in header [hpx/future.hpp](#)<sup>707</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

```
template<typename F, typename ...Ts>
decltype(auto) async(F &&f, Ts&&... ts)
```

The function template *async* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a *hpx::future* that will eventually hold the result of that function call. If no policy is defined, *async* behaves as if it is called with policy being *hpx::launch::async* | *hpx::launch::deferred*. Otherwise, it calls a function *f* with arguments *ts* according to a specific launch policy.

- If the *async* flag is set (i.e. `(policy & hpx::launch::async) != 0`), then *async* executes the callable object *f* on a new thread of execution (with all thread-locals initialized) as if spawned by `hpx::thread(std::forward<F>(f), std::forward<Ts>(ts)...)` , except that if the function *f* returns a value or throws an exception, it is stored in the shared state accessible through the *hpx::future* that *async* returns to the caller.
- If the *deferred* flag is set (i.e. `(policy & hpx::launch::deferred) != 0`), then *async* converts *f* and *ts...* the same way as by *hpx::thread* constructor, but does not spawn a new thread of execution. Instead, lazy evaluation is performed: the first call to a non-timed wait function on the *hpx::future* that *async* returned to the caller will cause the copy of *f* to be invoked (as a rvalue) with the copies of *ts...* (also passed as rvalues) in the current thread (which does not have to be the thread that originally called *hpx::async*). The result or exception is placed in the shared state associated with the future and only then it is made ready. All further accesses to the same *hpx::future* will return the result immediately.
- If neither *hpx::launch::async* nor *hpx::launch::deferred*, nor any implementation-defined policy flag is set in policy, the behavior is undefined.

If more than one flag is set, it is implementation-defined which policy is selected. For the default (both the *hpx::launch::async* and *hpx::launch::deferred* flags are set in policy), standard recommends (but doesn't require) utilizing available concurrency, and deferring any additional tasks.

In any case, the call to *hpx::async* synchronizes-with (as defined in `std::memory_order`) the call to *f*, and the completion of *f* is sequenced-before making the shared state ready. If the *async* policy is chosen, the associated thread completion synchronizes-with the successful return from the first function that is waiting on the shared state, or with the return of the last function that releases the shared state, whichever comes first. If `std::decay<Function>::type` or each type in `std::decay<Ts>::type` is not constructible from its corresponding argument, the program is ill-formed.

<sup>707</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

**Parameters**

- **f** – Callable object to call
- **ts** – parameters to pass to **f**

**Returns**

`hpx::future` referring to the shared state created by this call to `hpx::async`.

**hpx::dataflow**

Defined in header `hpx/future.hpp`<sup>708</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

```
template<typename F, typename ...Ts>
decltype(auto) dataflow(F &&f, Ts&&... ts)
```

The function template *dataflow* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a `hpx::future` that will eventually hold the result of that function call. Its behavior is similar to `hpx::async` with the exception that if one of the arguments is a *future*, then `hpx::dataflow` will wait for the *future* to be ready to launch the thread. Hence, the operation is delayed until all the arguments are ready.

**hpx::post**

Defined in header `hpx/future.hpp`<sup>709</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

```
template<typename F, typename ...Ts>
bool post(F &&f, Ts&&... ts)
```

Runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool). This is done in a fire-and-forget manner, meaning there is no return value or way to synchronize with the function execution (it does not return an `hpx::future` that would hold the result of that function call).

`hpx::post` is particularly useful when synchronization mechanisms as heavyweight as futures are not desired, and instead, more lightweight mechanisms like latches or atomic variables are preferred. Essentially, the *post* function enables the launch of a new thread without the overhead of creating a future.

---

**Note:** `hpx::post` is similar to `hpx::async` but does not return a future. This is why there is no way of finding out the result/failure of the execution of this function.

---

---

<sup>708</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

<sup>709</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

## async\_combinators

See *Public API* for a list of names and headers that are part of the public HPX API.

### hpx::wait\_any

Defined in header `hpx/future.hpp`<sup>710</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

### Functions

```
template<typename InputIter>
void wait_any(InputIter first, InputIter last)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

---

#### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_any* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_any* should wait.

```
template<typename R>
void wait_any(std::vector<future<R>> &futures)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

---

<sup>710</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

**Parameters**

**futures** – [in] A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_any* should wait.

```
template<typename R, std::size_t N>  
void wait_any(std::array<future<R>, N> &futures)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

---

**Parameters**

**futures** – [in] Amn array holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_any* should wait.

```
template<typename ...T>  
void wait_any(T&&... futures)
```

The function *wait\_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any* returns after at least one future has become ready. All input futures are still valid after *wait\_any* returns.

---

---

**Note:** The function *wait\_any* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_nothrow* instead.

---

**Parameters**

**futures** – [in] An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_any* should wait.

```
template<typename InputIter>  
void wait_any_n(InputIter first, std::size_t count)
```

The function *wait\_any\_n* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

---

**Note:** The function *wait\_any\_n* returns after at least one future has become ready. All input futures are still valid after *wait\_any\_n* returns.

---

---

**Note:** The function *wait\_any\_n* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_any\_n\_nothrow* instead.

---

### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_any\_n* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

### hpx::when\_some

Defined in header [hpx/future.hpp](#)<sup>711</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

### Functions

```
template<typename InputIter, typename Container = vector<future<typename
std::iterator_traits<InputIter>::value_type>>>
future<when_some_result<Container>> when_some(std::size_t n, Iterator first, Iterator last)
```

The function *when\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The future returned by the function *when\_some* becomes ready when at least *n* argument futures have become ready.

---

---

**Note:** Calling this version of *when\_some* where *first* == *last*, returns a future with an empty container that is immediately ready. Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_some* will not throw an exception, but the futures held in the output collection may.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.

### Returns

Returns a *when\_some\_result* holding the same list of futures as has been passed to *when\_some* and indices pointing to ready futures.

- `future<when_some_result<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

---

<sup>711</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

```
template<typename Range>
future<when_some_result<Range>> when_some(std::size_t n, Range &&futures)
```

The function *when\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The future returned by the function *when\_some* becomes ready when at least *n* argument futures have become ready.

---

---

**Note:** Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_some* will not throw an exception, but the futures held in the output collection may.

---

#### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] A container holding an arbitrary amount of *future* or *shared\_future* objects for which *when\_some* should wait.

#### Returns

Returns a *when\_some\_result* holding the same list of futures as has been passed to *when\_some* and indices pointing to ready futures.

- *future<when\_some\_result<Container<future<R>>>>*: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

```
template<typename ...Ts>
future<when_some_result<tuple<future<T>...>>> when_some(std::size_t n, Ts&&... futures)
```

The function *when\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The future returned by the function *when\_some* becomes ready when at least *n* argument futures have become ready.

---

---

**Note:** Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_some* will not throw an exception, but the futures held in the output collection may.

---

#### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *when\_some* should wait.

**Returns**

Returns a *when\_some\_result* holding the same list of futures as has been passed to *when\_some* and an index pointing to a ready future..

- `future<when_some_result<tuple<future<T0>, future<T1>...>>>`: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- `future<when_some_result<tuple<>>>` if *when\_some* is called with zero arguments. The returned future will be initially ready.

```
template<typename InputIter, typename Container = vector<future<typename
std::iterator_traits<InputIter>::value_type>>>
future<when_some_result<Container>> when_some_n(std::size_t n, Iterator first, std::size_t count)
```

The function *when\_some\_n* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The future returned by the function *when\_some\_n* becomes ready when at least *n* argument futures have become ready.

---

---

**Note:** Calling this version of *when\_some\_n* where *count* == 0, returns a future with the same elements as the arguments that is immediately ready. Possibly none of the futures in that container are ready. Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_some\_n* will not throw an exception, but the futures held in the output collection may.

---

**Parameters**

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

**Returns**

Returns a *when\_some\_result* holding the same list of futures as has been passed to *when\_some* and indices pointing to ready futures.

- `future<when_some_result<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

```
template<typename Sequence>
```

```
struct when_some_result
```

*#include <when\_some.hpp>* Result type for *when\_some*, contains a sequence of futures and indices pointing to ready futures.

## Public Members

`std::vector<std::size_t>` **indices**

List of indices of futures that have become ready.

Sequence **futures**

The sequence of futures as passed to `hpx::when_some`.

## `hpx::when_all`

Defined in header `hpx/future.hpp`<sup>712</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

## Functions

template<typename **InputIter**, typename **Container** = vector<future<typename  
`std::iterator_traits<InputIter>::value_type>>>`

`hpx::future<Container>` **when\_all**(*InputIter* first, *InputIter* last)

function *when\_all* creates a future object that becomes ready when all elements in a set of *future* and *shared\_future* objects become ready. It is an operator allowing to join on the result of all given futures. It AND-composes all given future objects and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** Calling this version of *when\_all* where `first == last`, returns a future with an empty container that is immediately ready. Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_all* will not throw an exception, but the futures held in the output collection may.

---

## Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.

## Returns

Returns a future holding the same list of futures as has been passed to *when\_all*.

- `future<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename **Range**>

---

<sup>712</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

*hpx::future<Range>* **when\_all**(*Range* &&values)

function *when\_all* creates a future object that becomes ready when all elements in a set of *future* and *shared\_future* objects become ready. It is an operator allowing to join on the result of all given futures. It AND-composes all given future objects and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** Calling this version of *when\_all* where the input container is empty, returns a future with an empty container that is immediately ready. Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_all* will not throw an exception, but the futures held in the output collection may.

---

#### Parameters

**values** – [in] A range holding an arbitrary amount of *future* or *shared\_future* objects for which *when\_all* should wait.

#### Returns

Returns a future holding the same list of futures as has been passed to *when\_all*.

- *future<Container<future<R>>>*: If the input cardinality is unknown at compile time and the futures are all have the same type.

template<typename ...T>

*hpx::future<hpx::tuple<hpx::future<T>...>>* **when\_all**(*T*&&... futures)

function *when\_all* creates a future object that becomes ready when all elements in a set of *future* and *shared\_future* objects become ready. It is an operator allowing to join on the result of all given futures. It AND-composes all given future objects and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** Each future and *shared\_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when\_all* will not throw an exception, but the futures held in the output collection may.

---

#### Parameters

**futures** – [in] An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *when\_all* should wait.

#### Returns

Returns a future holding the same list of futures as has been passed to *when\_all*.

- *future<tuple<future<T0>, future<T1>, future<T2>...>>*: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- *future<tuple<>>* if *when\_all* is called with zero arguments. The returned future will be initially ready.

template<typename **InputIter**, typename **Container** = vector<*future*<typename *std::iterator\_traits<InputIter>::value\_type>>>*

*hpx::future<Container>* **when\_all\_n**(*InputIter* begin, *std::size\_t* count)

function *when\_all* creates a future object that becomes ready when all elements in a set of *future* and *shared\_future* objects become ready. It is an operator allowing to join on the result of all given futures. It AND-composes all given future objects and returns a new future object representing the same list of futures after they finished executing.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

---

**Note:** None of the futures in the input sequence are invalidated.

---

### Parameters

- **begin** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_all\_n* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

### Throws

This – function will throw errors which are encountered while setting up the requested operation only. Errors encountered while executing the operations delivering the results to be stored in the futures are reported through the futures themselves.

### Returns

Returns a future holding the same list of futures as has been passed to *when\_all\_n*.

- `future<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output vector will be the same as given by the input iterator.

## hpx::when\_any

Defined in header `hpx/future.hpp`<sup>713</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

### Functions

```
template<typename InputIter, typename Container = vector<future<typename  
std::iterator_traits<InputIter>::value_type>>>
```

```
future<when_any_result<Container>> when_any(InputIter first, InputIter last)
```

function *when\_any* creates a future object that becomes when at least one element in a set of *future* and *shared\_future* objects becomes ready. It is a non-deterministic choice operator. It OR-composes all given future objects and returns a new future object representing the same list of futures after one future of that list finishes execution.

### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_any* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_any* should wait.

---

<sup>713</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

**Returns**

Returns a *when\_any\_result* holding the same list of futures as has been passed to *when\_any* and an index pointing to a ready future.

- `future<when_any_result<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output container will be the same as given by the input iterator.

```
template<typename Range>
```

```
future<when_any_result<Range>> when_any(Range &values)
```

function *when\_any* creates a future object that becomes when at least one element in a set of *future* and *shared\_future* objects becomes ready. It is a non-deterministic choice operator. It OR-composes all given future objects and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Parameters**

**values** – [in] A range holding an arbitrary amount of *futures* or *shared\_future* objects for which *when\_any* should wait.

**Returns**

Returns a *when\_any\_result* holding the same list of futures as has been passed to *when\_any* and an index pointing to a ready future.

- `future<when_any_result<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output container will be the same as given by the input iterator.

```
template<typename ...T>
```

```
future<when_any_result<tuple<future<T>...>>> when_any(T&&... futures)
```

function *when\_any* creates a future object that becomes when at least one element in a set of *future* and *shared\_future* objects becomes ready. It is a non-deterministic choice operator. It OR-composes all given future objects and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Parameters**

**futures** – [in] An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *when\_any* should wait.

**Returns**

Returns a *when\_any\_result* holding the same list of futures as has been passed to *when\_any* and an index pointing to a ready future.

- `future<when_any_result<tuple<future<T0>, future<T1>...>>>`: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- `future<when_any_result<tuple<>>>` if *when\_any* is called with zero arguments. The returned future will be initially ready.

```
template<typename InputIter, typename Container = vector<future<typename  
std::iterator_traits<InputIter>::value_type>>>
```

```
future<when_any_result<Container>> when_any_n(InputIter first, std::size_t count)
```

function *when\_any\_n* creates a future object that becomes when at least one element in a set of *future* and *shared\_future* objects becomes ready. It is a non-deterministic choice operator. It OR-composes all given future objects and returns a new future object representing the same list of futures after one future of that list finishes execution.

---

**Note:** None of the futures in the input sequence are invalidated.

---

### Parameters

- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_any\_n* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

### Returns

Returns a *when\_any\_result* holding the same list of futures as has been passed to *when\_any* and an index pointing to a ready future.

- `future<when_any_result<Container<future<R>>>>>`: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output container will be the same as given by the input iterator.

```
template<typename Sequence>
```

```
struct when_any_result
```

*#include <when\_any.hpp>* Result type for *when\_any*, contains a sequence of futures and an index pointing to a ready future.

### Public Members

`std::size_t` **index**

The index of a future which has become ready.

*Sequence* **futures**

The sequence of futures as passed to `hpx::when_any`

### `hpx::wait_some`

Defined in header `hpx/future.hpp`<sup>714</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

---

<sup>714</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

## Functions

```
template<typename InputIter>
void wait_some(std::size_t n, InputIter first, InputIter last)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_some* returns after *n* futures have become ready. All input futures are still valid after *wait\_some* returns.

---

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the function to return.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.

```
template<typename R>
void wait_some(std::size_t n, std::vector<future<R>> &&futures)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_some* returns after *n* futures have become ready. All input futures are still valid after *wait\_some* returns.

---

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_some* should wait.

```
template<typename R, std::size_t N>
void wait_some(std::size_t n, std::array<future<R>, N> &&futures)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_some* returns after *n* futures have become ready. All input futures are still valid after *wait\_some* returns.

---

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

#### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] An array holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_some* should wait.

```
template<typename ...T>
void wait_some(std::size_t n, T&&... futures)
```

The function *wait\_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_all* returns after *n* futures have become ready. All input futures are still valid after *wait\_some* returns.

---

---

**Note:** The function *wait\_some* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_some\_nothrow* instead.

---

#### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures** – [in] An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_some* should wait.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
template<typename InputIter>
void wait_some_n(std::size_t n, InputIter first, std::size_t count)
```

The function *wait\_some\_n* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after *n* of them finished executing.

---

**Note:** The function *wait\_some\_n* returns after *n* futures have become ready. All input futures are still valid after *wait\_some\_n* returns.

---

---

**Note:** The function `wait_some_n` will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use `wait_some_n_nothrow` instead.

---

### Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *when\_all* should wait.
- **count** – [in] The number of elements in the sequence starting at *first*.

## hpx::wait\_each

Defined in header `hpx/future.hpp`<sup>715</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

### Functions

```
template<typename F, typename Future>
void wait_each(F &&f, std::vector<Future> &&futures)
```

The function *wait\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait\_each* returns after all futures have been become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that `std::size_t` is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_each* should wait.

```
template<typename F, typename Iterator>
void wait_each(F &&f, Iterator begin, Iterator end)
```

The function *wait\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called

---

<sup>715</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

for each of the passed futures as soon as the future has become ready. *wait\_each* returns after all futures have been become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

#### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.
- **end** – The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.

```
template<typename F, typename ...T>  
void wait_each(F &&f, T&&... futures)
```

The function *wait\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait\_each* returns after all futures have been become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

#### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_each* should wait.

```
template<typename F, typename Iterator>  
void wait_each_n(F &&f, Iterator begin, std::size_t count)
```

The function *wait\_each* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

#### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each\_n* should wait.
- **count** – The number of elements in the sequence starting at *first*.

## hpx::wait\_all

Defined in header [hpx/future.hpp](#)<sup>716</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

### Functions

```
template<typename InputIter>
void wait_all(InputIter first, InputIter last)
```

The function *wait\_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function *wait\_all* returns after all futures have become ready. All input futures are still valid after *wait\_all* returns.

---

---

**Note:** The function *wait\_all* will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait\_all\_nothrow* instead.

---

### Parameters

- **first** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_all* should wait.
- **last** – The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_all* should wait.

```
template<typename R>
void wait_all(std::vector<future<R>> &&futures)
```

The function *wait\_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function *wait\_all* returns after all futures have become ready. All input futures are still valid after *wait\_all* returns.

---

<sup>716</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

---

**Note:** The function `wait_all` will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use `wait_all_nothrow` instead.

---

#### Parameters

**futures** – A vector or array holding an arbitrary amount of *future* or *shared\_future* objects for which `wait_all` should wait.

```
template<typename R, std::size_t N>
void wait_all(std::array<future<R>, N> &&futures)
```

The function `wait_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function `wait_all` returns after all futures have become ready. All input futures are still valid after `wait_all` returns.

---

---

**Note:** The function `wait_all` will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use `wait_all_nothrow` instead.

---

#### Parameters

**futures** – A vector or array holding an arbitrary amount of *future* or *shared\_future* objects for which `wait_all` should wait.

```
template<typename T>
void wait_all(hpx::future<T> const &f)
```

The function `wait_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function `wait_all` returns after the future has become ready. The input future is still valid after `wait_all` returns.

---

---

**Note:** The function `wait_all` will rethrow any exceptions captured by the future while becoming ready. If this behavior is undesirable, use `wait_all_nothrow` instead.

---

#### Parameters

**f** – A *future* or *shared\_future* for which `wait_all` should wait.

```
template<typename ...T>
void wait_all(T&&... futures)
```

The function `wait_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function `wait_all` returns after all futures have become ready. All input futures are still valid after `wait_all` returns.

---

---

**Note:** The function `wait_all` will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use `wait_all_nothrow` instead.

---

#### Parameters

**futures** – An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which `wait_all` should wait.

```
template<typename InputIter>
void wait_all_n(InputIter begin, std::size_t count)
```

The function `wait_all_n` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

---

**Note:** The function `wait_all_n` returns after all futures have become ready. All input futures are still valid after `wait_all_n` returns.

---

---

**Note:** The function `wait_all_n` will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use `wait_all_n_nothrow` instead.

---

#### Parameters

- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which `wait_all_n` should wait.
- **count** – The number of elements in the sequence starting at *first*.

#### Returns

The function `wait_all_n` will return an iterator referring to the first element in the input sequence after the last processed element.

## hpx/async\_combinators/split\_future.hpp

Defined in header `hpx/async_combinators/split_future.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

### Functions

```
template<typename ...Ts>
inline tuple<future<Ts>...> split_future(future<tuple<Ts...>> &&f)
```

The function `split_future` is an operator allowing to split a given future of a sequence of values (any tuple, `std::pair`, or `std::array`) into an equivalent container of futures where each future represents one of the values from the original future. In some sense this function provides the inverse operation of `when_all`.

---

**Note:** The following cases are special:

```
tuple<future<void> > split_future(future<tuple<> > && f);  
array<future<void>, 1> split_future(future<array<T, 0> > && f);
```

here the returned futures are directly representing the futures which were passed to the function.

---

#### Parameters

**f** – [in] A future holding an arbitrary sequence of values stored in a tuple-like container. This facility supports *hpx::tuple<>*, *std::pair<T1, T2>*, and *std::array<T, N>*

#### Returns

Returns an equivalent container (same container type as passed as the argument) of futures, where each future refers to the corresponding value in the input parameter. All the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

```
template<typename T>  
inline std::vector<future<T>> split_future(future<std::vector<T>> &&f, std::size_t size)
```

The function *split\_future* is an operator allowing to split a given future of a sequence of values (any *std::vector*) into a *std::vector* of futures where each future represents one of the values from the original *std::vector*. In some sense this function provides the inverse operation of *when\_all*.

#### Parameters

- **f** – [in] A future holding an arbitrary sequence of values stored in a *std::vector*.
- **size** – [in] The number of elements the vector will hold once the input future has become ready

#### Returns

Returns a *std::vector* of futures, where each future refers to the corresponding value in the input parameter. All the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

## hpx::when\_each

Defined in header [hpx/future.hpp](#)<sup>717</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

---

<sup>717</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

## Functions

```
template<typename F, typename Future>
future<void> when_each(F &&f, std::vector<Future> &&futures)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – A vector holding an arbitrary amount of *future* or *shared\_future* objects for which *wait\_each* should wait.

### Returns

Returns a future representing the event of all input futures being ready.

```
template<typename F, typename Iterator>
future<Iterator> when_each(F &&f, Iterator begin, Iterator end)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.
- **end** – The iterator pointing to the last element of a sequence of *future* or *shared\_future* objects for which *wait\_each* should wait.

### Returns

Returns a future representing the event of all input futures being ready.

```
template<typename F, typename ...Ts>
future<void> when_each(F &&f, Ts&&... futures)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

#### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – An arbitrary number of *future* or *shared\_future* objects, possibly holding different types for which *wait\_each* should wait.

#### Returns

Returns a future representing the event of all input futures being ready.

```
template<typename F, typename Iterator>  
future<Iterator> when_each_n(F &&f, Iterator begin, std::size_t count)
```

The function *when\_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

---

**Note:** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size\_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

#### Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **begin** – The iterator pointing to the first element of a sequence of *future* or *shared\_future* objects for which *wait\_each\_n* should wait.
- **count** – The number of elements in the sequence starting at *first*.

#### Returns

Returns a future holding the iterator pointing to the first element after the last one.

### async\_cuda

## Functions

```
template<typename Executor, typename ...Ts>
decltype(auto) async(Executor &&exec, hpx::sycl::experimental::sycl_executor::queue_function_ptr_t<Ts...>
&&f, Ts&&... ts)
```

`hpx::async` overload for launching `sycl` queue member functions with an `sycl` executor

```
template<typename Executor, typename ...Ts>
bool apply(Executor &&exec, hpx::sycl::experimental::sycl_executor::queue_function_ptr_t<Ts...> &&f,
Ts&&... ts)
```

`hpx::apply` overload for launching `sycl` queue member functions with an `sycl` executor

namespace **execution**

namespace **experimental**

namespace **sycl**

namespace **experimental**

struct **sycl\_executor**

## Public Types

using **future\_type** = *hpx::future*<void>

template<typename ...**Params**>

using **queue\_function\_ptr\_t** = ::sycl::event  
 (::sycl::queue::\*)(*std::conditional\_t*<*std::is\_trivial\_v*<*std::remove\_reference\_t*<*Params*>>, *std::decay\_t*<*Params*>, *Params*>...)

Default Implementation without the extra intel code\_location parameter. Removes the reference for trivial types to make the function matching easier (see *sycl\_stream.cpp* test)

## Public Functions

template<typename **sycl\_device\_selector**>

inline explicit **sycl\_executor**(*sycl\_device\_selector* const &selector)

Create a SYCL executor (based on a sycl queue)

**~sycl\_executor**() = default

inline *future\_type* **get\_future**()

Get future for this command\_queue (NOTE will be more efficient if an event is provided &#8212; otherwise a dummy kernel must be submitted to get an event)

inline *future\_type* **get\_future**(::sycl::event event)

Get future for that becomes ready when the given event completes.

template<typename ...**Params**>

inline void **post**(*queue\_function\_ptr\_t*<*Params*...> &&queue\_member\_function, *Params*&&... args)

Invoke queue member function given queue and parameters &#8212; do not use event to return a *hpx::future* (One way)

template<typename ...**Params**>

inline *hpx::future*<void> **async\_execute**(*queue\_function\_ptr\_t*<*Params*...> &&queue\_member\_function, *Params*&&... args)

Invoke queue member function given queue and parameters &#8212; *hpx::future* tied to the sycl event / (two way)

inline ::sycl::device **get\_device**() const

Return the device used by the underlying SYCL queue.

inline ::sycl::context **get\_context**() const

Return the context used by the underlying SYCL queue.

inline ::sycl::queue &**get\_queue**()

Return the underlying queue for direct access.

## Protected Attributes

`::sycl::queue` **command\_queue**

## cache

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/cache/local\_cache.hpp

Defined in header `hpx/cache/local_cache.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **cache**

```
template<typename Key, typename Entry, typename UpdatePolicy = std::less<Entry>, typename
InsertPolicy = policies::always<Entry>, typename CacheStorage = std::map<Key, Entry>,
typename Statistics = statistics::no_statistics>
class local_cache
```

*#include <hpx/cache/local\_cache.hpp>* The `local_cache` implements the basic functionality needed for a local (non-distributed) cache.

#### Template Parameters

- **Key** – The type of the keys to use to identify the entries stored in the cache
- **Entry** – The type of the items to be held in the cache, must model the `CacheEntry` concept
- **UpdatePolicy** – A (optional) type specifying a (binary) function object used to sort the cache entries based on their ‘age’. The ‘oldest’ entries (according to this sorting criteria) will be discarded first if the maximum capacity of the cache is reached. The default is `std::less<Entry>`. The function object will be invoked using 2 entry instances of the type `Entry`. This type must model the `UpdatePolicy` model.
- **InsertPolicy** – A (optional) type specifying a (unary) function object used to allow global decisions whether a particular entry should be added to the cache or not. The default is `policies::always`, imposing no global insert related criteria on the cache. The function object will be invoked using the entry instance to be inserted into the cache. This type must model the `InsertPolicy` model.
- **CacheStorage** – A (optional) container type used to store the cache items. The container must be an associative and STL compatible container. The default is a `std::map<Key, Entry>`.
- **Statistics** – A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the `CacheStatistics` concept. The default value is the type `statistics::no_statistics` which does not collect any numbers, but provides empty stubs allowing the code to compile.

## Public Types

```
using key_type = Key

using entry_type = Entry

using update_policy_type = UpdatePolicy

using insert_policy_type = InsertPolicy

using storage_type = CacheStorage

using statistics_type = Statistics

using value_type = typename entry_type::value_type

using size_type = typename storage_type::size_type

using storage_value_type = typename storage_type::value_type
```

## Public Functions

```
inline explicit local_cache(size_type max_size = 0, update_policy_type const &up =
    update_policy_type(), insert_policy_type const &ip =
    insert_policy_type())
```

Construct an instance of a *local\_cache*.

### Parameters

- **max\_size** – [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry's *get\_size* function.
- **up** – [in] An instance of the *UpdatePolicy* to use for this cache. The default is to use a default constructed instance of the type as defined by the *UpdatePolicy* template parameter.
- **ip** – [in] An instance of the *InsertPolicy* to use for this cache. The default is to use a default constructed instance of the type as defined by the *InsertPolicy* template parameter.

```
local_cache(local_cache const &other) = default
```

```
local_cache(local_cache &&other) = default
```

```
local_cache &operator=(local_cache const &other) = default
```

```
local_cache &operator=(local_cache &&other) = default
```

```
~local_cache() = default
```

inline constexpr *size\_type* **size**() const noexcept

Return current size of the cache.

**Returns**

The current size of this cache instance.

inline constexpr *size\_type* **capacity**() const noexcept

Access the maximum size the cache is allowed to grow to.

---

**Note:** The unit of this value is usually determined by the unit of the return values of the entry's function *entry::get\_size*.

---

**Returns**

The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

inline bool **reserve**(*size\_type* max\_size)

Change the maximum size this cache can grow to.

**Parameters**

**max\_size** – [in] The new maximum size this cache will be allowed to grow to.

**Returns**

This function returns *true* if successful. It returns *false* if the new *max\_size* is smaller than the current limit and the cache could not be shrunk to the new maximum size.

inline bool **holds\_key**(*key\_type* const &k) const

Check whether the cache currently holds an entry identified by the given key.

---

**Note:** This function does not call the entry's function *entry::touch*. It just checks if the cache contains an entry corresponding to the given key.

---

**Parameters**

**k** – [in] The key for the entry which should be looked up in the cache.

**Returns**

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **get\_entry**(*key\_type* const &k, *key\_type* &realkey, *entry\_type* &val)

Get a specific entry identified by the given key.

---

**Note:** The function will call the entry's *entry::touch* function if the value corresponding to the provided key is found in the cache.

---

**Parameters**

- **k** – [in] The key for the entry which should be retrieved from the cache.
- **realkey[out]** – Return the full real key found in the cache
- **val** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

**Returns**

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **get\_entry**(*key\_type* const &k, *entry\_type* &val)

Get a specific entry identified by the given key.

---

**Note:** The function will call the entry's `entry::touch` function if the value corresponding to the provided key is found in the cache.

---

#### Parameters

- **k** – [in] The key for the entry which should be retrieved from the cache.
- **val** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

#### Returns

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
inline bool get_entry(key_type const &k, value_type &val)
```

Get a specific entry identified by the given key.

---

**Note:** The function will call the entry's `entry::touch` function if the value corresponding to the provided is found in the cache.

---

#### Parameters

- **k** – [in] The key for the entry which should be retrieved from the cache
- **val** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding value.

#### Returns

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
inline bool insert(key_type const &k, value_type const &val)
```

Insert a new element into this cache.

---

**Note:** This function invokes both, the insert policy as provided to the constructor and the function `entry::insert` of the newly constructed entry instance. If either of these functions returns false the key/value pair doesn't get inserted into the cache and the `insert` function will return *false*. Other reasons for this function to fail (return *false*) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

---

#### Parameters

- **k** – [in] The key for the entry which should be added to the cache.
- **val** – [in] The value which should be added to the cache.

#### Returns

This function returns *true* if the entry has been successfully added to the cache, otherwise it returns *false*.

```
inline bool insert(key_type const &k, value_type &&val)
```

```
template<typename Entry_, std::enable_if_t<std::is_convertible_v<std::decay_t<Entry_>, entry_type>, int> = 0>
```

```
inline bool insert(key_type const &k, Entry_ &&e)
```

Insert a new entry into this cache.

---

**Note:** This function invokes both, the insert policy as provided to the constructor and the function `entry::insert` of the provided entry instance. If either of these functions returns false

the key/value pair doesn't get inserted into the cache and the *insert* function will return *false*. Other reasons for this function to fail (return *false*) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

---

**Parameters**

- **k** – [in] The key for the entry which should be added to the cache.
- **e** – [in] The entry which should be added to the cache.

**Returns**

This function returns *true* if the entry has been successfully added to the cache, otherwise it returns *false*.

```
template<typename Value, std::enable_if_t<std::is_convertible_v<std::decay_t<Value>, value_type>, int> = 0>
```

```
inline bool update(key_type const &k, Value &&val)
```

Update an existing element in this cache.

---

**Note:** The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

---

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

---

**Parameters**

- **k** – [in] The key for the value which should be updated in the cache.
- **val** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

**Returns**

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename F, typename Value, typename =  
std::enable_if_t<std::is_convertible_v<std::decay_t<Value>, value_type>>>
```

```
inline bool update_if(key_type const &k, Value &&val, F &&f)
```

Update an existing element in this cache.

---

**Note:** The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

---

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

---

**Parameters**

- **k** – [in] The key for the value which should be updated in the cache.
- **val** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

- **f** – [in] A callable taking two arguments, *k* and the key found in the cache (in that order). If *f* returns true, then the update will continue. If *f* returns false, then the update will not succeed.

**Returns**

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename Entry_, std::enable_if_t<std::is_convertible_v<std::decay_t<Entry_>,
entry_type>, int> = 0>
inline bool update(key_type const &k, Entry_ &&e)
```

Update an existing entry in this cache.

---

**Note:** The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

---

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the whole cache entry, while the other overload replaces the cached value only, leaving the cache entry properties untouched.

---

**Parameters**

- **k** – [in] The key for the entry which should be updated in the cache.
- **e** – [in] The entry which should be used as a replacement for the existing entry in the cache. Any existing entry is first removed and then this entry is added.

**Returns**

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename Func = policies::always<storage_value_type>>
inline size_type erase(Func &&ep = Func())
```

Remove stored entries from the cache for which the supplied function object returns true.

**Parameters**

**ep** – [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is *true*. Even then the entry might not be removed from the cache as its *entry::remove* function might return false.

**Returns**

This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get\_size* functions of the removed entries).

```
inline size_type erase()
```

Remove all stored entries from the cache.

---

**Note:** All entries are considered for removal, but in the end an entry might not be removed from the cache as its *entry::remove* function might return false. This function is very useful for instance in conjunction with an entry's *entry::remove* function enforcing additional criteria like entry expiration, etc.

---

**Returns**

This function returns the overall size of the removed entries (which is the sum of the

values returned by the *entry::get\_size* functions of the removed entries).

inline void **clear**()

Clear the cache.

Unconditionally removes all stored entries from the cache.

inline constexpr *statistics\_type* const &**get\_statistics**() const noexcept

Allow to access the embedded statistics instance.

#### Returns

This function returns a reference to the statistics instance embedded inside this cache

inline *statistics\_type* &**get\_statistics**() noexcept

## Protected Functions

## hpx/cache/lru\_cache.hpp

Defined in header `hpx/cache/lru_cache.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace util
```

```
        namespace cache
```

```
            template<typename Key, typename Entry, typename Statistics = statistics::no_statistics>
```

```
            class lru_cache
```

*#include <hpx/cache/lru\_cache.hpp>* The `lru_cache` implements the basic functionality needed for a local (non-distributed) LRU cache.

#### Template Parameters

- **Key** – The type of the keys to use to identify the entries stored in the cache
- **Entry** – The type of the items to be held in the cache.
- **Statistics** – A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the `CacheStatistics` concept. The default value is the type `statistics::no_statistics` which does not collect any numbers, but provides empty stubs allowing the code to compile.

## Public Types

```
using key_type = Key

using entry_type = Entry

using statistics_type = Statistics

using entry_pair = std::pair<key_type, entry_type>

using storage_type = std::list<entry_pair>

using map_type = std::map<Key, typename storage_type::iterator>

using size_type = std::size_t
```

## Public Functions

```
inline explicit lru_cache(size_type max_size = 0)
```

Construct an instance of a *lru\_cache*.

### Parameters

**max\_size** – [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry's *get\_size* function.

```
lru_cache(lru_cache const &other) = default
```

```
lru_cache(lru_cache &&other) = default
```

```
lru_cache &operator=(lru_cache const &other) = default
```

```
lru_cache &operator=(lru_cache &&other) = default
```

```
~lru_cache() = default
```

```
inline constexpr size_type size() const noexcept
```

Return current size of the cache.

### Returns

The current size of this cache instance.

```
inline constexpr size_type capacity() const noexcept
```

Access the maximum size the cache is allowed to grow to.

---

**Note:** The unit of this value is usually determined by the unit of the return values of the entry's function *entry::get\_size*.

---

### Returns

The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

```
inline void reserve(size_type max_size)
```

Change the maximum size this cache can grow to.

**Parameters**

**max\_size** – [in] The new maximum size this cache will be allowed to grow to.

```
inline bool holds_key(key_type const &key) const
```

Check whether the cache currently holds an entry identified by the given key.

---

**Note:** This function does not call the entry’s function *entry::touch*. It just checks if the cache contains an entry corresponding to the given key.

---

**Parameters**

**key** – [in] The key for the entry which should be looked up in the cache.

**Returns**

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
inline bool get_entry(key_type const &key, key_type &realkey, entry_type &entry)
```

Get a specific entry identified by the given key.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

---

**Parameters**

- **key** – [in] The key for the entry which should be retrieved from the cache.
- **realkey[out]** – Return the full real key found in the cache
- **entry** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

**Returns**

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
inline bool get_entry(key_type const &key, entry_type const &entry)
```

Get a specific entry identified by the given key.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

---

**Parameters**

- **key** – [in] The key for the entry which should be retrieved from the cache.
- **entry** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

**Returns**

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

```
template<typename Entry_, typename =  
std::enable_if_t<std::is_convertible_v<std::decay_t<Entry_>, entry_type>>>  
inline bool insert(key_type const &key, Entry_ &&entry)
```

Insert a new entry into this cache.

---

**Note:** This function assumes that the entry is not in the cache already. Inserting an already existing entry is considered undefined behavior

---

#### Parameters

- **key** – [in] The key for the entry which should be added to the cache.
- **entry** – [in] The entry which should be added to the cache.

```
template<typename Entry_, typename =  
std::enable_if_t<std::is_convertible_v<std::decay_t<Entry_>, entry_type>>>  
inline void update(key_type const &key, Entry_ &&entry)
```

Update an existing element in this cache.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

---

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

---

#### Parameters

- **key** – [in] The key for the value which should be updated in the cache.
- **entry** – [in] The entry which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

```
template<typename F, typename Entry_,  
std::enable_if_t<std::is_convertible_v<std::decay_t<Entry_>, entry_type>, int> = 0>  
inline bool update_if(key_type const &key, Entry_ &&entry, F &&f)
```

Update an existing element in this cache.

---

**Note:** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

---

---

**Note:** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

---

#### Parameters

- **key** – [in] The key for the value which should be updated in the cache.
- **entry** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- **f** – [in] A callable taking two arguments, *k* and the key found in the cache (in that order). If *f* returns true, then the update will continue. If *f* returns false, then the update will not succeed.

#### Returns

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

```
template<typename Func>
inline size_type erase(Func const &ep)
```

Remove stored entries from the cache for which the supplied function object returns true.

#### Parameters

**ep** – [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is *true*.

#### Returns

This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get\_size* functions of the removed entries).

```
inline size_type erase()
```

Remove all stored entries from the cache.

#### Returns

This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get\_size* functions of the removed entries).

```
inline size_type clear()
```

Clear the cache.

Unconditionally removes all stored entries from the cache.

```
inline constexpr statistics_type const &get_statistics() const noexcept
```

Allow to access the embedded statistics instance.

#### Returns

This function returns a reference to the statistics instance embedded inside this cache

```
inline statistics_type &get_statistics() noexcept
```

## Private Types

enumerator **update\_entry**

enumerator **erase\_entry**

class **no\_statistics**

Subclassed by *hpx::util::cache::statistics::local\_statistics*

#### **Public Static Functions**

static inline constexpr void **got\_hit**() noexcept

The function *got\_hit* will be called by a cache instance whenever an entry got touched.

static inline constexpr void **got\_miss**() noexcept

The function *got\_miss* will be called by a cache instance whenever a requested entry has not been found in the cache.

static inline constexpr void **got\_insertion**() noexcept

The function *got\_insertion* will be called by a cache instance whenever a new entry has been inserted.

static inline constexpr void **got\_eviction**() noexcept

The function *got\_eviction* will be called by a cache instance whenever an entry has been removed from the cache because a new inserted entry let the cache grow beyond its capacity.

static inline constexpr void **clear**() noexcept

Reset all statistics.

static inline constexpr std::int64\_t **get\_get\_entry\_count**(bool) noexcept

The function *get\_get\_entry\_count* returns the number of invocations of the *get\_entry*() API function of the cache.

static inline constexpr std::int64\_t **get\_insert\_entry\_count**(bool) noexcept

The function *get\_insert\_entry\_count* returns the number of invocations of the *insert\_entry*() API function of the cache.

static inline constexpr std::int64\_t **get\_update\_entry\_count**(bool) noexcept

The function *get\_update\_entry\_count* returns the number of invocations of the *update\_entry*() API function of the cache.

static inline constexpr std::int64\_t **get\_erase\_entry\_count**(bool) noexcept

The function *get\_erase\_entry\_count* returns the number of invocations of the *erase*() API function of the cache.

static inline constexpr std::int64\_t **get\_get\_entry\_time**(bool) noexcept

The function *get\_get\_entry\_time* returns the overall time spent executing of the *get\_entry*() API function of the cache.

static inline constexpr std::int64\_t **get\_insert\_entry\_time**(bool) noexcept

The function *get\_insert\_entry\_time* returns the overall time spent executing of the *insert\_entry*() API function of the cache.

static inline constexpr std::int64\_t **get\_update\_entry\_time**(bool) noexcept

The function *get\_update\_entry\_time* returns the overall time spent executing of the *update\_entry*() API function of the cache.

static inline constexpr std::int64\_t **get\_erase\_entry\_time**(bool) noexcept

The function *get\_erase\_entry\_time* returns the overall time spent executing of the *erase*() API function of the cache.

struct **update\_on\_exit**

*#include <no\_statistics.hpp>* Helper class to update timings and counts on function exit.

### Public Functions

## hpx/cache/entries/size\_entry.hpp

Defined in header `hpx/cache/entries/size_entry.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace util
```

```
        namespace cache
```

```
            namespace entries
```

```
                template<typename Value>
```

```
class size_entry : public hpx::util::cache::entries::entry<Value>
```

*#include <hpx/cache/entries/size\_entry.hpp>* The `size_entry` type can be used to store values in a cache which have a size associated (such as files, etc.). Using this type as the cache's entry type makes sure that the entries with the biggest size are discarded from the cache first.

---

**Note:** The `size_entry` conforms to the `CacheEntry` concept.

---

---

**Note:** This type can be used to model a 'discard smallest first' cache policy if it is used with a `std::greater` as the caches' `UpdatePolicy` (instead of the default `std::less`).

---

#### Template Parameters

**Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and `less_than_comparable`.

#### Public Functions

**size\_entry**() = default

Any cache entry has to be default constructible.

```
inline explicit size_entry(Value const &val, std::size_t size = 0)
    noexcept(std::is_nothrow_constructible_v<base_type, Value
             const&>)
```

Construct a new instance of a cache entry holding the given value.

```
inline explicit size_entry(Value &&val, std::size_t size = 0) noexcept
```

Construct a new instance of a cache entry holding the given value.

```
inline constexpr std::size_t get_size() const noexcept
```

Return the 'size' of this entry.

#### Private Types

```
using base_type = entry<Value>
```

#### Private Members

```
std::size_t size_ = 0
```

## Friends

```
inline friend auto operator<(size_entry const &lhs, size_entry const &rhs) noexcept
    Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has a bigger size.
inline friend auto operator>(size_entry const &lhs, size_entry const &rhs) noexcept
inline friend auto operator<= (size_entry const &lhs, size_entry const &rhs) noexcept
inline friend auto operator>= (size_entry const &lhs, size_entry const &rhs) noexcept
inline friend auto operator== (size_entry const &lhs, size_entry const &rhs) noexcept
inline friend auto operator!= (size_entry const &lhs, size_entry const &rhs) noexcept
```

## hpx/cache/entries/lfu\_entry.hpp

Defined in header `hpx/cache/entries/lfu_entry.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

template<typename **Value**>

class **lfu\_entry** : public `hpx::util::cache::entries::entry<Value>`

*#include <hpx/cache/entries/lfu\_entry.hpp>* The `lfu_entry` type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least frequently used entries are discarded from the cache first.

---

**Note:** The `lfu_entry` conforms to the `CacheEntry` concept.

---

---

**Note:** This type can be used to model a ‘most frequently used’ cache policy if it is used with a `std::greater` as the caches’ `UpdatePolicy` (instead of the default `std::less`).

---

### Template Parameters

**Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and `less_than_comparable`.

## Public Functions

**lfu\_entry()** = default

Any cache entry has to be default constructible.

inline explicit **lfu\_entry**(*Value* const &val)  
noexcept(*std::is\_nothrow\_constructible\_v<base\_type, Value const&>*)

Construct a new instance of a cache entry holding the given value.

inline explicit **lfu\_entry**(*Value* &&val) noexcept

Construct a new instance of a cache entry holding the given value.

inline bool **touch**() noexcept

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LFU entry we store the reference count tracking the number of times this entry has been requested. This which will be used to compare the age of an entry during the invocation of the *operator<()*.

### Returns

This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

inline constexpr unsigned long const &**get\_access\_count**() const noexcept

## Private Types

using **base\_type** = *entry<Value>*

## Private Members

unsigned long **ref\_count\_** = 0

## Friends

inline friend auto **operator**<(*lfu\_entry* const &lhs, *lfu\_entry* const &rhs)

Compare the 'age' of two entries. An entry is 'older' than another entry if it has been accessed less frequently (LFU).

inline friend auto **operator**>(*lfu\_entry* const &lhs, *lfu\_entry* const &rhs)

inline friend auto **operator**<= (*lfu\_entry* const &lhs, *lfu\_entry* const &rhs)

inline friend auto **operator**>= (*lfu\_entry* const &lhs, *lfu\_entry* const &rhs)

inline friend auto **operator**== (*lfu\_entry* const &lhs, *lfu\_entry* const &rhs)

inline friend auto **operator**!= (*lfu\_entry* const &lhs, *lfu\_entry* const &rhs)

## hpx/cache/entries/entry.hpp

Defined in header hpx/cache/entries/entry.hpp.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

template<typename **Value**>

class **entry**

*#include <hpx/cache/entries/entry.hpp>*

### Template Parameters

**Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and less\_than\_comparable.

Subclassed by *hpx::util::cache::entries::fifo\_entry< Value >*,  
*hpx::util::cache::entries::lru\_entry< Value >*,  
*hpx::util::cache::entries::size\_entry< Value >*

### Public Types

using **value\_type** = *Value*

### Public Functions

**entry**() = default

Any cache entry has to be default constructible.

inline explicit **entry**(*value\_type* const &val)  
noexcept(*std::is\_nothrow\_copy\_constructible\_v<value\_type>*)

Construct a new instance of a cache entry holding the given value.

inline explicit **entry**(*value\_type* &&val) noexcept

Construct a new instance of a cache entry holding the given value.

inline *value\_type* &**get**() noexcept

Get a reference to the stored data value.

---

**Note:** This function is part of the CacheEntry concept

---

inline constexpr *value\_type* const &**get**() const noexcept

## Public Static Functions

static inline constexpr bool **touch**() noexcept

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

---

**Note:** It is possible to change the entry in a way influencing the sort criteria mandated by the UpdatePolicy. In this case the function should return *true* to indicate this to the cache, forcing to reorder the cache entries.

---

---

**Note:** This function is part of the CacheEntry concept

---

### Returns

This function should return *true* if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

static inline constexpr bool **insert**() noexcept

The function *insert* is called by a cache whenever it is about to be inserted into the cache.

---

**Note:** This function is part of the CacheEntry concept

---

### Returns

This function should return *true* if the entry should be added to the cache, otherwise it should return *false*.

static inline constexpr bool **remove**() noexcept

The function *remove* is called by a cache holding this instance whenever it is about to be removed from the cache.

---

**Note:** This function is part of the CacheEntry concept

---

### Returns

The return value can be used to avoid removing this instance from the cache. If the value is *true* it is ok to remove the entry, otherwise it will stay in the cache.

static inline constexpr std::size\_t **get\_size**() noexcept

Return the 'size' of this entry. By default, the size of each entry is just one (1), which is sensible if the cache has a limit (capacity) measured in number of entries.

## Private Members

*value\_type* **value\_**

## Friends

**friend auto operator (entry const &, entry const &)=default**

Forwarding operator<=> allowing to compare entries instead of the values.

## hpx/cache/entries/fifo\_entry.hpp

Defined in header `hpx/cache/entries/fifo_entry.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

template<typename **Value**>

class **fifo\_entry** : public `hpx::util::cache::entries::entry<Value>`

*#include <hpx/cache/entries/fifo\_entry.hpp>* The `fifo_entry` type can be used to store arbitrary values in a cache. Using this type as the cache's entry type makes sure that the least recently inserted entries are discarded from the cache first.

---

**Note:** The `fifo_entry` conforms to the `CacheEntry` concept.

---

---

**Note:** This type can be used to model a 'last in first out' cache policy if it is used with a `std::greater` as the caches' `UpdatePolicy` (instead of the default `std::less`).

---

## Template Parameters

**Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and `less_than_comparable`.

## Public Functions

**fifo\_entry()** = default

Any cache entry has to be default constructible.

```
inline explicit fifo_entry(Value const &val)
    noexcept(std::is_nothrow_constructible_v<base_type, Value
    const&>)
```

Construct a new instance of a cache entry holding the given value.

```
inline explicit fifo_entry(Value &&val) noexcept
```

Construct a new instance of a cache entry holding the given value.

```
inline constexpr bool insert()
```

The function *insert* is called by a cache whenever it is about to be inserted into the cache.

---

**Note:** This function is part of the CacheEntry concept

---

## Returns

This function should return *true* if the entry should be added to the cache, otherwise it should return *false*.

```
inline constexpr time_point const &get_creation_time() const noexcept
```

## Private Types

```
using base_type = entry<Value>
```

```
using time_point = std::chrono::steady_clock::time_point
```

## Private Members

```
time_point insertion_time_
```

## Friends

```
inline friend auto operator<(fifo_entry const &lhs, fifo_entry const &rhs)
```

Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has been created earlier (FIFO).

```
inline friend auto operator>(fifo_entry const &lhs, fifo_entry const &rhs)
```

```
inline friend auto operator<= (fifo_entry const &lhs, fifo_entry const &rhs)
```

```
inline friend auto operator>= (fifo_entry const &lhs, fifo_entry const &rhs)
```

```
inline friend auto operator== (fifo_entry const &lhs, fifo_entry const &rhs)
```

```
inline friend auto operator!= (fifo_entry const &lhs, fifo_entry const &rhs)
```

**hpx/cache/entries/lru\_entry.hpp**

Defined in header `hpx/cache/entries/lru_entry.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

template<typename **Value**>

class **lru\_entry** : public `hpx::util::cache::entries::entry<Value>`

*#include <hpx/cache/entries/lru\_entry.hpp>* The `lru_entry` type can be used to store arbitrary values in a cache. Using this type as the cache's entry type makes sure that the least recently used entries are discarded from the cache first.

---

**Note:** The `lru_entry` conforms to the `CacheEntry` concept.

---

---

**Note:** This type can be used to model a 'most recently used' cache policy if it is used with a `std::greater` as the caches' `UpdatePolicy` (instead of the default `std::less`).

---

### Template Parameters

**Value** – The data type to be stored in a cache. It has to be default constructible, copy constructible and `less_than_comparable`.

### Public Functions

inline **lru\_entry**()

Any cache entry has to be default constructible.

inline explicit **lru\_entry**(*Value* const &val)  
noexcept(`std::is_nothrow_constructible_v<base_type, Value const&>`)

Construct a new instance of a cache entry holding the given value.

inline explicit **lru\_entry**(*Value* &&val) noexcept

Construct a new instance of a cache entry holding the given value.

inline bool **touch**()

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LRU entry we store the time of the last access which will be used to compare the age of an entry during the invocation of the *operator<()*.

**Returns**

This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

```
inline constexpr time_point const &get_access_time() const noexcept
```

Returns the last access time of the entry.

**Private Types**

```
using base_type = entry<Value>
```

```
using time_point = std::chrono::steady_clock::time_point
```

**Private Members**

```
time_point access_time_
```

**Friends**

```
inline friend auto operator<(lru_entry const &lhs, lru_entry const &rhs)
```

Compare the 'age' of two entries. An entry is 'older' than another entry if it has been accessed less recently (LRU).

```
inline friend auto operator>(lru_entry const &lhs, lru_entry const &rhs)
```

```
inline friend auto operator<=(lru_entry const &lhs, lru_entry const &rhs)
```

```
inline friend auto operator>=(lru_entry const &lhs, lru_entry const &rhs)
```

```
inline friend auto operator==(lru_entry const &lhs, lru_entry const &rhs)
```

```
inline friend auto operator!=(lru_entry const &lhs, lru_entry const &rhs)
```

**checkpoint\_base**

See *Public API* for a list of names and headers that are part of the public HPX API.

**hpx/checkpoint\_base/checkpoint\_data.hpp**

Defined in header `hpx/checkpoint_base/checkpoint_data.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
    namespace util
```

## Functions

```
template<typename Container, typename ...Ts>
void save_checkpoint_data(Container &data, Ts&&... ts)
    save_checkpoint_data
```

`Save_checkpoint_data` takes any number of objects which a user may wish to store in the given container.

### Template Parameters

- **Container** – Container used to store the check-pointed data.
- **Ts** – Types of variables to checkpoint

### Parameters

- **data** – Container instance used to store the checkpoint data
- **ts** – Variable instances to be inserted into the checkpoint.

```
template<typename ...Ts>
std::size_t prepare_checkpoint_data(Ts const&... ts)
    prepare_checkpoint_data
```

`prepare_checkpoint_data` takes any number of objects which a user may wish to store in a subsequent `save_checkpoint_data` operation. The function will return the number of bytes necessary to store the data that will be produced.

### Template Parameters

**Ts** – Types of variables to checkpoint

### Parameters

**ts** – Variable instances to be inserted into the checkpoint.

```
template<typename Container, typename ...Ts>
void restore_checkpoint_data(Container const &cont, Ts&... ts)
    restore_checkpoint_data
```

`restore_checkpoint_data` takes any number of objects which a user may wish to restore from the given container. The sequence of objects has to correspond to the sequence of objects for the corresponding call to `save_checkpoint_data` that had used the given container instance.

### Template Parameters

- **Container** – Container used to restore the check-pointed data.
- **Ts** – Types of variables to restore

### Parameters

- **cont** – Container instance used to restore the checkpoint data
- **ts** – Variable instances to be restored from the container

```
struct checkpointing_tag

template<>

struct extra_data_helper<checkpointing_tag>
```

inline void assign(size_type count, T const &value)

template<typename InIter>
inline void assign(InIter first, InIter last)

inline void assign(std::initializer_list<T> ilist)

inline allocator_type get_allocator() const noexcept
    Returns the allocator associated with the container.

inline reference at(size_type pos)

inline const_reference at(size_type pos) const

```

inline *reference* **operator[]**(*size\_type* pos)

inline *const\_reference* **operator[]**(*size\_type* pos) const

inline *reference* **front**()

Returns a reference to the first element in the container. Calling front on an empty container is undefined.

inline *const\_reference* **front**() const

Returns a reference to the first element in the container. Calling front on an empty container is undefined.

inline *reference* **back**()

Returns a reference to the last element in the container. Calling back on an empty container is undefined.

inline *const\_reference* **back**() const

Returns a reference to the last element in the container. Calling back on an empty container is undefined.

inline *pointer* **data**() noexcept

Returns pointer to the underlying array serving as element storage. The pointer is such that range [*data()*; *data()* + *size()*) is always a valid range, even if the container is empty (*data()* is not dereference-able in that case).

inline *const\_pointer* **data**() const noexcept

Returns pointer to the underlying array serving as element storage. The pointer is such that range [*data()*; *data()* + *size()*) is always a valid range, even if the container is empty (*data()* is not dereference-able in that case).

inline *T* \***device\_data**() const noexcept

Returns a raw pointer corresponding to the address of the data allocated on the device.

inline *std::size\_t* **size**() const noexcept

inline *std::size\_t* **capacity**() const noexcept

inline bool **empty**() const noexcept

Returns: *size()* == 0.

inline void **resize**(*size\_type*)

Effects: If *size* <= *size()*, equivalent to calling *pop\_back()* *size()*

- *size* times. If *size()* < *size*, appends *size* - *size()* default-inserted elements to the sequence.

Requires: *T* shall be MoveInsertable and DefaultInsertable into \*this.

Remarks: If an exception is thrown other than by the move constructor of a non-CopyInsertable *T* there are no effects.

inline void **resize**(*size\_type*, *T* const&)

Effects: If *size* <= *size()*, equivalent to calling *pop\_back()* *size()* - *size* times. If *size()* < *size*, appends *size* - *size()* copies of *val* to the sequence.

Requires: *T* shall be CopyInsertable into \*this.

Remarks: If an exception is thrown there are no effects.

inline *iterator* **begin**() noexcept

inline *iterator* **end**() noexcept

inline *const\_iterator* **cbegin**() const noexcept

inline *const\_iterator* **cend**() const noexcept

inline *const\_iterator* **begin**() const noexcept

inline *const\_iterator* **end**() const noexcept

inline *reverse\_iterator* **rbegin**() noexcept

inline *reverse\_iterator* **rend**() noexcept

inline *const\_reverse\_iterator* **crbegin**() const noexcept

inline *const\_reverse\_iterator* **crend**() const noexcept

inline *const\_reverse\_iterator* **rbegin**() const noexcept

inline *const\_reverse\_iterator* **rend**() const noexcept

inline void **swap**(*vector* &other) noexcept

Effects: Exchanges the contents and capacity() of \*this with that of x.

Complexity: Constant time.

inline void **clear**() noexcept

Effects: Erases all elements in the range [begin(),end()). Destroys all elements in 'a'. Invalidates all references, pointers, and iterators referring to the elements of a and may invalidate the past-the-end iterator.

Post: a.empty() returns true.

Complexity: Linear.

## hpx/compute\_local/host/block\_fork\_join\_executor.hpp

Defined in header `hpx/compute_local/host/block_fork_join_executor.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

class **block\_fork\_join\_executor**

*#include <block\_fork\_join\_executor.hpp>* An executor with fork-join (blocking) semantics.

The *block\_fork\_join\_executor* creates on construction a set of worker threads that are kept alive for the duration of the executor. Copying the executor has reference semantics, i.e. copies of a *fork\_join\_executor* hold a reference to the worker threads of the original instance. Scheduling work through the executor concurrently from different threads is undefined behaviour.

The executor keeps a set of worker threads alive for the lifetime of the executor, meaning other work will not be executed while the executor is busy or waiting for work. The executor has a customizable delay after which it will yield to other work. Since starting and resuming the worker threads is a slow operation the executor should be reused whenever possible for multiple adjacent parallel algorithms or invocations of `bulk_(a)sync_execute`.

This behaviour is similar to the plain *fork\_join\_executor* except that the *block\_fork\_join\_executor* creates a hierarchy of *fork\_join\_executors*, one for each target used to initialize it.

### Public Functions

```
inline explicit block_fork_join_executor(threads::thread_priority const priority =
                                         threads::thread_priority::bound,
                                         threads::thread_stacksize const stacksize =
                                         threads::thread_stacksize::small_,
                                         fork_join_executor::loop_schedule const
                                         schedule =
                                         fork_join_executor::loop_schedule::static_,
                                         std::chrono::nanoseconds const yield_delay =
                                         std::chrono::milliseconds(1))
```

Construct a *block\_fork\_join\_executor*.

---

**Note:** This constructor will create one *fork\_join\_executor* for each numa domain

---

### Parameters

- **priority** – The priority of the worker threads.
- **stacksize** – The stacksize of the worker threads. Must not be `nostack`.
- **schedule** – The loop schedule of the parallel regions.
- **yield\_delay** – The time after which the executor yields to other work if it has not received any new work for execution.

```
inline explicit block_fork_join_executor(std::vector<compute::host::target> const
&targets, threads::thread_priority const priority
= threads::thread_priority::bound,
threads::thread_stacksize const stacksize =
threads::thread_stacksize::small_,
fork_join_executor::loop_schedule const
schedule =
fork_join_executor::loop_schedule::static_,
std::chrono::nanoseconds const yield_delay =
std::chrono::milliseconds(1))
```

Construct a *block\_fork\_join\_executor*.

---

**Note:** This constructor will create one *fork\_join\_executor* for each given target

---

#### Parameters

- **targets** – The list of targets to use for thread placement
- **priority** – The priority of the worker threads.
- **stacksize** – The stacksize of the worker threads. Must not be nostack.
- **schedule** – The loop schedule of the parallel regions.
- **yield\_delay** – The time after which the executor yields to other work if it has not received any new work for execution.

```

## hpx/coroutines/thread\_enums.hpp

Defined in header `hpx/coroutines/thread_enums.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

### Enums

enum class **thread\_schedule\_state** : `std::int8_t`

The *thread\_schedule\_state* enumerator encodes the current state of a *thread* instance

#### Task Lifecycle State Transitions:

```
stateDiagram-v2
    %% Creation Phase
    [*] --> Staged : task_staged
    [*] --> Pending : task_created
    [*] --> Suspended : task_created
    Staged --> Pending : task_created

    %% Execution Loop
    Pending --> Active : task_executing
    Active --> Pending : task_yielded

    %% Sleep / Wake Cycle
    Active --> Suspended : task_suspended
    Suspended --> Pending : task_resumed

    %% Termination Paths
    Active --> Terminated : task_completed
    Active --> Deleted : task_completed (Inline fast-path)
    Pending --> Terminated : task_completed (Aborted)
    Suspended --> Terminated : task_completed (Aborted)

    %% Cleanup (Destruction / Recycling)
    Terminated --> Deleted : task_deleted
    Deleted --> [*]
```

Values:

enumerator **unknown**

enumerator **active**

thread is currently active (running, has resources)

enumerator **pending**

thread is pending (ready to run, but no hardware resource available)

enumerator **suspended**

thread has been suspended (waiting for synchronization event, but still known and under control of the thread-manager)

enumerator **depleted**

thread has been depleted (deeply suspended, it is not known to the thread-manager)

enumerator **terminated**

thread has been stopped and may be garbage collected

enumerator **staged**

this is not a real thread state, but allows to reference staged task descriptions, which eventually will be converted into thread objects

enumerator **pending\_do\_not\_schedule**

this is not a real thread state, but allows to create a thread in pending state without scheduling it (internal, do not use)

enumerator **pending\_boost**

this is not a real thread state, but allows to suspend a thread in pending state without high priority rescheduling

enumerator **deleted**

thread has been stopped and was deleted

enum class **thread\_priority** : *std::int8\_t*

This enumeration lists all possible thread-priorities for HPX threads.

*Values:*

enumerator **unknown**

enumerator **default\_**

Will assign the priority of the task to the default (normal) priority.

enumerator **low**

Task goes onto a special low priority queue and will not be executed until all high/normal priority tasks are done, even if they are added after the low priority task.

enumerator **normal**

Task will be executed when it is taken from the normal priority queue, this is usually a first-in-first-out ordering of tasks (depending on scheduler choice). This is the default priority.

enumerator **high\_recursive**

The task is a high priority task and any child tasks spawned by this task will be made high priority as well - unless they are specifically flagged as non default priority.

enumerator **boost**

Same as *thread\_priority\_high* except that the thread will fall back to *thread\_priority\_normal* if resumed after being suspended.

enumerator **high**

Task goes onto a special high priority queue and will be executed before normal/low priority tasks are taken (some schedulers modify the behavior slightly and the documentation for those should be consulted).

enumerator **bound**

Task goes onto a special high priority queue and will never be stolen by another thread after initial assignment. This should be used for thread placement tasks such as OpenMP type for loops.

enumerator **initially\_bound**

Task initially goes onto a special high priority queue and will never be stolen by another thread after initial assignment. If the thread is rescheduled later, it will use normal priority.

enum class **thread\_restart\_state** : *std::int8\_t*

The *thread\_restart\_state* enumerator encodes the reason why a thread is being restarted

*Values:*

enumerator **unknown**enumerator **signaled**

The thread has been signaled.

enumerator **timeout**

The thread has been reactivated after a timeout.

enumerator **terminate**

The thread needs to be terminated.

enumerator **abort**

The thread needs to be aborted.

enum class **thread\_stacksize** : *std::int8\_t*

A *thread\_stacksize* references any of the possible stack-sizes for HPX threads.

*Values:*

enumerator **unknown**enumerator **small\_**

use small stack size (the underscore is to work around 'small' being defined to char on Windows)

enumerator **medium**

use medium sized stack size

enumerator **large**

use large stack size

enumerator **huge**

use very large stack size

enumerator **nostack**

this thread does not suspend (does not need a stack)

enumerator **current**

use size of current thread's stack

enumerator **default\_**

use default stack size

enumerator **minimal**

use minimally stack size

enumerator **maximal**

use maximally stack size

enum class **thread\_schedule\_hint\_mode** : *std::int8\_t*

The type of hint given when creating new tasks.

*Values:*

enumerator **none**

A hint that leaves the choice of scheduling entirely up to the scheduler.

enumerator **thread**

A hint that tells the scheduler to prefer scheduling a task on the local thread number associated with this hint. Local thread numbers are indexed from zero. It is up to the scheduler to decide how to interpret thread numbers that are larger than the number of threads available to the scheduler. Typically, thread numbers will wrap around when too large.

enumerator **numa**

A hint that tells the scheduler to prefer scheduling a task on the NUMA domain associated with this hint. NUMA domains are indexed from zero. It is up to the scheduler to decide how to interpret NUMA domain indices that are larger than the number of available NUMA domains to the scheduler. Typically, indices will wrap around when too large.

enum class **thread\_placement\_hint** : *std::int8\_t*

The type of hint given to the scheduler related to thread placement

The type of hint given to the scheduler related running a thread as a child directly in the context of the parent thread

*Values:*

enumerator **none**

No hint is specified. The implementation is free to chose what placement methods to use.

enumerator **depth\_first**

A hint that tells the scheduler to prefer spreading thread placement on a depth-first basis (i.e. consecutively scheduled threads are placed on the same core).

enumerator **breadth\_first**

A hint that tells the scheduler to prefer spreading thread placement on a breadth-first basis (i.e. consecutively scheduled threads are placed on the neighboring cores).

enumerator **depth\_first\_reverse**

A hint that tells the scheduler to prefer spreading thread placement on a depth-first basis (i.e. consecutively scheduled threads are placed on the same core). Threads are being scheduled in reverse order.

enumerator **breadth\_first\_reverse**

A hint that tells the scheduler to prefer spreading thread placement on a breadth-first basis (i.e. consecutively scheduled threads are placed on the neighboring cores). Threads are being scheduled in reverse order.

enum class **thread\_sharing\_hint** : *std::int8\_t*

The type of hint given to the scheduler related to whether it is ok to share the invoked function object between threads

*Values:*

enumerator **none**

No hint is specified. The implementation is free to chose what sharing methods to use.

enumerator **do\_not\_share\_function**

A hint that tells the scheduler to avoid sharing the given function (object) between threads.

enumerator **do\_not\_combine\_tasks**

A hint that tells the scheduler to avoid combining tasks on the same thread. This is important for tasks that may synchronize between each other, which could lead to deadlocks if those tasks are combined running by the same thread.

enum class **thread\_execution\_hint** : *std::int8\_t*

*Values:*

enumerator **none**

No hint is specified. Always run the thread in its own execution environment.

enumerator **run\_as\_child**

Attempt to run the thread in the execution context of the parent thread.

## Functions

*std::ostream &operator<<(std::ostream &os, thread\_schedule\_state t)*

char const \***get\_thread\_state\_name**(thread\_schedule\_state state) noexcept

Returns the name of the given state.

Get the readable string representing the name of the given thread\_state constant.

### Parameters

**state** – this represents the thread state.

*std::ostream &operator<<(std::ostream &os, thread\_priority t)*

char const \***get\_thread\_priority\_name**(thread\_priority priority) noexcept

Return the thread priority name.

Get the readable string representing the name of the given thread\_priority constant.

### Parameters

**priority** – this represents the thread priority.

*std::ostream &operator<<(std::ostream &os, thread\_restart\_state t)*

char const \***get\_thread\_state\_ex\_name**(thread\_restart\_state state) noexcept

Get the readable string representing the name of the given thread\_restart\_state constant.

char const \***get\_thread\_state\_name**(thread\_state state) noexcept

Get the readable string representing the name of the given thread\_state constant.

*std::ostream &operator<<(std::ostream &os, thread\_stacksize t)*

char const \***get\_stack\_size\_enum\_name**(thread\_stacksize size) noexcept

Returns the stack size name.

Get the readable string representing the given stack size constant.

### Parameters

**size** – this represents the stack size

constexpr bool **do\_not\_share\_function**(thread\_sharing\_hint hint) noexcept

constexpr bool **do\_not\_combine\_tasks**(thread\_sharing\_hint hint) noexcept

constexpr thread\_sharing\_hint **operator|**(thread\_sharing\_hint lhs, thread\_sharing\_hint rhs) noexcept

constexpr bool **run\_as\_child**(thread\_execution\_hint hint) noexcept

## Variables

constexpr *thread\_execution\_hint* **default\_runs\_as\_child\_hint** = *thread\_execution\_hint::none*

Default value to use for runs-as-child mode (if *true*, then futures will attempt to execute associated threads directly if they have not started running).

struct **thread\_schedule\_hint**

*#include <thread\_enums.hpp>* A hint given to a scheduler to guide where a task should be scheduled.

A scheduler is free to ignore the hint, or modify the hint to suit the resources available to the scheduler.

## Public Functions

inline constexpr **thread\_schedule\_hint**() noexcept

Construct a default hint with mode *thread\_schedule\_hint\_mode::none*.

inline explicit constexpr **thread\_schedule\_hint**(*std::int16\_t* const *thread\_hint*,  
*thread\_placement\_hint* placement =  
*thread\_placement\_hint::none*,  
*thread\_execution\_hint* runs\_as\_child =  
*default\_runs\_as\_child\_hint*,  
*thread\_sharing\_hint* sharing =  
*thread\_sharing\_hint::none*) noexcept

Construct a hint with mode *thread\_schedule\_hint\_mode::thread* and the given hint as the local thread number.

inline constexpr **thread\_schedule\_hint**(*thread\_schedule\_hint\_mode* const mode, *std::int16\_t*  
const *hint*, *thread\_placement\_hint* placement =  
*thread\_placement\_hint::none*, *thread\_execution\_hint*  
runs\_as\_child = *default\_runs\_as\_child\_hint*,  
*thread\_sharing\_hint* sharing =  
*thread\_sharing\_hint::none*) noexcept

Construct a hint with the given mode and hint. The numerical hint is unused when the mode is *thread\_schedule\_hint\_mode::none*.

inline explicit constexpr **thread\_schedule\_hint**(*thread\_placement\_hint* placement) noexcept

Construct a hint with the given placement hint.

inline explicit constexpr **thread\_schedule\_hint**(*thread\_execution\_hint* runs\_as\_child) noexcept

Construct a hint with the given execution hint.

inline explicit constexpr **thread\_schedule\_hint**(*thread\_sharing\_hint* sharing) noexcept

Construct a hint with the given sharing hint.

inline constexpr *thread\_placement\_hint* **placement\_mode**() const noexcept

inline constexpr void **placement\_mode**(*thread\_placement\_hint* bits) noexcept

inline constexpr *thread\_sharing\_hint* **sharing\_mode**() const noexcept

inline constexpr void **sharing\_mode**(*thread\_sharing\_hint* bits) noexcept

inline constexpr *thread\_execution\_hint* **runs\_as\_child\_mode**() const noexcept

```
inline constexpr void runs_as_child_mode(thread_execution_hint bits) noexcept
```

```
inline constexpr void schedule_hint(std::int16_t core) noexcept
```

### Public Members

```
std::int16_t hint = -1
```

The hint associated with the mode. The interpretation of this hint depends on the given mode.

```
thread_schedule_hint_mode mode = thread_schedule_hint_mode::none
```

The mode of the scheduling hint.

```
std::uint8_t placement_mode_bits
```

The mode of the desired thread placement.

```
std::uint8_t sharing_mode_bits
```

The mode of the desired sharing hint.

```
std::uint8_t runs_as_child_mode_bits
```

The thread will run as a child directly in the context of the current thread

### datastructures

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
hpx::any_nonser.           hpx::bad_any_cast,    hpx::unique_any_nonser,    hpx::any_cast,  
hpx::make_any_nonser, hpx::make_unique_any_nonser
```

Defined in header [hpx/any.hpp](#)<sup>718</sup>.

template<typename **T**, typename **IArch**, typename **OArch**, typename **Char**, typename **Copyable**>  
**T** \***any\_cast**(*util::basic\_any*<**IArch**, **OArch**, **Char**, **Copyable**> \*operand) noexcept

Performs type-safe access to the contained object.

### Parameters

**operand** – target any object

**Returns**

If operand is not a null pointer, and the *typeid* of the requested *T* matches that of the contents of *operand*, a pointer to the value contained by *operand*, otherwise a null pointer.

```
template<typename T, typename IArch, typename OArch, typename Char, typename Copyable>
T const *any_cast(util::basic_any<IArch, OArch, Char, Copyable> const *operand) noexcept
```

Performs type-safe access to the contained object.

**Parameters**

**operand** – target any object

**Returns**

If operand is not a null pointer, and the *typeid* of the requested *T* matches that of the contents of *operand*, a pointer to the value contained by *operand*, otherwise a null pointer.

```
template<typename T, typename IArch, typename OArch, typename Char, typename Copyable>
T any_cast(util::basic_any<IArch, OArch, Char, Copyable> &operand)
```

Performs type-safe access to the contained object. Let *U* be `std::remove_cv_t<std::remove_reference_t<T>>`. The program is ill-formed if `std::is_constructible_v<T, U&>` is false.

**Parameters**

**operand** – target any object

**Returns**

`static_cast<T>(*std::any_cast<U>(&operand))`

```
template<typename T, typename IArch, typename OArch, typename Char, typename Copyable>
T const &any_cast(util::basic_any<IArch, OArch, Char, Copyable> const &operand)
```

Performs type-safe access to the contained object. Let *U* be `std::remove_cv_t<std::remove_reference_t<T>>`. The program is ill-formed if `std::is_constructible_v<T, const U&>` is false.

**Parameters**

**operand** – target any object

**Returns**

`static_cast<T>(*std::any_cast<U>(&operand))`

```
struct bad_any_cast : public bad_cast
```

`#include <any.hpp>` Defines a type of object to be thrown by the value-returning forms of `hpx::any_cast` on failure.

**Public Functions**

```
inline bad_any_cast(std::type_info const &src, std::type_info const &dest)
```

Constructs a new *bad\_any\_cast* object with an implementation-defined null-terminated byte string which is accessible through *what()*.

```
inline char const *what() const noexcept override
```

Returns the explanatory string.

---

**Note:** Implementations are allowed but not required to override *what()*.

---

**Returns**

Pointer to a null-terminated string with explanatory information. The string is suitable for conversion and display as a `std::wstring`. The pointer is guaranteed to be valid at least until the exception object from which it is obtained is destroyed, or until a non-const member function (e.g. copy assignment operator) on the exception object is called.

**Public Members**

`char const *from`

`char const *to`

**hpx::ignore**, **hpx::tuple**, **hpx::tuple\_size**, **hpx::tuple\_element**, **hpx::make\_tuple**, **hpx::tie**,  
**hpx::forward\_as\_tuple**, **hpx::tuple\_cat**, **hpx::get**

Defined in header [hpx/tuple.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/tuple.hpp)<sup>719</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

### Functions

```
template<typename ...Ts>
constexpr tuple<util::decay_unwrap_t<Ts>...> make_tuple(Ts&&... ts)
```

Provides compile-time indexed access to the types of the elements of the tuple.

```
template<typename ...Ts>
```

---

<sup>719</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/tuple.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/tuple.hpp)

constexpr *tuple*<Ts&&...> **forward\_as\_tuple**(Ts&&... ts)

Constructs a tuple of references to the arguments in args suitable for forwarding as an argument to a function. The tuple has rvalue reference data members when rvalues are used as arguments, and otherwise has lvalue reference data members.

#### Parameters

**ts** – zero or more arguments to construct the tuple from

#### Returns

*hpx::tuple* object created as if by

```
hpx::tuple<Ts&&...>(HPX_FORWARD(Ts, ts) ...)
```

template<typename ...Ts>

constexpr *tuple*<Ts&...> **tie**(Ts&... ts)

Creates a tuple of lvalue references to its arguments or instances of *hpx::ignore*.

#### Parameters

**ts** – zero or more lvalue arguments to construct the tuple from.

#### Returns

*hpx::tuple* object containing lvalue references.

template<typename ...Tuples>

constexpr auto **tuple\_cat**(Tuples&&... tuples)

Constructs a tuple that is a concatenation of all tuples in **tuples**. The behavior is undefined if any type in `std::decay_t<Tuples>...` is not a specialization of *hpx::tuple*. However, an implementation may choose to support types (such as `std::array` and `std::pair`) that follow the tuple-like protocol.

#### Parameters

**tuples** – - zero or more tuples to concatenate

#### Returns

*hpx::tuple* object composed of all elements of all argument tuples constructed from *hpx::get*<Is>(HPX\_FORWARD(UTuple,t) for each individual element.

template<std::size\_t I>

*util::at\_index*<I, Ts...>::type &**get**() noexcept

Extracts the Ith element from the tuple. I must be an integer value in [0, sizeof...(Ts)).

template<std::size\_t I>

*util::at\_index*<I, Ts...>::type const &**get**() const noexcept

Extracts the Ith element from the tuple. I must be an integer value in [0, sizeof...(Ts)).

## Variables

constexpr *hpx::detail::ignore\_type* **ignore** = {}

An object of unspecified type such that any value can be assigned to it with no effect. Intended for use with *hpx::tie* when unpacking a *hpx::tuple*, as a placeholder for the arguments that are not used. While the behavior of *hpx::ignore* outside of *hpx::tie* is not formally specified, some code guides recommend using *hpx::ignore* to avoid warnings from unused return values of `[[nodiscard]]` functions.

template<typename ...Ts>

class **tuple**

*#include <tuple.hpp>* Class template *hpx::tuple* is a fixed-size collection of heterogeneous values. It is

a generalization of `hpx::pair`. If `std::is_trivially_destructible<Ti>::value` is true for every `Ti` in `Ts`, the destructor of tuple is trivial.

**Param Ts...**

the types of the elements that the tuple stores.

```
template<std::size_t I, typename T, typename Enable = void>
```

```
struct tuple_element
```

*#include <tuple.hpp>* Provides compile-time indexed access to the types of the elements of a tuple-like type.

The primary template is not defined. An explicit (full) or partial specialization is required to make a type tuple-like.

```
template<typename T>
```

```
struct tuple_size
```

*#include <tuple.hpp>* Provides access to the number of elements in a tuple-like type as a compile-time constant expression.

The primary template is not defined. An explicit (full) or partial specialization is required to make a type tuple-like.

## hpx::any, hpx::make\_any

Defined in header `hpx/any.hpp`<sup>720</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
template<typename IArch, typename OArch, typename Char>
```

namespace **hpx**

### `hpx/errors/macros.hpp`

Defined in header `hpx/errors/macros.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

---

<sup>721</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/exception.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/exception.hpp)

## Defines

### HPX\_THROW\_EXCEPTION(errcode, f, ...)

Throw a *hpx::exception* initialized from the given parameters.

The macro *HPX\_THROW\_EXCEPTION* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter *errcode* holds the *hpx::error* code the new exception should encapsulate. The parameter *f* is expected to hold the name of the function exception is thrown from and the parameter *msg* holds the error message the new exception should encapsulate.

```
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_EXCEPTION(hpx::error::no_success, "raise_exception",
        "simulated error");
}
```

#### Example:

### HPX\_THROW\_BAD\_ALLOC(f)

Throw a *hpx::bad\_alloc\_exception* initialized from the given parameters.

The macro *HPX\_THROW\_BAD\_ALLOC* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter *errcode* holds the *hpx::error* code the new exception should encapsulate. The parameter *f* is expected to hold the name of the function exception is thrown from and the parameter *msg* holds the error message the new exception should encapsulate.

```
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_BAD_ALLOC("raise_exception", "simulated error");
}
```

#### Example:

### HPX\_THROWS\_IF(ec, errcode, f, ...)

Either throw a *hpx::exception* or initialize *hpx::error\_code* from the given parameters.

The macro *HPX\_THROWS\_IF* can be used to either throw a `hpx::exception` or to initialize a `hpx::error_code` from the given parameters. If `&ec == &hpx::throws`, the semantics of this macro are equivalent to *HPX\_THROW\_EXCEPTION*. If `&ec != &hpx::throws`, the `hpx::error_code` instance `ec` is initialized instead.

The parameter `errcode` holds the `hpx::error_code` from which the new exception should be initialized. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

#### **HPX\_THROWS\_BAD\_ALLOC\_IF**(`ec, f`)

Either throw a *hpx::bad\_alloc\_exception* or `hpx::error_code` to *out\_of\_memory*.

The macro *HPX\_THROWS\_BAD\_ALLOC\_IF* can be used to either throw a `hpx::bad_alloc_exception` or to initialize a `hpx::error_code` to *hpx::error::out\_of\_memory*. If `&ec == &hpx::throws`, the semantics of this macro are equivalent to *HPX\_THROW\_BAD\_ALLOC*. If `&ec != &hpx::throws`, the `hpx::error_code` instance `ec` is initialized instead.

#### **HPX\_DEFINE\_ERROR\_INFO**(`NAME, TYPE`)

### **hpx/errors/error.hpp**

Defined in header `hpx/errors/error.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### **Defines**

#### **HPX\_ERROR\_UNSCOPED\_ENUM\_DEPRECATION\_MSG**

namespace **hpx**

### **Enums**

enum class **error** : *std::int16\_t*

Possible error conditions.

This enumeration lists all possible error conditions which can be reported from any of the API functions.

*Values:*

enumerator **success**

The operation was successful.

enumerator **no\_success**

The operation did failed, but not in an unexpected manner.

enumerator **not\_implemented**

The operation is not implemented.

enumerator **out\_of\_memory**

The operation caused an out of memory condition.

enumerator **bad\_action\_code**

enumerator **bad\_component\_type**

The specified component type is not known or otherwise invalid.

enumerator **network\_error**

A generic network error occurred.

enumerator **version\_too\_new**

The version of the network representation for this object is too new.

enumerator **version\_too\_old**

The version of the network representation for this object is too old.

enumerator **version\_unknown**

The version of the network representation for this object is unknown.

enumerator **unknown\_component\_address**

enumerator **duplicate\_component\_address**

The given global id has already been registered.

enumerator **invalid\_status**

The operation was executed in an invalid status.

enumerator **bad\_parameter**

One of the supplied parameters is invalid.

enumerator **internal\_server\_error**

enumerator **service\_unavailable**

enumerator **bad\_request**

enumerator **repeated\_request**

enumerator **lock\_error**

enumerator **duplicate\_console**

There is more than one console locality.

enumerator **no\_registered\_console**

There is no registered console locality available.

enumerator **startup\_timed\_out**

enumerator **uninitialized\_value**

enumerator **bad\_response\_type**

enumerator **deadlock**

enumerator **assertion\_failure**

enumerator **null\_thread\_id**

Attempt to invoke an API function from a non-HPX thread.

enumerator **invalid\_data**

enumerator **yield\_aborted**

The yield operation was aborted.

enumerator **dynamic\_link\_failure**

enumerator **commandline\_option\_error**

One of the options given on the command line is erroneous.

enumerator **serialization\_error**

There was an error during serialization of this object.

enumerator **unhandled\_exception**

An unhandled exception has been caught.

enumerator **kernel\_error**

The OS kernel reported an error.

enumerator **broken\_task**

The task associated with this future object is not available anymore.

enumerator **task\_moved**

The task associated with this future object has been moved.

enumerator **task\_already\_started**

The task associated with this future object has already been started.

enumerator **future\_already\_retrieved**

The future object has already been retrieved.

enumerator **promise\_already\_satisfied**

The value for this future object has already been set.

enumerator **future\_does\_not\_support\_cancellation**

The future object does not support cancellation.

enumerator **future\_can\_not\_be\_cancelled**

The future can't be canceled at this time.

enumerator **no\_state**

The future object has no valid shared state.

enumerator **broken\_promise**

The promise has been deleted.

enumerator **thread\_resource\_error**

enumerator **future\_cancelled**

enumerator **thread\_cancelled**

enumerator **thread\_not\_interruptable**

enumerator **duplicate\_component\_id**

The component type has already been registered.

enumerator **unknown\_error**

An unknown error occurred.

enumerator **bad\_plugin\_type**

The specified plugin type is not known or otherwise invalid.

enumerator **filesystem\_error**

The specified file does not exist or other filesystem related error.

enumerator **bad\_function\_call**

equivalent of `std::bad_function_call`

enumerator **task\_canceled\_exception**

`parallel::task_canceled_exception`

enumerator **task\_block\_not\_active**

`task_region` is not active

enumerator **out\_of\_range**

Equivalent to `std::out_of_range`.

enumerator **length\_error**

Equivalent to `std::length_error`.

enumerator **migration\_needs\_retry**

migration failed because of global race, retry

### hpx/errors/exception\_fwd.hpp

Defined in header `hpx/errors/exception_fwd.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Enums

```
enum class throwmode : std::uint8_t
    Encode error category for new error_code.
    Values:

    enumerator plain

    enumerator rethrow

    enumerator lightweight
```

## Functions

constexpr bool **operator&**(*throwmode* lhs, *throwmode* rhs) noexcept

## Variables

*error\_code* **throws**

Predefined *error\_code* object used as “throw on error” tag.

The predefined *hpx::error\_code* object *hpx::throws* is supplied for use as a “throw on error” tag.

Functions that specify an argument in the form ‘*error\_code*& ec=throws’ (with appropriate namespace qualifiers), have the following error handling semantics:

If &ec != &throws and an error occurred: ec.value() returns the implementation specific error number for the particular error that occurred and ec.category() returns the error\_category for ec.value().

If &ec != &throws and an error did not occur, ec.clear().

If an error occurs and &ec == &throws, the function throws an exception of type *hpx::exception* or of a type derived from it. The exception’s *get\_errorcode()* member function returns a reference to a *hpx::error\_code* object with the behavior as specified above.

## hpx/errors/exception\_list.hpp

Defined in header *hpx/errors/exception\_list.hpp*.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

class **exception\_list** : public *hpx::exception*

*#include <exception\_list.hpp>* The class *exception\_list* is a container of *exception\_ptr* objects parallel algorithms may use to communicate uncaught exceptions encountered during parallel execution to the caller of the algorithm

The type *exception\_list::const\_iterator* fulfills the requirements of a forward iterator.

## Public Types

using **iterator** = *exception\_list\_type::const\_iterator*  
bidirectional iterator

## Public Functions

inline `std::size_t size()` const noexcept

The number of `exception_ptr` objects contained within the `exception_list`.

---

**Note:** Complexity: Constant time.

---

inline `exception_list_type::const_iterator begin()` const noexcept

An iterator referring to the first `exception_ptr` object contained within the `exception_list`.

inline `exception_list_type::const_iterator end()` const noexcept

An iterator which is the past-the-end value for the `exception_list`.

## hpx::exception

Defined in header `hpx/exception.hpp`<sup>722</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Typedefs

using **custom\_exception\_info\_handler\_type** = `std::function<hpx::exception_info(std::string const&, std::string const&, long, std::string const&)>`

using **pre\_exception\_handler\_type** = `std::function<void()>`

## Functions

void **set\_custom\_exception\_info\_handler**(`custom_exception_info_handler_type f`)

void **set\_pre\_exception\_handler**(`pre_exception_handler_type f`)

`std::string` **get\_error\_what**(`exception_info const &xi`)

Return the error message of the thrown exception.

The function `hpx::get_error_what` can be used to extract the diagnostic information element representing the error message as stored in the given exception instance.

### See also:

<sup>722</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/exception.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/exception.hpp)

**Parameters**

**xi** – The parameter *e* will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception\_info*, *hpx::error\_code*, *std::exception*, or *std::exception\_ptr*.

**Throws**

*std::bad\_alloc* – (if one of the required allocations fails)

**Returns**

The error message stored in the exception. If the exception instance does not hold this information, the function will return an empty string.

*error* **get\_error**(*hpx::exception* const &*e*)

Return the error code value of the exception thrown.

The function *hpx::get\_error* can be used to extract the diagnostic information element representing the error value code as stored in the given exception instance.

**See also:**

*hpx::diagnostic\_information*(), *hpx::get\_error\_host\_name*(), *hpx::get\_error\_process\_id*(),  
*hpx::get\_error\_function\_name*(), *hpx::get\_error\_file\_name*(), *hpx::get\_error\_line\_number*(),  
*hpx::get\_error\_os\_thread*(), *hpx::get\_error\_thread\_id*(), *hpx::get\_error\_thread\_description*(),  
*hpx::get\_error\_backtrace*(), *hpx::get\_error\_env*(), *hpx::get\_error\_what*(), *hpx::get\_error\_config*(),  
*hpx::get\_error\_state*()

**Parameters**

**e** – The parameter *e* will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception*, *hpx::error\_code*, or *std::exception\_ptr*.

**Throws**

nothing –

**Returns**

The error value code of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return *hpx::naming::invalid\_locality\_id*.

*error* **get\_error**(*hpx::error\_code* const &*e*)

*std::string* **get\_error\_function\_name**(*hpx::exception\_info* const &*xi*)

Return the function name from which the exception was thrown.

The function *hpx::get\_error\_function\_name* can be used to extract the diagnostic information element representing the name of the function as stored in the given exception instance.

**See also:**

*hpx::diagnostic\_information*(), *hpx::get\_error\_host\_name*(), *hpx::get\_error\_process\_id*(),  
*hpx::get\_error\_file\_name*(), *hpx::get\_error\_line\_number*(), *hpx::get\_error\_os\_thread*(),  
*hpx::get\_error\_thread\_id*(), *hpx::get\_error\_thread\_description*(), *hpx::get\_error*(),  
*hpx::get\_error\_backtrace*(), *hpx::get\_error\_env*(), *hpx::get\_error\_what*(), *hpx::get\_error\_config*(),  
*hpx::get\_error\_state*()

**Parameters**

**xi** – The parameter *e* will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception\_info*, *hpx::error\_code*, *std::exception*, or *std::exception\_ptr*.

**Throws**

*std::bad\_alloc* – (if one of the required allocations fails)

**Returns**

The name of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

*std::string* **get\_error\_file\_name**(*hpx::exception\_info* const &xi)

Return the (source code) file name of the function from which the exception was thrown.

The function *hpx::get\_error\_file\_name* can be used to extract the diagnostic information element representing the name of the source file as stored in the given exception instance.

**See also:**

*hpx::diagnostic\_information()*, *hpx::get\_error\_host\_name()*, *hpx::get\_error\_process\_id()*,  
*hpx::get\_error\_function\_name()*, *hpx::get\_error\_line\_number()*, *hpx::get\_error\_os\_thread()*,  
*hpx::get\_error\_thread\_id()*, *hpx::get\_error\_thread\_description()*, *hpx::get\_error()*,  
*hpx::get\_error\_backtrace()*, *hpx::get\_error\_env()*, *hpx::get\_error\_what()*, *hpx::get\_error\_config()*,  
*hpx::get\_error\_state()*

**Parameters**

**xi** – The parameter *e* will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception\_info*, *hpx::error\_code*, *std::exception*, or *std::exception\_ptr*.

**Throws**

*std::bad\_alloc* – (if one of the required allocations fails)

**Returns**

The name of the source file of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

long **get\_error\_line\_number**(*hpx::exception\_info* const &xi)

Return the line number in the (source code) file of the function from which the exception was thrown.

The function *hpx::get\_error\_line\_number* can be used to extract the diagnostic information element representing the line number as stored in the given exception instance.

**See also:**

*hpx::diagnostic\_information()*, *hpx::get\_error\_host\_name()*, *hpx::get\_error\_process\_id()*,  
*hpx::get\_error\_function\_name()*, *hpx::get\_error\_file\_name()*, *hpx::get\_error\_os\_thread()*,  
*hpx::get\_error\_thread\_id()*, *hpx::get\_error\_thread\_description()*, *hpx::get\_error()*,  
*hpx::get\_error\_backtrace()*, *hpx::get\_error\_env()*, *hpx::get\_error\_what()*, *hpx::get\_error\_config()*,  
*hpx::get\_error\_state()*

**Parameters**

**xi** – The parameter *e* will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception\_info*, *hpx::error\_code*, *std::exception*, or *std::exception\_ptr*.

**Throws**

nothing –

**Returns**

The line number of the place where the exception was thrown. If the exception instance does not hold this information, the function will return -1.

```
class bad_alloc_exception : public hpx::exception, public bad_alloc
```

**Public Functions****bad\_alloc\_exception()**

Construct a *hpx::bad\_alloc\_exception*.

*error\_code* **get\_error\_code**(*throwmode mode = throwmode::plain*) const noexcept

The function *get\_error\_code()* returns a *hpx::error\_code* which represents the same error condition as this *hpx::exception* instance.

**Parameters**

**mode** – The parameter *mode* specifies whether the returned *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *throwmode::plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

**Public Static Functions**

```
static inline constexpr error get_error() noexcept
```

The function *get\_error()* returns *hpx::error::out\_of\_memory*

**Throws**

nothing –

```
class exception : public system_error
```

*#include <exception.hpp>* A *hpx::exception* is the main exception type used by HPX to report errors.

The *hpx::exception* type is the main exception type used by HPX to report errors. Any exceptions thrown by functions in the HPX library are either of this type or of a type derived from it. This implies that it is always safe to use this type only in catch statements guarding HPX library calls.

Subclassed by *hpx::bad\_alloc\_exception*, *hpx::exception\_list*

## Public Functions

explicit **exception**(*error e = hpx::error::success*)

Construct a *hpx::exception* from a *hpx::error*.

### Parameters

**e** – The parameter *e* holds the *hpx::error* code the new exception should encapsulate.

explicit **exception**(*std::system\_error const &e*)

Construct a *hpx::exception* from a *boost::system\_error*.

explicit **exception**(*std::error\_code const &e*)

Construct a *hpx::exception* from a *boost::system::error\_code* (this is new for Boost V1.69). This constructor is required to compensate for the changes introduced as a resolution to LWG3162 (<https://cplusplus.github.io/LWG/issue3162>).

**exception**(*error e, char const \*msg, throwmode mode = throwmode::plain*)

Construct a *hpx::exception* from a *hpx::error* and an error message.

### Parameters

- e** – The parameter *e* holds the *hpx::error* code the new exception should encapsulate.
- msg** – The parameter *msg* holds the error message the new exception should encapsulate.
- mode** – The parameter *mode* specifies whether the returned *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

**exception**(*error e, std::string const &msg, throwmode mode = throwmode::plain*)

Construct a *hpx::exception* from a *hpx::error* and an error message.

### Parameters

- e** – The parameter *e* holds the *hpx::error* code the new exception should encapsulate.
- msg** – The parameter *msg* holds the error message the new exception should encapsulate.
- mode** – The parameter *mode* specifies whether the returned *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

**~exception**() override

Destruct a *hpx::exception*

### Throws

nothing –

*error* **get\_error**() const noexcept

The function *get\_error()* returns the *hpx::error* code stored in the referenced instance of a *hpx::exception*. It returns the *hpx::error* code this exception instance was constructed from.

### Throws

nothing –

*error\_code* **get\_error\_code**(*throwmode mode = throwmode::plain*) const noexcept

The function *get\_error\_code()* returns a *hpx::error\_code* which represents the same error condition as this *hpx::exception* instance.

### Parameters

- mode** – The parameter *mode* specifies whether the returned *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *throwmode::plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

struct **thread\_interrupted** : public *exception*

*#include <exception.hpp>* A *hpx::thread\_interrupted* is the exception type used by HPX to interrupt a running HPX thread.

The `hpx::thread_interrupted` type is the exception type used by HPX to interrupt a running thread.

A running thread can be interrupted by invoking the `interrupt()` member function of the corresponding `hpx::thread` object. When the interrupted thread next executes one of the specified interruption points (or if it is currently blocked whilst executing one) with interruption enabled, then a *`hpx::thread_interrupted`* exception will be thrown in the interrupted thread. If not caught, this will cause the execution of the interrupted thread to terminate. As with any other exception, the stack will be unwound, and destructors for objects of automatic storage duration will be executed.

If a thread wishes to avoid being interrupted, it can create an instance of *`hpx::this_thread::disable_interruption`*. Objects of this class disable interruption for the thread that created them on construction, and restore the interruption state to whatever it was before on destruction.

```
void f()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::disable_interruption di2;
            // interruption still disabled
        } // di2 destroyed, interruption state restored
        // interruption still disabled
    } // di destroyed, interruption state restored
    // interruption now enabled
}
```

The effects of an instance of *`hpx::this_thread::disable_interruption`* can be temporarily reversed by constructing an instance of *`hpx::this_thread::restore_interruption`*, passing in the *`hpx::this_thread::disable_interruption`* object in question. This will restore the interruption state to what it was when the *`hpx::this_thread::disable_interruption`* object was constructed, and then disable interruption again when the *`hpx::this_thread::restore_interruption`* object is destroyed.

```
void g()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::restore_interruption ri(di);
            // interruption now enabled
        } // ri destroyed, interruption disable again
    } // di destroyed, interruption state restored
    // interruption now enabled
}
```

At any point, the interruption state for the current thread can be queried by calling *`hpx::this_thread::interruption_enabled()`*.

## hpx/errors/define\_error\_info.hpp

Defined in header `hpx/errors/define_error_info.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## hpx::error\_code

Defined in header `hpx/system_error.hpp`<sup>723</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Unnamed Group

```
inline error_code make_error_code(std::exception_ptr const &e)
```

```
inline error_code make_error_code(error e, throwmode mode = throwmode::plain)
```

Returns a new *error\_code* constructed from the given parameters.

```
inline error_code make_error_code(error e, char const *func, char const *file, long line, throwmode mode = throwmode::plain)
```

```
inline error_code make_error_code(error e, char const *msg, throwmode mode = throwmode::plain)
```

Returns *error\_code*(e, msg, mode).

```
inline error_code make_error_code(error e, char const *msg, char const *func, char const *file, long line, throwmode mode = throwmode::plain)
```

```
inline error_code make_error_code(error e, std::string const &msg, throwmode mode = throwmode::plain)
```

Returns *error\_code*(e, msg, mode).

```
inline error_code make_error_code(error e, std::string const &msg, char const *func, char const *file, long line, throwmode mode = throwmode::plain)
```

### Functions

```
std::error_category const &get_hpx_category() noexcept
```

Returns generic HPX error category used for new errors.

```
std::error_category const &get_hpx_rethrow_category() noexcept
```

Returns generic HPX error category used for errors re-thrown after the exception has been de-serialized.

```
inline error_code make_success_code(throwmode mode = throwmode::plain)
```

Returns *error\_code*(hpx::error::success, “success”, mode).

<sup>723</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/system\\_error.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/system_error.hpp)

class **error\_code** : public *error\_code*

*#include <error\_code.hpp>* A *hpx::error\_code* represents an arbitrary error condition.

The class *hpx::error\_code* describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

---

**Note:** Class *hpx::error\_code* is an adjunct to error reporting by exception

---

## Public Functions

inline explicit **error\_code**(*throwmode* mode = *throwmode::plain*)

Construct an object of type *error\_code*.

### Parameters

**mode** – The parameter *mode* specifies whether the constructed *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

### Throws

nothing –

explicit **error\_code**(*error* e, *throwmode* mode = *throwmode::plain*)

Construct an object of type *error\_code*.

### Parameters

- **e** – The parameter *e* holds the *hpx::error* code the new exception should encapsulate.
- **mode** – The parameter *mode* specifies whether the constructed *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

### Throws

nothing –

**error\_code**(*error* e, char const \**func*, char const \**file*, long *line*, *throwmode* mode = *throwmode::plain*)

Construct an object of type *error\_code*.

### Parameters

- **e** – The parameter *e* holds the *hpx::error* code the new exception should encapsulate.
- **func** – The name of the function where the error was raised.
- **file** – The file name of the code where the error was raised.
- **line** – The line number of the code line where the error was raised.
- **mode** – The parameter *mode* specifies whether the constructed *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

### Throws

nothing –

**error\_code**(*error* e, char const \**msg*, *throwmode* mode = *throwmode::plain*)

Construct an object of type *error\_code*.

### Parameters

- **e** – The parameter *e* holds the *hpx::error* code the new exception should encapsulate.
- **msg** – The parameter *msg* holds the error message the new exception should encapsulate.
- **mode** – The parameter *mode* specifies whether the constructed *hpx::error\_code* belongs to the error category *hpx\_category* (if *mode* is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if *mode* is *rethrow*).

### Throws

*std::bad\_alloc* – (if allocation of a copy of the passed string fails).

**error\_code**(*error* e, char const \*msg, char const \*func, char const \*file, long line, *throwmode* mode = *throwmode::plain*)

Construct an object of type *error\_code*.

**Parameters**

- **e** – The parameter **e** holds the *hpx::error* code the new exception should encapsulate.
- **msg** – The parameter **msg** holds the error message the new exception should encapsulate.
- **func** – The name of the function where the error was raised.
- **file** – The file name of the code where the error was raised.
- **line** – The line number of the code line where the error was raised.
- **mode** – The parameter **mode** specifies whether the constructed *hpx::error\_code* belongs to the error category *hpx\_category* (if mode is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if mode is *rethrow*).

**Throws**

*std::bad\_alloc* – (if allocation of a copy of the passed string fails).

**error\_code**(*error* e, *std::string* const &msg, *throwmode* mode = *throwmode::plain*)

Construct an object of type *error\_code*.

**Parameters**

- **e** – The parameter **e** holds the *hpx::error* code the new exception should encapsulate.
- **msg** – The parameter **msg** holds the error message the new exception should encapsulate.
- **mode** – The parameter **mode** specifies whether the constructed *hpx::error\_code* belongs to the error category *hpx\_category* (if mode is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if mode is *rethrow*).

**Throws**

*std::bad\_alloc* – (if allocation of a copy of the passed string fails).

**error\_code**(*error* e, *std::string* const &msg, char const \*func, char const \*file, long line, *throwmode* mode = *throwmode::plain*)

Construct an object of type *error\_code*.

**Parameters**

- **e** – The parameter **e** holds the *hpx::error* code the new exception should encapsulate.
- **msg** – The parameter **msg** holds the error message the new exception should encapsulate.
- **func** – The name of the function where the error was raised.
- **file** – The file name of the code where the error was raised.
- **line** – The line number of the code line where the error was raised.
- **mode** – The parameter **mode** specifies whether the constructed *hpx::error\_code* belongs to the error category *hpx\_category* (if mode is *plain*, this is the default) or to the category *hpx\_category\_rethrow* (if mode is *rethrow*).

**Throws**

*std::bad\_alloc* – (if allocation of a copy of the passed string fails).

**error\_code**(*error\_code*&&) = default

*error\_code* &**operator**=(*error\_code*&&) = default

**~error\_code**() = default

*std::string* **get\_message**() const

Return a reference to the error message stored in the *hpx::error\_code*.

**Throws**

nothing –

inline void **clear**()

Clear this *error\_code* object. The postconditions of invoking this method are.

- `value() == hpx::error::success` and `category() == hpx::get_hpx_category()`

**error\_code**(*error\_code* const &rhs)

Copy constructor for *error\_code*

---

**Note:** This function maintains the error category of the left hand side if the right hand side is a success code.

---

*error\_code* &**operator=**(*error\_code* const &rhs)

Assignment operator for *error\_code*

---

**Note:** This function maintains the error category of the left hand side if the right hand side is a success code.

---

## **hpx::execution::experimental::persistent\_auto\_chunk\_size**

Defined in header [hpx/execution.hpp](#)<sup>724</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace execution
```

### **Typedefs**

```
    typedef hpx::execution::experimental::persistent_auto_chunk_size instead
```

```
    namespace experimental
```

```
        struct persistent_auto_chunk_size
```

```
            #include <persistent_auto_chunk_size.hpp> Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.
```

---

<sup>724</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/execution.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/execution.hpp)

## Public Functions

```
inline explicit constexpr persistent_auto_chunk_size(std::uint64_t const
                                                    num_iters_for_timing = 0) noexcept
```

Construct an `persistent_auto_chunk_size` executor parameters object

---

**Note:** Default constructed `persistent_auto_chunk_size` executor parameter types will use 0 microseconds as the execution time for each chunk and 80 microseconds as the minimal time for which any of the scheduled chunks should run.

---

```
inline explicit persistent_auto_chunk_size(hpx::chrono::steady_duration const &time_cs,
                                           std::uint64_t const num_iters_for_timing = 0)
                                           noexcept
```

Construct an `persistent_auto_chunk_size` executor parameters object

### Parameters

- **time\_cs** – The execution time for each chunk.
- **num\_iters\_for\_timing** – [in] The number of iterations to use for measuring the execution time of one iteration

```
inline persistent_auto_chunk_size(hpx::chrono::steady_duration const &time_cs,
                                  hpx::chrono::steady_duration const &rel_time,
                                  std::uint64_t const num_iters_for_timing = 0)
                                  noexcept
```

Construct an `persistent_auto_chunk_size` executor parameters object

### Parameters

- **rel\_time** – [in] The time duration to use as the minimum to decide how many loop iterations should be combined.
- **time\_cs** – The execution time for each chunk.
- **num\_iters\_for\_timing** – [in] The number of iterations to use for measuring the execution time of one iteration

## hpx::execution::experimental::collect\_chunking\_parameters

Defined in header `hpx/execution.hpp`<sup>725</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
    namespace execution
```

```
        namespace experimental
```

```

```

*#include <collect\_chunking\_parameters.hpp>* Collect various parameters used for running a parallel algorithm.

## Public Functions

```
inline explicit constexpr collect_chunking_parameters(chunking_parameters
                                                         &exec_params) noexcept
```

## hpx/execution/executors/default\_parameters.hpp

Defined in header `hpx/execution/executors/default_parameters.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace execution
```

```
        namespace experimental
```

```
            struct default_parameters
```

*#include <default\_parameters.hpp>* Loop iterations are divided into pieces of size *chunk\_size* and then assigned to threads. If *chunk\_size* is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

---

**Note:** This executor parameters type is equivalent to OpenMP's `STATIC` scheduling directive.

---

## Public Functions

**default\_parameters()** = default

Construct a default\_parameters executor parameters object

---

**Note:** By default, the number of loop iterations is determined from the number of available cores and the overall number of loop iterations to schedule.

---

## hpx/execution/executors/adaptive\_static\_chunk\_size.hpp

Defined in header hpx/execution/executors/adaptive\_static\_chunk\_size.hpp.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

namespace **experimental**

struct **adaptive\_static\_chunk\_size**

*#include <adaptive\_static\_chunk\_size.hpp>* Loop iterations are divided into pieces of size *chunk\_size* and then assigned to threads. If *chunk\_size* is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

---

**Note:** This executor parameters type is equivalent to OpenMP's STATIC scheduling directive.

---

## Public Functions

**adaptive\_static\_chunk\_size()** = default

Construct a adaptive\_static\_chunk\_size executor parameters object

---

**Note:** By default the number of loop iterations is determined from the number of available cores and the overall number of loop iterations to schedule.

---

inline explicit constexpr **adaptive\_static\_chunk\_size**(std::size\_t const chunk\_size)  
noexcept

Construct a adaptive\_static\_chunk\_size executor parameters object

### Parameters

**chunk\_size** – [in] The optional chunk size to use as the number of loop iterations to run on a single thread.

## hpx::execution::experimental::dynamic\_chunk\_size

Defined in header [hpx/execution.hpp](#)<sup>726</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace execution
```

```
        namespace experimental
```

```
            struct dynamic_chunk_size
```

```
                #include <dynamic_chunk_size.hpp> Loop iterations are divided into pieces of size chunk_size and then dynamically scheduled among the threads; when a thread finishes one chunk, it is dynamically assigned another. If chunk_size is not specified, the default chunk size is 1.
```

---

**Note:** This executor parameters type is equivalent to OpenMP's DYNAMIC scheduling directive.

---

### Public Functions

**dynamic\_chunk\_size()** = default

Construct an `dynamic_chunk_size` executor parameters object

---

**Note:** Default constructed `dynamic_chunk_size` executor parameter types will use a chunk size of '1'.

---

```
inline explicit constexpr dynamic_chunk_size(std::size_t chunk_size) noexcept
```

Construct a `dynamic_chunk_size` executor parameters object

#### Parameters

**chunk\_size** – [in] The optional chunk size to use as the number of loop iterations to schedule together. The default chunk size is 1.

## hpx/execution/executors/execution.hpp

Defined in header `hpx/execution/executors/execution.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

*#include <execution\_parameters\_fwd.hpp>* Collect various parameters of the chunking for this parallel algorithm execution

---

**Note:** This calls `params.mark_begin_execution(exec)` if it exists; otherwise it does nothing.

---

**Param params**

[in] The executor parameters object to use as a fallback if the executor does not expose

**Param exec**

[in] The executor object which will be used for scheduling of the loop iterations.

**Param num\_elements**

[in] The overall number of elements for the algorithm.

**Param num\_cores**

[in] The overall number of cores to utilize for the algorithm.

**Param num\_chunks**

[in] The overall number of chunks for the algorithm.

**Param chunk\_size**

[in] The size of the chunks created for the algorithm.

## Public Functions

template<typename **Parameters**, typename **Executor**>

inline decltype(auto) **operator()**(*Parameters* &&params, *Executor* &&exec, *std::size\_t* num\_elements, *std::size\_t* num\_cores, *std::size\_t* num\_chunks, *std::size\_t* chunk\_size) const

struct **get\_chunk\_size\_t**

*#include <execution\_parameters\_fwd.hpp>* Return the number of invocations of the given function *f* which should be combined into a single task

**Param params**

[in] The executor parameters object to use for determining the chunk size for the given number of tasks *num\_tasks*.

**Param exec**

[in] The executor object which will be used for scheduling of the loop iterations.

**Param iteration\_duration**

[in] The time one of the tasks require to be executed.

**Param cores**

[in] The number of cores the number of chunks should be determined for.

**Param num\_tasks**

[in] The number of tasks the chunk size should be determined for

**Return**

The size of the chunks (number of iterations per chunk) that should be used for parallel execution.

## Public Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) operator() (Parameters &&params, Executor &&exec,
                                   hpx::chrono::steady_duration const &iteration_duration,

```

```
struct mark_partition_t
```

```
#include <execution_parameters_fwd.hpp> Mark custom point in parallel algorithm execution
```

---

**Note:** This calls `params.mark_partition(exec, partition, args...)` if it exists; otherwise it does nothing.

---

**Param params**

[in] The executor parameters object to use as a fallback if the executor does not expose

**Param exec**

[in] The executor object which will be used for scheduling of the loop iterations.

## Public Functions

```
template<typename Parameters, typename Executor, typename ...Args>
inline decltype(auto) operator()(Parameters &&params, Executor &&exec, std::size_t
                                partition, Args&&... args) const
```

```
struct maximal_number_of_chunks_t
```

```
#include <execution_parameters_fwd.hpp> Return the largest reasonable number of chunks to
create for a single algorithm invocation.
```

**Param params**

[in] The executor parameters object to use for determining the number of chunks for the given number of *cores*.

**Param exec**

[in] The executor object which will be used for scheduling of the loop iterations.

**Param cores**

[in] The number of cores the number of chunks should be determined for.

**Param num\_tasks**

[in] The number of tasks the chunk size should be determined for

## Public Functions

```
template<typename Parameters, typename Executor>
inline decltype(auto) operator()(Parameters &&params, Executor &&exec, std::size_t cores,
                                   std::size_t num_tasks) const
```

```
struct measure_iteration_t
```

*#include <execution\_parameters\_fwd.hpp>* Return the measured execution time for one iteration based on running the given function.

---

**Note:** The parameter *f* is expected to be a nullary function returning a `std::size_t` representing the number of iteration the function has already executed (i.e. which don't have to be scheduled anymore).

---

### Param params

[in] The executor parameters object to use for determining the chunk size for the given number of tasks *num\_tasks*.

### Param exec

[in] The executor object which will be used for scheduling of the loop iterations.

### Param f

[in] The function which will be optionally scheduled using the given executor.

### Param num\_tasks

[in] The number of tasks the chunk size should be determined for

### Return

The execution time for one of the tasks.

## Public Functions

```
template<typename Parameters, typename Executor, typename F>
inline decltype(auto) operator()(Parameters &&params, Executor &&exec, F &&f,
                                   std::size_t num_tasks) const
```

```
struct null_parameters_t
```

```
struct processing_units_count_t
```

*#include <execution\_parameters\_fwd.hpp>* Retrieve the number of (kernel-)threads used by the associated executor.

---

**Note:** This calls `params.processing_units_count(Executor&&)` if it exists; otherwise it forwards the request to the executor parameters object.

---

### Param params

[in] The executor parameters object to use as a fallback if the executor does not expose

### Param exec

[in] The executor object which will be used for scheduling of the loop iterations.

### Param iteration\_duration

[in] The time one of the tasks require to be executed.

### Param num\_tasks

[in] The number of tasks the number of cores should be determined for

**Return**

The number of cores to use

**Public Functions**

```
template<typename Parameters, typename Executor>

```
template<typename ExPolicy, typename Executor, typename Parameters>
```

```
struct rebind_executor
```

*#include <rebind\_executor.hpp>* Rebind the type of executor used by an execution policy. The execution category of *Executor* shall not be weaker than that of *ExecutionPolicy*.

## Public Types

```
using type = typename policy_type::template rebind<executor_type, parameters_type>::type
```

The type of the rebound execution policy.

## hpx::execution::experimental::static\_chunk\_size

Defined in header [hpx/execution.hpp](#)<sup>727</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
namespace execution
```

```
namespace experimental
```

```
struct static_chunk_size
```

*#include <static\_chunk\_size.hpp>* Loop iterations are divided into pieces of size *chunk\_size* and then assigned to threads. If *chunk\_size* is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

---

**Note:** This executor parameters type is equivalent to OpenMP's *STATIC* scheduling directive.

---

## Public Functions

```
static_chunk_size() = default
```

Construct a *static\_chunk\_size* executor parameters object

---

**Note:** By default, the number of loop iterations is determined from the number of available cores and the overall number of loop iterations to schedule.

---

```
inline explicit constexpr static_chunk_size(std::size_t const chunk_size) noexcept
```

Construct a *static\_chunk\_size* executor parameters object

---

<sup>727</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/execution.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/execution.hpp)

**Parameters**

**chunk\_size** – [in] The optional chunk size to use as the number of loop iterations to run on a single thread.

**hpx::execution::experimental::guided\_chunk\_size**

Defined in header [hpx/execution.hpp](#)<sup>728</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **execution**

namespace **experimental**

struct **guided\_chunk\_size**

*#include <guided\_chunk\_size.hpp>* Iterations are dynamically assigned to threads in blocks as threads request those until no blocks remain to be assigned. Similar to `dynamic_chunk_size` except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to *number\_of\_iterations / number\_of\_cores*. Subsequent blocks are proportional to *number\_of\_iterations\_remaining / number\_of\_cores*. The optional chunk size parameter defines the minimum block size. The default chunk size is 1.

---

**Note:** This executor parameters type is equivalent to OpenMP's GUIDED scheduling directive.

---

**Public Functions**

**guided\_chunk\_size**() = default

Construct an `dynamic_chunk_size` executor parameters object

---

**Note:** Default constructed `dynamic_chunk_size` executor parameter types will use a chunk size of '1'.

---

inline explicit constexpr **guided\_chunk\_size**(std::size\_t const min\_chunk\_size) noexcept

Construct a `guided_chunk_size` executor parameters object

**Parameters**

**min\_chunk\_size** – [in] The optional minimal chunk size to use as the minimal number of loop iterations to schedule together. The default minimal chunk size is 1.

---

<sup>728</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/execution.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/execution.hpp)

**hpx/execution/executors/execution\_information.hpp**

Defined in header `hpx/execution/executors/execution_information.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

**Variables**

constexpr struct `hpx::execution::experimental::has_pending_closures_t` **has\_pending\_closures**

constexpr struct `hpx::execution::experimental::get_pu_mask_t` **get\_pu\_mask**

constexpr struct `hpx::execution::experimental::set_scheduler_mode_t` **set\_scheduler\_mode**

struct **get\_pu\_mask\_t**

*#include <execution\_information.hpp>* Retrieve the bitmask describing the processing units the given thread is allowed to run on

All `threads::executors` invoke `sched.get_pu_mask()`.

---

**Note:** If the executor does not support this operation, this call will always invoke `hpx::threads::get_pu_mask()`

---

**Param exec**

[in] The executor object to use for querying the number of pending tasks.

**Param topo**

[in] The topology object to use to extract the requested information.

**Param threan\_num**

[in] The sequence number of the thread to retrieve information for.

**Public Functions**

template<typename **Executor**>

inline decltype(auto) **operator()** (*Executor* &&exec, *threads::topology* &topo, *std::size\_t* thread\_num) const

template<typename **Executor**>

inline decltype(auto) **operator()** (*Executor*&&, *threads::topology* &topo, *std::size\_t* thread\_num) const

struct **has\_pending\_closures\_t**

*#include <execution\_information.hpp>* Retrieve whether this executor has operations pending or not.

---

**Note:** If the executor does not expose this information, this call will always return *false*

---

**Param exec**

[in] The executor object to use to extract the requested information for.

**Public Functions**

template<typename **Executor**>  
inline decltype(auto) **operator()** (*Executor* &&exec) const

template<typename **Executor**>  
inline decltype(auto) **operator()** (*Executor*&&) const

struct **set\_scheduler\_mode\_t**

*#include <execution\_information.hpp>* Set various modes of operation on the scheduler underneath the given executor.

---

**Note:** This calls `exec.set_scheduler_mode(mode)` if it exists; otherwise it does nothing.

---

**Param exec**

[in] The executor object to use.

**Param mode**

[in] The new mode for the scheduler to pick up

**Public Functions**

template<typename **Executor**, typename **Mode**>  
inline void **operator()** (*Executor* &&exec, *Mode* const &mode) const

template<typename **Executor**, typename **Mode**>  
inline void **operator()** (*Executor*&&, *Mode* const&) const

## **hpx::execution::experimental::max\_num\_chunks**

Defined in header `hpx/execution.hpp`<sup>729</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

---

<sup>729</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/execution.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/execution.hpp)

namespace **experimental**

struct **max\_num\_chunks**

*#include <max\_num\_chunks.hpp>* Loop iterations are divided into not more than *num\_chunks* partitions that are assigned to threads. If *num\_chunks* is not specified, the number of chunks is determined based on the number of available cores.

### Public Functions

**max\_num\_chunks()** = default

Construct a max\_num\_chunks executor parameters object

---

**Note:** By default, the number of chunks is determined from the number of available cores.

---

inline explicit constexpr **max\_num\_chunks**(std::size\_t const num\_chunks) noexcept

Construct a max\_num\_chunks executor parameters object

#### Parameters

**num\_chunks** – [in] The optional number of chunks to use to run on a single thread.

## hpx::execution::experimental::num\_cores

Defined in header [hpx/execution.hpp](#)<sup>730</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

struct **num\_cores**

*#include <num\_cores.hpp>* Control number of cores in executors which need a functionality for setting the number of cores to be used by an algorithm directly

### Public Functions

inline explicit constexpr **num\_cores**(std::size\_t const cores = 1) noexcept

Construct a num\_cores executor parameters object

---

**Note:** make sure the minimal number of cores is and the maximum number of cores is what's available to HPX

---

<sup>730</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/execution.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/execution.hpp)

## hpx::execution::experimental::auto\_chunk\_size

Defined in header `hpx/execution.hpp`<sup>731</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
    namespace execution
```

```
        namespace experimental
```

```
            struct auto_chunk_size
```

```
                #include <auto_chunk_size.hpp> Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.
```

### Public Functions

```
inline explicit constexpr auto_chunk_size(std::uint64_t const num_iters_for_timing = 0)
                                         noexcept
```

Construct an auto\_chunk\_size executor parameters object

---

**Note:** Default constructed auto\_chunk\_size executor parameter types will use 80 microseconds as the minimal time for which any of the scheduled chunks should run.

---

```
inline explicit auto_chunk_size(hpx::chrono::steady_duration const &rel_time, std::uint64_t
                                const num_iters_for_timing = 0) noexcept
```

Construct an auto\_chunk\_size executor parameters object

#### Parameters

- **rel\_time** – [in] The time duration to use as the minimum to decide how many loop iterations should be combined.
- **num\_iters\_for\_timing** – [in] The number of iterations to use for the timing operation

## execution\_base

See *Public API* for a list of names and headers that are part of the public HPX API.

---

<sup>731</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/execution.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/execution.hpp)

**hpx/execution\_base/execution.hpp**

Defined in header `hpx/execution_base/execution.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

struct **parallel\_execution\_tag**

*#include <execution.hpp>* Function invocations executed by a group of parallel execution agents execute in unordered fashion. Any such invocations executing in the same thread are indeterminately sequenced with respect to each other.

---

**Note:** `parallel_execution_tag` is weaker than `sequenced_execution_tag`.

---

struct **sequenced\_execution\_tag**

*#include <execution.hpp>* Function invocations executed by a group of sequential execution agents execute in sequential order.

struct **unsequenced\_execution\_tag**

*#include <execution.hpp>* Function invocations executed by a group of vector execution agents are permitted to execute in unordered fashion when executed in different threads, and un-sequenced with respect to one another when executed in the same thread.

---

**Note:** `unsequenced_execution_tag` is weaker than `parallel_execution_tag`.

---

namespace **parallel**

namespace **execution**

**Variables**

constexpr struct `hpx::parallel::execution::sync_execute_t` **sync\_execute**

constexpr struct `hpx::parallel::execution::async_execute_t` **async\_execute**

constexpr struct `hpx::parallel::execution::then_execute_t` **then\_execute**

constexpr struct `hpx::parallel::execution::post_t` **post**

constexpr struct `hpx::parallel::execution::bulk_sync_execute_t` **bulk\_sync\_execute**

```
constexpr struct hpx::parallel::execution::bulk_async_execute_t bulk_async_execute
```

```
constexpr struct hpx::parallel::execution::bulk_then_execute_t bulk_then_execute
```

```
constexpr struct hpx::parallel::execution::async_invoke_t async_invoke
```

```
constexpr struct hpx::parallel::execution::sync_invoke_t sync_invoke
```

```
struct async_execute_t
```

*#include <execution.hpp>* Customization point for asynchronous execution agent creation.

This asynchronously creates a single function invocation *f*() using the associated executor.

---

**Note:** Executors have to implement only `async_execute()`. All other functions will be emulated by this or other customization points in terms of this single basic primitive. However, some executors will naturally specialize all operations for maximum efficiency.

---

---

**Note:** This is valid for one way executors (calls `make_ready_future(exec.sync_execute(f, ts...))` if it exists) and for two-way executors (calls `exec.async_execute(f, ts...)` if it exists).

---

**Param *exec***

[in] The executor object to use for scheduling of the function *f*.

**Param *f***

[in] The function which will be scheduled using the given executor.

**Param *ts***

[in] Additional arguments to use to invoke *f*.

**Return**

*f*(*ts...*)'s result through a future

## Public Functions

```
template<typename Executor, typename F, typename ...Ts>  
inline decltype(auto) operator() (Executor &&exec, F &&f, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename ...Ts>  
inline decltype(auto) operator() (Executor &&exec, F &&f, Ts&&... ts) const
```

```
struct async_invoke_t
```

*#include <execution.hpp>* Asynchronously invoke the given set of nullary functions, each on its own execution agent

This creates a group of function invocations whose ordering is given by the `execution_category` associated with the executor.

All exceptions thrown by invocations of the functions are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This calls `exec.async_invoke(fs...)` if it exists; otherwise it executes `async_execute(fs)` for each `fs`.

---

**Param exec**

[in] The executor object to use for scheduling of the functions `fs`.

**Param fs**

[in] The functions which will be scheduled using the given executor.

**Return**

The return type of `executor_type::async_invoke` if defined by `executor_type`. Otherwise, a `future<void>` representing finishing the execution of all functions `fs`.

**Public Functions**

```
template<typename Executor, typename F, typename ...Fs>
inline decltype(auto) operator() (Executor &&exec, F &&f, Fs&&... fs) const
```

```
template<executor_any Executor, typename F, typename ...Fs>
inline decltype(auto) operator() (Executor &&exec, F &&f, Fs&&... fs) const
```

```
struct bulk_async_execute_t
```

```
#include <execution.hpp> Bulk form of asynchronous execution agent creation.
```

This asynchronously creates a group of function invocations `f(i)` whose ordering is given by the `execution_category` associated with the executor.

Here *i* takes on all values in the index space implied by `shape`. All exceptions thrown by invocations of `f(i)` are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This is deliberately different from the `bulk_async_execute` customization points specified in P0443. The `bulk_async_execute` customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

---

---

**Note:** This calls `exec.bulk_async_execute(f, shape, ts...)` if it exists; otherwise it executes `async_execute(f, shape, ts...)` as often as needed.

---

**Param exec**

[in] The executor object to use for scheduling of the function `f`.

**Param f**

[in] The function which will be scheduled using the given executor.

**Param shape**

[in] The shape objects which defines the iteration boundaries for the arguments to be passed to `f`.

**Param ts**

[in] Additional arguments to use to invoke `f`.

**Return**

The return type of `executor_type::bulk_async_execute` if defined by `executor_type`. Otherwise, a vector of futures holding the returned values of each invocation of `f`.

## Public Functions

```
template<typename Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Ts&&... ts)
    const
```

```
template<typename Executor, typename F, typename Shape, typename ...Ts>
inline auto operator() (Executor &&exec, F &&f, Shape const &shape, Ts&&... ts) const ->
    decltype(HPX_FORWARD(Executor,
        exec).bulk_async_execute(HPX_FORWARD(F, f), shape,
        HPX_FORWARD(Ts, ts)...))
```

```
template<executor_any Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Ts&&... ts)
    const
```

```
template<executor_any Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Ts&&... ts)
    const
```

struct **bulk\_sync\_execute\_t**

*#include <execution.hpp>* Bulk form of synchronous execution agent creation.

This synchronously creates a group of function invocations  $f(i)$  whose ordering is given by the `execution_category` associated with the executor. The function synchronizes the execution of all scheduled functions with the caller.

Here  $i$  takes on all values in the index space implied by `shape`. All exceptions thrown by invocations of  $f(i)$  are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This is deliberately different from the `bulk_sync_execute` customization points specified in P0443. The `bulk_sync_execute` customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

---

---

**Note:** This calls `exec.bulk_sync_execute(f, shape, ts...)` if it exists; otherwise it executes `sync_execute(f, shape, ts...)` as often as needed.

---

### Param `exec`

[in] The executor object to use for scheduling of the function  $f$ .

### Param `f`

[in] The function which will be scheduled using the given executor.

### Param `shape`

[in] The shape objects which defines the iteration boundaries for the arguments to be passed to  $f$ .

### Param `ts`

[in] Additional arguments to use to invoke  $f$ .

### Return

The return type of `executor_type::bulk_sync_execute` if defined by `executor_type`. Otherwise, a vector holding the returned values of each invocation of  $f$  except when  $f$  returns void, which case void is returned.

## Public Functions

```
template<typename Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Ts&&... ts)
    const
```

```
template<executor_any Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Ts&&... ts)
    const
```

```
template<executor_any Executor, typename F, typename Shape, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Ts&&... ts)
    const
```

```
struct bulk_then_execute_t
```

*#include <execution.hpp>* Bulk form of execution agent creation depending on a given future.

This creates a group of function invocations  $f(i)$  whose ordering is given by the `execution_category` associated with the executor.

Here  $i$  takes on all values in the index space implied by `shape`. All exceptions thrown by invocations of  $f(i)$  are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This is deliberately different from the `then_sync_execute` customization points specified in P0443. The `bulk_then_execute` customization point defined here is more generic and is used as the workhorse for implementing the specified APIs.

---

---

**Note:** This calls `exec.bulk_then_execute(f, shape, pred, ts...)` if it exists; otherwise it executes `sync_execute(f, shape, pred.share(), ts...)` (if this executor is also an `OneWayExecutor`), or `async_execute(f, shape, pred.share(), ts...)` (if this executor is also a `TwoWayExecutor`) - as often as needed.

---

### Param `exec`

[in] The executor object to use for scheduling of the function  $f$ .

### Param `f`

[in] The function which will be scheduled using the given executor.

### Param `shape`

[in] The shape objects which defines the iteration boundaries for the arguments to be passed to  $f$ .

### Param `predecessor`

[in] The future object the execution of the given function depends on.

### Param `ts`

[in] Additional arguments to use to invoke  $f$ .

### Return

The return type of `executor_type::bulk_then_execute` if defined by `executor_type`. Otherwise, a vector holding the returned values of each invocation of  $f$ .

### Public Functions

```
template<typename Executor, typename F, typename Shape, typename Future, typename  
...Ts>  
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Future  
    &&predecessor, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename Shape, typename Future, typename  
...Ts>  
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Future  
    &&predecessor, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename Shape, typename Future, typename  
...Ts>  
inline decltype(auto) operator() (Executor &&exec, F &&f, Shape const &shape, Future  
    &&predecessor, Ts&&... ts) const
```

struct **post\_t**

*#include <execution.hpp>* Customization point for asynchronous fire & forget execution agent creation.

This asynchronously (fire & forget) creates a single function invocation *f*() using the associated executor.

---

**Note:** This is valid for two-way executors (calls *exec.post(f, ts...)*, if available, otherwise it calls *exec.async\_execute(f, ts...)* while discarding the returned future), and for non-blocking two-way executors (calls *exec.post(f, ts...)* if it exists).

---

#### Param *exec*

[in] The executor object to use for scheduling of the function *f*.

#### Param *f*

[in] The function which will be scheduled using the given executor.

#### Param *ts*

[in] Additional arguments to use to invoke *f*.

### Public Functions

```
template<typename Executor, typename F, typename ...Ts>  
inline decltype(auto) operator() (Executor &&exec, F &&f, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename ...Ts>  
inline decltype(auto) operator() (Executor &&exec, F &&f, Ts&&... ts) const
```

struct **sync\_execute\_t**

*#include <execution.hpp>* Customization point for synchronous execution agent creation.

This synchronously creates a single function invocation *f*() using the associated executor. The execution of the supplied function synchronizes with the caller

---

**Note:** It will call *exec.sync\_execute(f, ts...)* if the executor exposes a corresponding member function. For two-way executors it will invoke *async\_execute* and wait for the task's completion

---

before returning.

---

**Param exec**

[in] The executor object to use for scheduling of the function *f*.

**Param f**

[in] The function which will be scheduled using the given executor.

**Param ts**

[in] Additional arguments to use to invoke *f*.

**Return**

*f*(*ts...*)'s result

## Public Functions

```
template<typename Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Ts&&... ts) const
```

struct **sync\_invoke\_t**

*#include <execution.hpp>* Synchronously invoke the given set of nullary functions, each on its own execution agent

This creates a group of function invocations whose ordering is given by the *execution\_category* associated with the executor.

All exceptions thrown by invocations of the functions are reported in a manner consistent with parallel algorithm execution through the returned future.

---

**Note:** This calls *exec.sync\_invoke(fs...)* if it exists; otherwise it executes *sync\_execute(fs)* for each *fs*.

---

**Param exec**

[in] The executor object to use for scheduling of the functions *fs*.

**Param fs**

[in] The functions which will be scheduled using the given executor.

**Return**

The return type of *executor\_type::async\_invoke* if defined by *executor\_type*.

## Public Functions

```
template<typename Executor, typename F, typename ...Fs>
inline decltype(auto) operator() (Executor &&exec, F &&f, Fs&&... fs) const
```

```
template<executor_any Executor, typename F, typename ...Fs>
inline decltype(auto) operator() (Executor &&exec, F &&f, Fs&&... fs) const
```

struct **then\_execute\_t**

*#include <execution.hpp>* Customization point for execution agent creation depending on a given future.

This creates a single function invocation `f()` using the associated executor after the given future object has become ready.

---

**Note:** This is valid for two-way executors (calls `exec.then_execute(f, predecessor, ts...)` if it exists) and for one way executors (calls `predecessor.then(bind(f, ts...))`).

---

**Param `exec`**

[in] The executor object to use for scheduling of the function `f`.

**Param `f`**

[in] The function which will be scheduled using the given executor.

**Param `predecessor`**

[in] The future object the execution of the given function depends on.

**Param `ts`**

[in] Additional arguments to use to invoke `f`.

**Return**

`f(ts...)`'s result through a future

## Public Functions

```
template<typename Executor, typename F, typename Future, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Future &&predecessor, Ts&&...
                                   ts) const
```

```
template<executor_any Executor, typename F, typename Future, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, F &&f, Future &&predecessor, Ts&&...
                                   ts) const
```

namespace **hpx**

namespace **execution**

### Typedefs

```
using sequenced_task_policy = detail::sequenced_task_policy_shim<sequenced_executor,  
hpx::traits::executor_parameters_type_t<sequenced_executor>>
```

Extension: The class `sequenced_task_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may not be parallelized (has to run sequentially).

The algorithm returns a future representing the result of the corresponding algorithm when invoked with the `sequenced_policy`.

```
using sequenced_policy = detail::sequenced_policy_shim<sequenced_executor,  
hpx::traits::executor_parameters_type_t<sequenced_executor>>
```

The class `sequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm's execution may not be parallelized.

```
using parallel_task_policy = detail::parallel_task_policy_shim<parallel_executor,  
hpx::traits::executor_parameters_type_t<parallel_executor>>
```

Extension: The class `parallel_task_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

The algorithm returns a future representing the result of the corresponding algorithm when invoked with the `parallel_policy`.

```
using parallel_policy = detail::parallel_policy_shim<parallel_executor,  
hpx::traits::executor_parameters_type_t<parallel_executor>>
```

The class `parallel_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

```
using parallel_unsequenced_task_policy =  
detail::parallel_unsequenced_task_policy_shim<parallel_executor,  
hpx::traits::executor_parameters_type_t<parallel_executor>>
```

The class `parallel_unsequenced_task_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized and vectorized.

```
using parallel_unsequenced_policy =  
detail::parallel_unsequenced_policy_shim<parallel_executor,  
hpx::traits::executor_parameters_type_t<parallel_executor>>
```

The class `parallel_unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized and vectorized.

```
using unsequenced_task_policy = detail::unsequenced_task_policy_shim<sequenced_executor,  
hpx::traits::executor_parameters_type_t<sequenced_executor>>
```

The class `unsequenced_task_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be vectorized.

```
using unsequenced_policy = detail::unsequenced_policy_shim<sequenced_executor,  
hpx::traits::executor_parameters_type_t<sequenced_executor>>
```

The class `unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be vectorized.

## Variables

```

```

## Typedefs

```
typedef hpx::execution::parallel_executor instead  
  
namespace this_thread
```

## Functions

*hpx::execution::parallel\_executor* **get\_executor**(*error\_code* &ec = *throws*)

Returns a reference to the executor that was used to create the current thread.

### Throws

If – &ec != &throws, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw a *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

namespace **threads**

## Functions

*hpx::execution::parallel\_executor* **get\_executor**(*thread\_id\_type* const &id, *error\_code* &ec = *throws*)

Returns a reference to the executor that was used to create the given thread.

### Throws

If – &ec != &throws, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw a *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

### **hpx/executors/parallel\_executor\_aggregated.hpp**

### hpx/executors/std\_execution\_policy.hpp

Defined in header `hpx/executors/std_execution_policy.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/executors/execution\_policy\_parameters.hpp

Defined in header `hpx/executors/execution_policy_parameters.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/executors/thread\_pool\_continues\_on\_sender.hpp

Defined in header `hpx/executors/thread_pool_continues_on_sender.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Domain-optimized `continues_on` sender for HPX thread pool schedulers.

When `stdexec::continues_on` is applied with an HPX `thread_pool_scheduler`, the generic `stdexec` implementation creates two operation states: one for the source sender and one for the scheduler hop (`schedule_from`). This double-state overhead adds ~1 us per task in microbenchmarks.

This header provides a custom sender that replaces the generic path by:

1. Connecting the source sender to a lightweight receiver that captures the downstream receiver and the scheduler.
2. On `set_value`: if we are already on the same HPX thread pool, forwarding inline; otherwise, posting a single HPX task to forward the values.

This eliminates the intermediate `__storage_for_t`, the second operation state, and the `run_loop` overhead.

```
namespace hpx
```

```
    namespace execution
```

```
        namespace experimental
```

### **hpx/executors/executor\_scheduler.hpp**

```
namespace hpx
```

```
    namespace execution
```

```
        namespace experimental
```

```
            template<typename Executor>
```

```
            struct executor_scheduler
```

### **hpx/executors/datapar/execution\_policy.hpp**

Defined in header `hpx/executors/datapar/execution_policy.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### **hpx/executors/datapar/execution\_policy\_mappings.hpp**

Defined in header `hpx/executors/datapar/execution_policy_mappings.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## **filesystem**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### **hpx/filesystem/api.hpp**

Defined in header `hpx/filesystem/api.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

This file provides a compatibility layer using Boost.Filesystem for the C++17 filesystem library. It is *not* intended to be a complete compatibility layer. It only contains functions required by the HPX codebase. It also provides some functions only available in Boost.Filesystem when using C++17 filesystem.

namespace **hpx**

namespace **filesystem**

### Functions

inline path **initial\_path**()

inline *std::string* **to\_string**(path const &p)

inline *std::string* **basename**(path const &p)

inline path **canonical**(path const &p, path const &base)

inline path **canonical**(path const &p, path const &base, *std::error\_code* &ec)

namespace **filesystem**

### functional

See *Public API* for a list of names and headers that are part of the public HPX API.

### **hpx::invoke\_fused**, **hpx::invoke\_fused\_r**

Defined in header [hpx/functional.hpp](#)<sup>733</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level namespace.

### Functions

template<typename **F**, typename **Tuple**>

constexpr detail::invoke\_fused\_result\_t<*F*, *Tuple*> **invoke\_fused**(*F* &&*f*, *Tuple* &&*t*) noexcept(  
 cept(noexcept(detail::invoke\_fused\_impl(detail::fused\_index,  
 HPX\_FORWARD(*F*, *f*),  
 HPX\_FORWARD(*Tuple*, *t*))))

Invokes the given callable object *f* with the content of the sequenced type *t* (tuples, pairs).

---

**Note:** This function is similar to `std::apply` (C++17). The difference between `hpx::invoke` and `hpx::invoke_fused` is that the later unpacks the tuples while the former cannot. Turning a tuple into a parameter pack is not a trivial operation which makes `hpx::invoke_fused` rather useful.

---

### Parameters

---

<sup>733</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

- **f** – Must be a callable object. If **f** is a member function pointer, the first argument in the sequenced type will be treated as the callee (this object).
- **t** – A type whose contents are accessible through a call to `hpx::get`.

**Throws**

`std::exception` – like objects thrown by call to object **f** with the arguments contained in the sequenceable type **t**.

**Returns**

The result of the callable object when it's called with the content of the given sequenced type.

```
template<typename R, typename F, typename Tuple>
constexpr R invoke_fused_r(F &&f, Tuple &&t) noexcept
    {
        cept(noexcept(detail::invoke_fused_impl(detail::fused_index_pack_t<Tuple>{ },
        HPX_FORWARD(F, f), HPX_FORWARD(Tuple, t))))
    }
```

Invokes the given callable object **f** with the content of the sequenced type **t** (tuples, pairs).

---

**Note:** This function is similar to `std::apply` (C++17). The difference between `hpx::invoke` and `hpx::invoke_fused` is that the later unpacks the tuples while the former cannot. Turning a tuple into a parameter pack is not a trivial operation which makes `hpx::invoke_fused` rather useful.

---

---

**Note:** The difference between `hpx::invoke_fused` and `hpx::invoke_fused_r` is that the later allows to specify the return type as well.

---

**Parameters**

- **f** – Must be a callable object. If **f** is a member function pointer, the first argument in the sequenced type will be treated as the callee (this object).
- **t** – A type whose contents are accessible through a call to `hpx::get`.

**Throws**

`std::exception` – like objects thrown by call to object **f** with the arguments contained in the sequenceable type **t**.

**Template Parameters**

**R** – The result type of the function when it's called with the content of the given sequenced type.

**Returns**

The result of the callable object when it's called with the content of the given sequenced type.

## **hpx::reference\_wrapper, hpx::ref, hpx::cref**

Defined in header `hpx/functionnal.hpp`<sup>734</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```

## hpx::bind\_back

Defined in header [hpx/functional.hpp](#)<sup>735</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level namespace.

### Functions

```
template<typename F, typename ...Ts>
constexpr hpx::detail::bound_back<std::decay_t<F>, util::make_index_pack_t<sizeof...(Ts)>, util::decay_unwrap_t<Ts>...> bind
```

Function templates `bind_back` generate a forwarding call wrapper for `f`. Calling this wrapper is equivalent to invoking `f` with its last `sizeof...(Ts)` parameters bound to `vs`.

#### Parameters

- **f** – Callable object (function object, pointer to function, reference to function, pointer to member function, or pointer to data member) that will be bound to some arguments
- **vs** – list of the arguments to bind to the last `sizeof...(Ts)` parameters of `f`

#### Returns

A function object of type `T` that is unspecified, except that the types of objects returned by two calls to `hpx::bind_back` with the same arguments are the same.

```
template<typename F>
constexpr std::decay_t<F> bind_back(F &&f)
```

namespace **serialization**

### Functions

```
template<typename Archive, typename F, typename ...Ts>
void serialize(Archive &ar, ::hpx::detail::bound_back<F, Ts...> &bound, unsigned int const version =
    0)
```

## hpx::mem\_fn

Defined in header [hpx/functional.hpp](#)<sup>736</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level namespace.

---

<sup>735</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

<sup>736</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

## Functions

```
template<typename M, typename C>
constexpr detail::mem_fn<M C::*> mem_fn(M C::* pm) noexcept
```

Function template `hpx::mem_fn` generates wrapper objects for pointers to members, which can store, copy, and invoke a pointer to member. Both references and pointers (including smart pointers) to an object can be used when invoking a `hpx::mem_fn`.

### Parameters

**pm** – pointer to member that will be wrapped

### Returns

a call wrapper of unspecified type with the following member:

```
template <typename... Ts>
constexpr typename util::invoke_result_t<MemberPointer, Ts...>::type
operator()(Ts&&... vs) noexcept;
```

Let `fn` be the call wrapper returned by a call to `hpx::mem_fn` with a pointer to member `pm`. Then the expression `fn(t,a2,...,aN)` is equivalent to `HPX_INVOKE(pm,t,a2,...,aN)`. Thus, the return type of `operator()` is `std::result_of<decltype(pm)(Ts&&...)>::type` or equivalently `std::invoke_result_t<decltype(pm),Ts&&...>`, and the value in `noexcept` specifier is equal to `std::is_nothrow_invocable_v<decltype(pm),Ts&&...>`. Each argument in `vs` is perfectly forwarded, as if by `std::forward<Ts>(vs)...`.

```
template<typename R, typename C, typename ...Ps>
constexpr detail::mem_fn<R (C::*)(Ps...)> mem_fn(R (C::* pm)(Ps...)) noexcept
```

Function template `hpx::mem_fn` generates wrapper objects for pointers to members, which can store, copy, and invoke a pointer to member. Both references and pointers (including smart pointers) to an object can be used when invoking a `hpx::mem_fn`.

### Parameters

**pm** – pointer to member that will be wrapped

### Returns

a call wrapper of unspecified type with the following member:

```
template <typename... Ts>
constexpr typename util::invoke_result_t<MemberPointer, Ts...>::type
operator()(Ts&&... vs) noexcept;
```

Let `fn` be the call wrapper returned by a call to `hpx::mem_fn` with a pointer to member `pm`. Then the expression `fn(t,a2,...,aN)` is equivalent to `HPX_INVOKE(pm,t,a2,...,aN)`. Thus, the return type of `operator()` is `std::result_of<decltype(pm)(Ts&&...)>::type` or equivalently `std::invoke_result_t<decltype(pm),Ts&&...>`, and the value in `noexcept` specifier is equal to `std::is_nothrow_invocable_v<decltype(pm),Ts&&...>`. Each argument in `vs` is perfectly forwarded, as if by `std::forward<Ts>(vs)...`.

```
template<typename R, typename C, typename ...Ps>
constexpr detail::mem_fn<R (C::*)(Ps...) const> mem_fn(R (C::* pm)(Ps...) const) noexcept
```

Function template `hpx::mem_fn` generates wrapper objects for pointers to members, which can store, copy, and invoke a pointer to member. Both references and pointers (including smart pointers) to an object can be used when invoking a `hpx::mem_fn`.

**Parameters**

**pm** – pointer to member that will be wrapped

**Returns**

a call wrapper of unspecified type with the following member:

```
template <typename... Ts>
constexpr typename util::invoke_result<MemberPointer, Ts...>::type
operator()(Ts&&... vs) noexcept;
```

Let `fn` be the call wrapper returned by a call to `hpx::mem_fn` with a pointer to member `pm`. Then the expression `fn(t,a2,...,aN)` is equivalent to `HPX_INVOKE(pm,t,a2,...,aN)`. Thus, the return type of `operator()` is `std::result_of<decltype(pm)(Ts&&...)>::type` or equivalently `std::invoke_result_t<decltype(pm),Ts&&...>`, and the value in `noexcept` specifier is equal to `std::is_nothrow_invocable_v<decltype(pm),Ts&&...>`. Each argument in `vs` is perfectly forwarded, as if by `std::forward<Ts>(vs)...`.

**hpx::function\_ref**

Defined in header `hpx/functionality.hpp`<sup>737</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level namespace.

template<typename **Sig**>

class **function\_ref**

`#include <function_ref.hpp>` **function\_ref** class is a vocabulary type with reference semantics for passing entities to call.

An example use case that benefits from higher-order functions is `retry(n, f)` which attempts to call `f` up to `n` times synchronously until success. This example might model the real-world scenario of repeatedly querying a flaky web service.

```
using payload = std::optional< /* ... */ >;
// Repeatedly invokes `action` up to `times` repetitions.
// Immediately returns if `action` returns a valid `payload`.
// Returns `std::nullopt` otherwise.
payload retry(size_t times, /* ????? */ action);
```

The passed-in action should be a callable entity that takes no arguments and returns a payload. This can be done with function pointers, `hpx::function` or a template but it is much simpler with `function_ref` as seen below:

```
payload retry(size_t times, function_ref<payload()> action);
```

template<typename **R**, typename ...**Ts**>

class **function\_ref**<**R**(**Ts**...)>

<sup>737</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functionality.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functionality.hpp)

## Public Functions

```

template<typename F, typename FD = std::decay_t<F>, typename Enable =
std::enable_if_t<!std::is_same_v<FD, function_ref> && is_invocable_r_v<R, F&, Ts...>>>
inline function_ref(F &&f)

inline function_ref(function_ref const &other) noexcept

template<typename F, typename FD = std::decay_t<F>, typename Enable =
std::enable_if_t<!std::is_same_v<FD, function_ref> && is_invocable_r_v<R, F&, Ts...>>>
inline function_ref &operator=(F &&f)

inline function_ref &operator=(function_ref const &other) noexcept

template<typename F, typename T = std::remove_reference_t<F>, typename Enable =
std::enable_if_t<!std::is_pointer_v<T>>>
inline void assign(F &&f)

template<typename T>
inline void assign(std::reference_wrapper<T> f_ref) noexcept

template<typename T>
inline void assign(T *f_ptr) noexcept

inline void swap(function_ref &f) noexcept

inline R operator()(Ts... vs) const

inline std::size_t get_function_address() const

inline char const *get_function_annotation() const

inline hpx::tracing::annotation_handle get_function_annotation_tracing() const

```

## Protected Attributes

```
R (*vp_ptr)(void*, Ts&&...)
```

```
void *object
```

## Private Types

```
using VTable = util::detail::function_ref_vtable<R(Ts...)>
```

### Private Static Functions

```
template<typename T>
static inline constexpr VTable const *get_vtable() noexcept
```

```
namespace util
```

### **hpx::bind\_front**

Defined in header `hpx/functional.hpp`<sup>738</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

Top level namespace.

### Functions

```
template<typename F, typename ...Ts>
constexpr detail::bound_front<std::decay_t<F>, util::make_index_pack_t<sizeof...(Ts)>, util::decay_unwrap_t<Ts>...> bind_front(F &&f, Ts...)
```

Function template `bind_front` generates a forwarding call wrapper for `f`. Calling this wrapper is equivalent to invoking `f` with its first `sizeof...(Ts)` parameters bound to `vs`.

#### Parameters

- **f** – Callable object (function object, pointer to function, reference to function, pointer to member function, or pointer to data member) that will be bound to some arguments
- **vs** – list of the arguments to bind to the first or `sizeof...(Ts)` parameters of `f`

#### Returns

A function object of type `T` that is unspecified, except that the types of objects returned by two calls to `hpx::bind_front` with the same arguments are the same.

```
template<typename F>
constexpr std::decay_t<F> bind_front(F &&f)
```

```
namespace serialization
```

---

<sup>738</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

## Functions

```

void serialize(Archive &ar, ::hpx::detail::bound_front<F, Ts...> &bound, unsigned int const version =
    0)
```

### hpx::move\_only\_function

Defined in header [hpx/functional.hpp](#)<sup>739</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level namespace.

```
template<typename Sig, bool Serializable = false>
```

```
class move_only_function
```

*#include <move\_only\_function.hpp>* Class template *hpx::move\_only\_function* is a general-purpose polymorphic function wrapper. *hpx::move\_only\_function* objects can store and invoke any constructible (not required to be move constructible) Callable target [§8212](#); functions, lambda expressions, bind expressions, or other function objects, as well as pointers to member functions and pointers to member objects.

The stored callable object is called the target of *hpx::move\_only\_function*. If an *hpx::move\_only\_function* contains no target, it is called empty. Unlike *hpx::function*, invoking an empty *hpx::move\_only\_function* results in undefined behavior.

*hpx::move\_only\_function*s supports every possible combination of cv-qualifiers, ref-qualifiers, and noexcept-specifiers not including volatile provided in its template parameter. These qualifiers and specifier (if any) are added to its operator(). *hpx::move\_only\_function* satisfies the requirements of MoveConstructible and MoveAssignable, but does not satisfy CopyConstructible or CopyAssignable.

```
template<typename R, typename ...Ts, bool Serializable>
```

```
class move_only_function<R(Ts...), Serializable> : public util::detail::basic_function<R(Ts...), false,
    Serializable>
```

## Public Types

template<typename Sig>

using function = hpx::function<Sig, true>
```

**hpx::bind**, **hpx::placeholders::\_1**, **hpx::placeholders::\_2**, ..., **hpx::placeholders::\_9**

Defined in header `hpx/functionality.hpp`<sup>741</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

Top level namespace.

<sup>741</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functionality.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functionality.hpp)

## Functions

```
template<typename F, typename ...Ts>
constexpr detail::bound<std::decay_t<F>, util::make_index_pack_t<sizeof...(Ts)>, util::decay_unwrap_t<Ts>...> bind(F
&&f,
Ts&&...
vs)
```

The function template *bind* generates a forwarding call wrapper for *f*. Calling this wrapper is equivalent to invoking *f* with some of its arguments bound to *vs*.

### Parameters

- **f** – Callable object (function object, pointer to function, reference to function, pointer to member function, or pointer to data member) that will be bound to some arguments
- **vs** – list of arguments to bind, with the unbound arguments replaced by the placeholders `_1, _2, _3...` of namespace `hpx::placeholders`

### Returns

A function object of unspecified type *T*, for which

`hpx::is_bind_expression<T>::value == true.`

## namespace **placeholders**

The `hpx::placeholders` namespace contains the placeholder objects `[_1, ..., _N]` where *N* is an implementation defined maximum number.

When used as an argument in a `hpx::bind` expression, the placeholder objects are stored in the generated function object, and when that function object is invoked with unbound arguments, each placeholder `_N` is replaced by the corresponding *N*th unbound argument.

The types of the placeholder objects are `DefaultConstructible` and `CopyConstructible`, their default copy/move constructors do not throw exceptions, and for any placeholder `_N`, the type `hpx::is_placeholder<decltype(_N)>` is defined, where `hpx::is_placeholder<decltype(_N)>` is derived from `std::integral_constant<int, N>`.

## Variables

```
constexpr detail::placeholder<1> _1 = { }
```

```
constexpr detail::placeholder<2> _2 = { }
```

```
constexpr detail::placeholder<3> _3 = { }
```

```
constexpr detail::placeholder<4> _4 = { }
```

```
constexpr detail::placeholder<5> _5 = { }
```

```
constexpr detail::placeholder<6> _6 = { }
```

```
constexpr detail::placeholder<7> _7 = { }
```

```
constexpr detail::placeholder<8> _8 = { }
```

```
constexpr detail::placeholder<9> _9 = { }
```

```
namespace serialization
```

## Functions

```
template<typename Archive, typename F, typename ...Ts>
void serialize(Archive &ar, ::hpx::detail::bound<F, Ts...> &bound, unsigned int const version = 0)
```

```
template<typename Archive, std::size_t I>
constexpr void serialize(Archive&, ::hpx::detail::placeholder<I>&, unsigned int const = 0) noexcept
```

## hpx::is\_placeholder

Defined in header [hpx/functional.hpp](#)<sup>742</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

Top level namespace.

```
template<typename T>
```

```
struct is_placeholder
```

*#include <is\_placeholder.hpp>* If T is a standard, Boost, or HPX placeholder (`_1`, `_2`, `_3`, ...) then this template is derived from `std::integral_constant<int,1>`, `std::integral_constant<int,2>`, `std::integral_constant<int,3>`, respectively. Otherwise, it is derived from `std::integral_constant<int,0>`.

The template may be specialized for any user-defined T type: the specialization must satisfy *UnaryTypeTrait* with base characteristic of `std::integral_constant<int,N>` with N>0 to indicate that T should be treated as N'th placeholder type. `hpx::bind` uses `hpx::is_placeholder` to detect placeholders for unbound arguments.

## hpx::is\_bind\_expression

Defined in header [hpx/functional.hpp](#)<sup>743</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

Top level namespace.

<sup>742</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

<sup>743</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

## Variables

```
template<typename T>
```

```
constexpr bool is_bind_expression_v = is_bind_expression<T>::value
```

```
template<typename T>
```

```
struct is_bind_expression : public std::is_bind_expression<T>
```

*#include <is\_bind\_expression.hpp>* If T is the type produced by a call to *hpx::bind*, this template is derived from *std::true\_type*. For any other type, this template is derived from *std::false\_type*.

This template may be specialized for a user-defined type T to implement *UnaryTypeTrait* with base characteristic of *std::true\_type* to indicate that T should be treated by *hpx::bind* as if it were the type of a bind subexpression: when a bind-generated function object is invoked, a bound argument of this type will be invoked as a function object and will be given all the unbound arguments passed to the bind-generated object.

Subclassed by *hpx::is\_bind\_expression< T const >*

```
template<typename T>
```

```
struct is_bind_expression<T const> : public hpx::is_bind_expression<T>
```

## **hpx::experimental::scope\_exit**

Defined in header *hpx/experimental/scope.hpp*.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level namespace.

namespace **experimental**

## Functions

```
template<typename F>
```

```
auto scope_exit(F &&f)
```

The class template *scope\_exit* is a general-purpose scope guard intended to call its exit function when a scope is exited.

### Template Parameters

**F** – type of stored exit function

### Parameters

**f** – stored exit function

## hpx::experimental::scope\_fail

Defined in header `hpx/experimental/scope.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level namespace.

namespace **experimental**

### Functions

```
template<typename F>
auto scope_fail(F &&f)
```

The class template `scope_fail` is a general-purpose scope guard intended to call its exit function when a scope is exited via an exception.

#### Template Parameters

**F** – type of stored exit function

#### Parameters

**f** – stored exit function

## hpx::experimental::scope\_success

Defined in header `hpx/experimental/scope.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level namespace.

namespace **experimental**

### Functions

```
template<typename F>
auto scope_success(F &&f)
```

The class template `scope_success` is a general-purpose scope guard intended to call its exit function when a scope is normally exited.

#### Template Parameters

**F** – type of stored exit function

#### Parameters

**f** – stored exit function

## futures

See *Public API* for a list of names and headers that are part of the public *HPX* API.

**hpx::future,**        **hpx::shared\_future,**        **hpx::make\_future,**        **hpx::make\_shared\_future,**  
**hpx::make\_ready\_future,**        **hpx::make\_ready\_future\_alloc,**        **hpx::make\_ready\_future\_at,**  
**hpx::make\_ready\_future\_after,** **hpx::make\_exceptional\_future**

Defined in header `hpx/future.hpp`<sup>744</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

## Functions

template<typename **R**, typename **U**>  
`hpx::future<R> make_future(hpx::future<U> &&f)`  
Converts any future of type **U** to any other future of type **R** based on an existing conversion path from **U** to **R**.

template<typename **R**, typename **U**, typename **Conv**>  
`hpx::future<R> make_future(hpx::future<U> &&f, Conv &&conv)`  
Converts any future of type **U** to any other future of type **R** based on a given conversion function: **R** conv(**U**).

template<typename **R**, typename **U**>  
`hpx::future<R> make_future(hpx::shared_future<U> f)`  
Converts any *shared\_future* of type **U** to any other future of type **R** based on an existing conversion path from **U** to **R**.

template<typename **R**, typename **U**, typename **Conv**>  
`hpx::future<R> make_future(hpx::shared_future<U> f, Conv &&conv)`  
Converts any future of type **U** to any other future of type **R** based on an existing conversion path from **U** to **R**.

template<typename **R**>  
`hpx::shared_future<R> make_shared_future(hpx::future<R> &&f) noexcept`  
Converts any future or *shared\_future* of type **T** to a corresponding *shared\_future* of type **T**.

template<typename **R**>  
`hpx::shared_future<R> &make_shared_future(hpx::shared_future<R> &f) noexcept`  
Converts any future or *shared\_future* of type **T** to a corresponding *shared\_future* of type **T**.

template<typename **R**>  
`hpx::shared_future<R> &&make_shared_future(hpx::shared_future<R> &&f) noexcept`  
Converts any future or *shared\_future* of type **T** to a corresponding *shared\_future* of type **T**.

template<typename **R**>  
`hpx::shared_future<R> const &make_shared_future(hpx::shared_future<R> const &f) noexcept`  
Converts any future or *shared\_future* of type **T** to a corresponding *shared\_future* of type **T**.

template<typename **T**, typename **Allocator**, typename ...**Ts**>

---

<sup>744</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

```
std::enable_if_t<std::is_constructible_v<T, Ts&&...> || std::is_void_v<T>, future<T>> make_ready_future_alloc(Allocator const
&a,
Ts&&...
ts)
```

Creates a pre-initialized future object with allocator (extension)

```
template<typename T, typename ...Ts>
std::enable_if_t<std::is_constructible_v<T, Ts&&...> || std::is_void_v<T>, future<T>> make_ready_future(Ts&&...
ts)
```

The function creates a shared state that is immediately ready and returns a future associated with that shared state. For the returned future, `valid() == true` and `is_ready() == true`.

```
template<int DeductionGuard = 0, typename Allocator, typename T>
future<hpx::util::decay_unwrap_t<T>> make_ready_future_alloc(Allocator const &a, T &&init)
```

```
template<int DeductionGuard = 0, typename T>
future<hpx::util::decay_unwrap_t<T>> make_ready_future(T &&init)
```

The function creates a shared state that is immediately ready and returns a future associated with that shared state. For the returned future, `valid() == true` and `is_ready() == true`.

```
template<typename T>
future<T> make_exceptional_future(std::exception_ptr const &e)
```

Creates a pre-initialized future object which holds the given error (extension)

```
template<typename T, typename E>
future<T> make_exceptional_future(E e)
```

Creates a pre-initialized future object which holds the given error (extension)

```
template<int DeductionGuard = 0, typename T>
future<hpx::util::decay_unwrap_t<T>> make_ready_future_at(hpx::chrono::steady_time_point const
&abs_time, T &&init)
```

Creates a pre-initialized future object which gets ready at a given point in time (extension)

```
template<int DeductionGuard = 0, typename T>
future<hpx::util::decay_unwrap_t<T>> make_ready_future_after(hpx::chrono::steady_duration const
&rel_time, T &&init)
```

Creates a pre-initialized future object which gets ready after a given point in time (extension)

```
template<typename Allocator>
inline future<void> make_ready_future_alloc(Allocator const &a)
```

```
future<void> make_ready_future()
```

The function creates a shared state that is immediately ready and returns a future associated with that shared state. For the returned future, `valid() == true` and `is_ready() == true`.

```
inline future<void> make_ready_future_at(hpx::chrono::steady_time_point const &abs_time)
```

Creates a pre-initialized future object which gets ready at a given point in time (extension)

```
inline future<void> make_ready_future_after(hpx::chrono::steady_duration const &rel_time)
```

Creates a pre-initialized future object which gets ready after a given point in time (extension)

```
template<typename R>
```

```
class future : public hpx::lcos::detail::future_base<future<R>, R>
```

`#include <future_fwd.hpp>` The class template `hpx::future` provides a mechanism to access the result of asynchronous operations:

- An asynchronous operation (created via `hpx::async`, `hpx::packaged_task`, or `hpx::promise`) can provide a `hpx::future` object to the creator of that asynchronous operation.
- The creator of the asynchronous operation can then use a variety of methods to query, wait for, or extract a value from the `hpx::future`. These methods may block if the asynchronous operation has not yet provided a value.
- When the asynchronous operation is ready to send a result to the creator, it can do so by modifying shared state (e.g. `hpx::promise::set_value`) that is linked to the creator's `hpx::future`. Note that `hpx::future` references shared state that is not shared with any other asynchronous return objects (as opposed to `hpx::shared_future`).

## Public Types

using **result\_t\_type** = *R*

using **shared\_state\_type** = *base\_type::shared\_state\_type*

## Public Functions

constexpr **future**() noexcept = default

**future**(*future* &&other) noexcept = default

**future**(*future* const &other) noexcept = delete

inline **future**(*future*<*future*> &&other) noexcept

inline **future**(*future*<*shared\_future*<*R*>> &&other) noexcept

template<typename **T**>

inline **future**(*future*<*T*> &&other, *std::enable\_if\_t<std::is\_void\_v<R> && !traits::is\_future\_v<T>, T>\** = nullptr) noexcept

**~future**() = default

*future* &**operator**=(*future* &&other) noexcept = default

*future* &**operator**=(*future* const &other) noexcept = delete

inline *shared\_future*<*R*> **share**() noexcept

inline *hpx::traits::future\_traits*<*future*>::result\_type **get**()

inline *hpx::traits::future\_traits*<*future*>::result\_type **get**(*error\_code* &ec)

template<typename **F**>

inline decltype(auto) **then**(*F* &&*f*, *error\_code* &ec = *throws*)

Attaches a continuation to *\*this*. The behavior is undefined if *\*this* has no associated shared state (i.e., *valid()==false* ).

In cases where *decltype(func(\*this))* is *future*<*R*>, the resulting type is *future*<*R*> instead of *future*<*future*<*R*>>. Effects:

- The continuation is called when the object's shared state is ready (has a value or exception stored).
- The continuation launches according to the specified launch policy or executor.

- When the executor or launch policy is not provided the continuation inherits the parent's launch policy or executor.
- If the parent was created with `std::promise` or with a `packaged_task` (has no associated launch policy), the continuation behaves the same as the third overload with a policy argument of `launch::async` | `launch::deferred` and the same argument for `func`.
- If the parent has a policy of `launch::deferred` and the continuation does not have a specified launch policy or scheduler, then the parent is filled by immediately calling `.wait()`, and the policy of the antecedent is `launch::deferred`

---

**Note:** Postcondition:

- The future object is moved to the parameter of the continuation function.
  - `valid() == false` on original future object immediately after it returns.
- 

#### Template Parameters

**F** – The type of the function/function object to use (deduced). **F** must meet requirements of *MoveConstructible*.

#### Parameters

- **f** – A continuation to be attached.
- **ec** – Used to hold error code value originated during the operation. Defaults to `throws` &#8212; A special 'throw on error' `error_code`.

#### Returns

An object of type `future<decltype(func(*this))>` that refers to the shared state created by the continuation.

```
template<typename T0, typename F>
```

```
inline decltype(auto) then(T0 &&t0, F &&f, error_code &ec = throws)
```

Attaches a continuation to `*this`. The behavior is undefined if `*this` has no associated shared state (i.e., `valid() == false`). \copydetail `hpx::future::then(F&& f, error_code& ec = throws)`

---

**Note:** Postcondition:

- The future object is moved to the parameter of the continuation function.
  - `valid() == false` on original future object immediately after it returns.
- 

#### Template Parameters

- **T0** – The type of executor or launch policy.
- **F** – The type of the function/function object to use (deduced). **F** must meet requirements of *MoveConstructible*.

#### Parameters

- **t0** – The executor or launch policy to be used.
- **f** – A continuation to be attached.
- **ec** – Used to hold error code value originated during the operation. Defaults to `throws` &#8212; A special 'throw on error' `error_code`.

#### Returns

An object of type `future<decltype(func(*this))>` that refers to the shared state created by the continuation.

```
template<typename Allocator, typename F>
```

```
inline auto then_alloc(Allocator const &alloc, F &&f, error_code &ec = throws) ->
```

```
    decltype(base_type::then_alloc(alloc, std::move(*this), std::forward<F>(f),  
    ec))
```

## Private Types

```
using base_type = lcos::detail::future_base<future<R>, R>
```

## Private Functions

```
inline explicit future(hpx::intrusive_ptr<shared_state_type> const &state)
```

```
inline explicit future(hpx::intrusive_ptr<shared_state_type> &&state)
```

```
template<typename SharedState>
```

```
inline explicit future(hpx::intrusive_ptr<SharedState> const &state)
```

## Friends

```
friend struct hpx::traits::future_access
```

```
template<typename R>
```

```
class shared_future : public hpx::lcos::detail::future_base<shared_future<R>, R>
```

*#include <future\_fwd.hpp>* The class template *hpx::shared\_future* provides a mechanism to access the result of asynchronous operations, similar to *hpx::future*, except that multiple threads are allowed to wait for the same shared state. Unlike *hpx::future*, which is only moveable (so only one instance can refer to any particular asynchronous result), *hpx::shared\_future* is copyable and multiple shared future objects may refer to the same shared state. Access to the same shared state from multiple threads is safe if each thread does it through its own copy of a *shared\_future* object.

## Public Types

```
using result_type = R
```

```
using shared_state_type = base_type::shared_state_type
```

## Public Functions

```

!traits::is_future_v<T>, T>* = nullptr)
```

```
~shared_future() = default
```

---

```
shared_future &operator=(shared_future const &other) = default
```

```
shared_future &operator=(shared_future &&other) noexcept = default
```

```
inline hpx::traits::future_traits<shared_future>::result_type get() const
```

```
inline hpx::traits::future_traits<shared_future>::result_type get(error_code &ec) const
```

```
template<typename F>
```

```
inline decltype(auto) then(F &&f, error_code &ec = throws) const
```

Attaches a continuation to *\*this*. The behavior is undefined if *\*this* has no associated shared state (i.e., *valid() == false* ).

In cases where *decltype(func(\*this))* is *future<R>*, the resulting type is *future<R>* instead of *future<future<R>>*. Effects:

- The continuation is called when the object's shared state is ready (has a value or exception stored).
- The continuation launches according to the specified launch policy or executor.
- When the executor or launch policy is not provided the continuation inherits the parent's launch policy or executor.
- If the parent was created with *std::promise* or with a *packaged\_task* (has no associated launch policy), the continuation behaves the same as the third overload with a policy argument of *launch::async* | *launch::deferred* and the same argument for *func*.
- If the parent has a policy of *launch::deferred* and the continuation does not have a specified launch policy or scheduler, then the parent is filled by immediately calling *.wait()*, and the policy of the antecedent is *launch::deferred*

---

**Note:** Postcondition:

- The future object is moved to the parameter of the continuation function.
  - *valid() == false* on original future object immediately after it returns.
- 

#### Template Parameters

**F** – The type of the function/function object to use (deduced). *F* must meet requirements of *MoveConstructible*.

#### Parameters

- **f** – A continuation to be attached.
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special 'throw on error' *error\_code*.

#### Returns

An object of type *future<decltype(func(\*this))>* that refers to the shared state created by the continuation.

```
template<typename T0, typename F>
```

```
inline decltype(auto) then(T0 &&t0, F &&f, error_code &ec = throws) const
```

Attaches a continuation to *\*this*. The behavior is undefined if *\*this* has no associated shared state (i.e., *valid() == false* ). \copydetail *hpx::future::then*(*F* && *f*, *error\_code* & *ec* = *throws*)

---

**Note:** Postcondition:

- The future object is moved to the parameter of the continuation function.
  - *valid() == false* on original future object immediately after it returns.
- 

#### Template Parameters

## hpx::packaged\_task

Defined in header `hpx/future.hpp`<sup>745</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
template<typename Sig, typename Allocator>
```

```
struct uses_allocator<hpx::packaged_task<Sig>, Allocator> : public true_type
```

```
namespace hpx
```

```
    Top level HPX namespace.
```

```
    template<typename Sig>
```

```
        class packaged_task
```

```
            #include <packaged_task.hpp> The class template hpx::packaged_task wraps any Callable` target (function, lambda expression, bind expression, or another function object) so that it can be invoked asynchronously. Its return value or exception thrown is stored in a shared state which can be accessed through hpx::future objects. Just like hpx::function, hpx::packaged_task is a polymorphic, allocator-aware container: the stored callable target may be allocated on heap or with a provided allocator.
```

```
        template<typename R, typename ...Ts>
```

```
            class packaged_task<R(Ts...)>
```

### Public Functions

```

## **hpx/futures/future\_fwd.hpp**

Defined in header `hpx/futures/future_fwd.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

Top level HPX namespace.

```
template<typename R>
```

```
class future : public hpx::lcos::detail::future_base<future<R>, R>
```

```
    #include <future_fwd.hpp>
```

```
template<typename R>
```

```
class promise
```

*#include* <*promise.hpp*> The class template *hpx::promise* provides a facility to store a value or an exception that is later acquired asynchronously via a *hpx::future* object created by the *hpx::promise* object. Note that the *hpx::promise* object is meant to be used only once. Each promise is associated with a shared state, which contains some state information and a result which may be not yet evaluated, evaluated to a value (possibly void) or evaluated to an exception. A promise may do three things with the shared state:

- make ready: the promise stores the result or the exception in the shared state. Marks the state ready and unblocks any thread waiting on a future associated with the shared state.
- release: the promise gives up its reference to the shared state. If this was the last such reference, the shared state is destroyed. Unless this was a shared state created by *hpx::async* which is not yet ready, this operation does not block.

- **abandon**: the promise stores the exception of type `hpx::future_error` with error code `hpx::error::broken_promise`, makes the shared state ready, and then releases it. The promise is the “push” end of the promise-future communication channel: the operation that stores a value in the shared state synchronizes-with (as defined in `hpx::memory_order`) the successful return from any function that is waiting on the shared state (such as `hpx::future::get`). Concurrent access to the same shared state may conflict otherwise: for example multiple callers of `hpx::shared_future::get` must either all be read-only or provide external synchronization.

```
template<typename R>
```

```
class shared_future : public hpx::lcos::detail::future_base<shared_future<R>, R>  
    #include <future_fwd.hpp>
```

```
namespace lcos
```

```
namespace lcos
```

## hpx::promise

Defined in header [hpx/future.hpp](#)<sup>746</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
template<typename R, typename Allocator>
```

```
struct uses_allocator<hpx::promise<R>, Allocator> : public true_type

## io\_service

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/io\_service/io\_service\_pool.hpp

Defined in header `hpx/io_service/io_service_pool.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
namespace util
```

```
class io_service_pool
```

```
#include <io_service_pool.hpp> A pool of io_service objects.
```

### Public Functions

```
explicit io_service_pool(std::size_t pool_size = 2, threads::policies::callback_notifier const
                        &notifier = threads::policies::callback_notifier(), char const
                        *pool_name = "", char const *name_postfix = "")
```

Construct the `io_service` pool.

#### Parameters

- **pool\_size** – [in] The number of threads to run to serve incoming requests
- **notifier** – [in]
- **pool\_name** – [in]
- **name\_postfix** – [in]

```
explicit io_service_pool(threads::policies::callback_notifier const &notifier, char const
                        *pool_name = "", char const *name_postfix = "")
```

Construct the `io_service` pool.

#### Parameters

- **notifier** – [in]
- **pool\_name** – [in]
- **name\_postfix** – [in]

```
io_service_pool(io_service_pool const&) = delete
```

```
io_service_pool(io_service_pool&&) = delete
```

```
io_service_pool &operator=(io_service_pool const&) = delete
```

*io\_service\_pool* &**operator**=(*io\_service\_pool*&&) = delete

**~io\_service\_pool**()

bool **run**(bool join\_threads = true, *barrier* \*startup = nullptr) const

Run all *io\_service* objects in the pool. If *join\_threads* is true this will also wait for all threads to complete

bool **run**(*std::size\_t* num\_threads, bool join\_threads = true, *barrier* \*startup = nullptr) const

Run all *io\_service* objects in the pool. If *join\_threads* is true this will also wait for all threads to complete

void **stop**() const

Stop all *io\_service* objects in the pool.

void **join**() const

Join all *io\_service* threads in the pool.

void **clear**() const

Clear all internal data structures.

void **wait**() const

Wait for all work to be done.

bool **stopped**() const

*::asio::io\_context* &**get\_io\_service**(int index = -1) const

Get an *io\_service* to use.

*std::thread* &**get\_os\_thread\_handle**(*std::size\_t* thread\_num) const

access underlying thread handle

*std::size\_t* **size**() const noexcept

Get number of threads associated with this I/O service.

void **thread\_run**(*std::size\_t* index, *barrier* \*startup = nullptr) const

Activate the thread *index* for this thread pool.

char const \***get\_name**() const noexcept

Return name of this pool.

void **init**(*std::size\_t* pool\_size) const

## **hpx::lcos::local::and\_gate**

Defined in header `hpx/modules/lcos_local.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
    namespace lcos
```

```
        namespace local
```

```
struct and_gate : public hpx::lcos::local::base_and_gate<hpx::no_mutex>
    #include <and_gate.hpp> An AND-gate synchronization primitive that fires once all of its expected inputs have been received.
```

---

**Note:** This type is not thread-safe. It has to be protected from concurrent access by different threads by the code using instances of this type.

---

## Public Functions

```
inline explicit and_gate(std::size_t const count = 0)
```

Construct an *and\_gate* from the number of participants to synchronize the control flow with.

### Parameters

**count** – The number of inputs that need to be received before the gate is triggered.

```
and_gate(and_gate const&) = delete
```

*and\_gate* is not copyable nor is it copy-assignable.

```
and_gate &operator=(and_gate const&) = delete
```

```
and_gate(and_gate &&rhs) = default
```

*and\_gate* is movable and move-assignable.

```
and_gate &operator=(and_gate &&rhs) = default
```

```
~and_gate() = default
```

```
template<typename Lock, typename Ptr = std::nullptr_t>
```

```
inline hpx::future<void> get_future(Lock &l, Ptr generation_value = nullptr, error_code &ec  
    = hpx::throws)
```

Get a future allowing to wait for the gate to fire.

### Template Parameters

- **Lock** – Type of the lock object used by the caller to protect the gate.
- **Ptr** – Type of the (optional) pointer used to receive the current generation value.

### Parameters

- **l** – The lock object that is currently holding the gate's associated (outer) lock.
- **generation\_value** – [out] Optional pointer to a variable that will receive the current generation value of the gate.
- **ec** – Used to hold error information if the operation fails.

### Returns

A future that becomes ready once the gate has fired.

```
template<typename Lock, typename Ptr = std::nullptr_t>
```

```
inline hpx::shared_future<void> get_shared_future(Lock &l, Ptr generation_value =  
    nullptr, error_code &ec = hpx::throws)
```

Get a shared future allowing to wait for the gate to fire.

### Template Parameters

- **Lock** – Type of the lock object used by the caller to protect the gate.
- **Ptr** – Type of the (optional) pointer used to receive the current generation value.

### Parameters

- **l** – The lock object that is currently holding the gate's associated (outer) lock.
- **generation\_value** – [out] Optional pointer to a variable that will receive the current generation value of the gate.

- **ec** – Used to hold error information if the operation fails.

**Returns**

A shared future that becomes ready once the gate has fired.

```
template<typename Lock, typename F = std::nullptr_t>
inline bool set(std::size_t which, Lock &l, F &&f = nullptr, error_code &ec = hpx::throws)
```

Set the data which has to go into the segment **which**.

**Template Parameters**

- **Lock** – Type of the lock object used by the caller to protect the gate.
- **F** – Type of the (optional) callback function invoked once the gate is triggered.

**Parameters**

- **which** – The zero-based index of the segment (input) to set.
- **l** – The lock object that is currently holding the gate’s associated (outer) lock.
- **f** – Optional callback that is invoked, with **l** held, when this call causes the gate to fire.
- **ec** – Used to hold error information if the operation fails.

**Returns**

**true** if this call caused the gate to fire (i.e. all inputs have now been received), **false** otherwise.

```
template<typename Lock>
inline void synchronize(std::size_t generation_value, Lock &l, char const *function_name =
    "and_gate::synchronize", error_code &ec = throws)
```

Wait for the generational counter to reach the requested stage.

**Template Parameters**

**Lock** – Type of the lock object used by the caller to protect the gate.

**Parameters**

- **generation\_value** – The generation the caller waits for the gate to reach.
- **l** – The lock object that is currently holding the gate’s associated (outer) lock.
- **function\_name** – The name to be used for error reporting.
- **ec** – Used to hold error information if the operation fails.

**Private Types**

```
using base_type = base_and_gate<hpx::no_mutex>
```

```
template<typename Mutex = hpx::spinlock>
```

```
struct base_and_gate
```

*#include <and\_gate.hpp>* A gate that waits for a fixed number of participants to “arrive” before releasing all waiters (an AND-synchronization primitive).

The *base\_and\_gate* implements a synchronization construct similar to a countdown latch/barrier: it is initialized with a number of expected participants (“segments”). Each participant signals its arrival, and once all expected participants have arrived, futures obtained from *get\_future()* become ready and callbacks passed to *set()* are invoked.

After firing, the gate can be reused for subsequent synchronization rounds. The generation is advanced explicitly with *next\_generation()*. Callers can use the generation number to guard against stale/late notifications from a previous round.

---

**Note:** Not copyable, but movable. Moving invalidates the moved-from object’s generation (set to an invalid-generation sentinel).

---

---

**Note:** Typically used via `hpx::lcos::local::and_gate` rather than directly.

---

### Template Parameters

**Mutex** – The mutex type protecting internal state. Defaults to `hpx::spinlock`.

### Public Functions

inline explicit **base\_and\_gate**(*std::size\_t* const count = 0)

Construct a *base\_and\_gate* from the number of participants to synchronize the control flow with.

#### Parameters

**count** – The number of inputs that need to be received before the gate is triggered.

**base\_and\_gate**(*base\_and\_gate* const &rhs) = delete

*base\_and\_gate* is not copyable nor is it copy-assignable.

*base\_and\_gate* &**operator**=(*base\_and\_gate* const &rhs) = delete

inline **base\_and\_gate**(*base\_and\_gate* &&rhs) noexcept

Move-construct a *base\_and\_gate*, leaving *rhs* in a moved-from state.

#### Parameters

**rhs** – The *base\_and\_gate* to move from.

inline *base\_and\_gate* &**operator**=(*base\_and\_gate* &&rhs) noexcept

Move-assign a *base\_and\_gate*, leaving *rhs* in a moved-from state.

#### Parameters

**rhs** – The *base\_and\_gate* to move from.

#### Returns

A reference to `*this`.

**~base\_and\_gate**() = default

template<typename **Ptr** = *std::nullptr\_t*>

inline *hpx::future*<void> **get\_future**(*Ptr* generation\_value = nullptr, *error\_code* &ec = *hpx::throws*)

Get a future allowing to wait for the gate to fire.

#### Template Parameters

**Ptr** – Type of the (optional) pointer used to receive the current generation value.

#### Parameters

- **generation\_value** – [out] Optional pointer to a variable that will receive the current generation value of the gate.
- **ec** – Used to hold error information if the operation fails.

#### Returns

A future that becomes ready once the gate has fired.

template<typename **Ptr** = *std::nullptr\_t*>

inline *hpx::shared\_future*<void> **get\_shared\_future**(*Ptr* generation\_value = nullptr, *error\_code* &ec = *hpx::throws*)

Get a shared future allowing to wait for the gate to fire.

#### Template Parameters

**Ptr** – Type of the (optional) pointer used to receive the current generation value.

#### Parameters

- **generation\_value** – [out] Optional pointer to a variable that will receive the current generation value of the gate.
- **ec** – Used to hold error information if the operation fails.

**Returns**

A shared future that becomes ready once the gate has fired.

```
template<typename F = std::nullptr_t>
inline bool set(std::size_t which, F &&f = nullptr, error_code &ec = throws)
```

Mark the segment **which** as received.

**Template Parameters**

**F** – Type of the (optional) callback function invoked once the gate is triggered.

**Parameters**

- **which** – The zero-based index of the segment (input) to set.
- **f** – Optional callback that is invoked, with the outer lock held, when this call causes the gate to fire.
- **ec** – Used to hold error information if the operation fails.

**Returns**

**true** if this call caused the gate to fire (i.e. all inputs have now been received), **false** otherwise.

```
inline void synchronize(std::size_t generation_value, char const *function_name =
                        "base_and_gate<>::synchronize", error_code &ec = throws)
```

Wait for the generational counter to reach the requested stage.

**Parameters**

- **generation\_value** – The generation the caller waits for the gate to reach.
- **function\_name** – The name to be used for error reporting.
- **ec** – Used to hold error information if the operation fails.

```
template<typename Lock>
inline std::size_t next_generation(Lock &l, std::size_t const new_generation =
                                   static_cast<std::size_t>(-1), error_code &ec = throws)
```

Advance the generational counter of the gate, unblocking any waiters whose requested generation has now been reached.

**Template Parameters**

**Lock** – Type of the lock object used by the caller to protect the gate; must already be locked when this overload is called.

**Parameters**

- **l** – The lock object that is currently holding the gate's associated (outer) lock.
- **new\_generation** – The generation value the gate's counter should be reset to before being advanced; if not given the gate is simply advanced to the next generation. The returned generation value is one beyond this value.
- **ec** – Used to hold error information if the operation fails.

**Returns**

The new generation value of the gate.

```
inline std::size_t next_generation(std::size_t new_generation = static_cast<std::size_t>(-1),
                                   error_code &ec = throws)
```

Advance the generational counter of the gate, unblocking any waiters whose requested generation has now been reached.

**Parameters**

- **new\_generation** – The generation value the gate's counter should be reset to before being advanced; if not given the gate is simply advanced to the next generation. The returned generation value is one beyond this value.
- **ec** – Used to hold error information if the operation fails.

**Returns**

The new generation value of the gate.

```
template<typename Lock>
inline std::size_t generation(Lock &l) const noexcept
```

Query the current generation value of the gate.

**Template Parameters**

**Lock** – Type of the lock object used by the caller to protect the gate; must already be locked when this overload is called.

**Parameters**

**l** – The lock object that is currently holding the gate’s associated (outer) lock.

**Returns**

The current generation value of the gate.

```
inline std::size_t generation() const noexcept
```

Query the current generation value of the gate.

**Returns**

The current generation value of the gate.

Defined in header `hpx/unwrap.hpp`<sup>747</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

## Functions

```
template<typename ...Args>
auto unwrap(Args&&... args) -> decltype(util::detail::unwrap_depth_impl<1U>(HPX_FORWARD(Args,
    args)...))
```

A helper function for retrieving the actual result of any `hpx::future` like type which is wrapped in an arbitrary way.

Unwraps the given pack of arguments, so that any `hpx::future` object is replaced by its future result type in the argument pack:

- `hpx::future<int> -> int`
- `hpx::future<std::vector<float>> -> std::vector<float>`
- `std::vector<future<float>> -> std::vector<float>`

The function is capable of unwrapping `hpx::future` like objects that are wrapped inside any container or tuple like type, see `hpx::util::map_pack()` for a detailed description about which surrounding types are supported. Non `hpx::future` like types are permitted as arguments and passed through.

```
hpx::unwrap(hpx::make_ready_future(0));

// Multiple arguments hpx::tuple<int, int> i2 =
    hpx::unwrap(hpx::make_ready_future(1),
        hpx::make_ready_future(2));
```

---

**Note:** This function unwraps the given arguments until the first traversed nested `hpx::future` which corresponds to an unwrapping depth of one. See `hpx::unwrap_n()` for a function which unwraps the given

---

<sup>747</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/unwrap.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/unwrap.hpp)

arguments to a particular depth or `hpx::unwrap_all()` that unwraps all future like objects recursively which are contained in the arguments.

#### Parameters

**args** – the arguments that are unwrapped which may contain any arbitrary future or non-future type.

#### Throws

`std::exception` – like objects in case any of the given wrapped `hpx::future` objects were resolved through an exception. See `hpx::future::get()` for details.

#### Returns

Depending on the count of arguments this function returns a `hpx::tuple` containing the unwrapped arguments if multiple arguments are given. In case the function is called with a single argument, the argument is unwrapped and returned.

```
template<std::size_t Depth, typename ...Args>
auto unwrap_n(Args&&... args) ->
    decltype(util::detail::unwrap_depth_impl<Depth>(HPX_FORWARD(Args, args)...))
```

An alternative version of `hpx::unwrap()`, which unwraps the given arguments to a certain depth of `hpx::future` like objects.

See `unwrap` for a detailed description.

#### Template Parameters

**Depth** – The count of `hpx::future` like objects which are unwrapped maximally.

```
template<typename ...Args>
auto unwrap_all(Args&&... args) ->
    decltype(util::detail::unwrap_depth_impl<0U>(HPX_FORWARD(Args, args)...))
```

An alternative version of `hpx::unwrap()`, which unwraps the given arguments recursively so that all contained `hpx::future` like objects are replaced by their actual value.

See `hpx::unwrap()` for a detailed description.

```
template<typename T>
auto unwrapping(T &&callable) ->
    decltype(util::detail::functional_unwrap_depth_impl<1U>(HPX_FORWARD(T, callable)))
```

Returns a callable object which unwraps its arguments upon invocation using the `hpx::unwrap()` function and then passes the result to the given callable object.

```
    return left + right;
});

int i1 = callable(hpx::make_ready_future(1),
                  hpx::make_ready_future(2));
```

See `hpx::unwrap()` for a detailed description.

#### Parameters

**callable** – the callable object which is called with the result of the corresponding `unwrap` function.

```
template<std::size_t Depth, typename T>
```

```
auto unwrapping_n(T &&callable) ->
    decltype(util::detail::functional_unwrap_depth_impl<Depth>(HPX_FORWARD(T,
        callable)))
```

Returns a callable object which unwraps its arguments upon invocation using the `hpx::unwrap_n()` function and then passes the result to the given callable object.

See `hpx::unwrapping()` for a detailed description.

```
template<typename T>
auto unwrapping_all(T &&callable) ->
    decltype(util::detail::functional_unwrap_depth_impl<0U>(HPX_FORWARD(T,
        callable)))
```

Returns a callable object which unwraps its arguments upon invocation using the `hpx::unwrap_all()` function and then passes the result to the given callable object.

See `hpx::unwrapping()` for a detailed description.

namespace **functional**

struct **unwrap**

*#include <unwrap.hpp>* A helper function object for functionally invoking `hpx::unwrap`. For more information please refer to its documentation.

struct **unwrap\_all**

*#include <unwrap.hpp>* A helper function object for functionally invoking `hpx::unwrap_all`. For more information please refer to its documentation.

template<std::size\_t **Depth**>

struct **unwrap\_n**

*#include <unwrap.hpp>* A helper function object for functionally invoking `hpx::unwrap_n`. For more information please refer to its documentation.

## hpx/pack\_traversal/pack\_traversal\_async.hpp

Defined in header `hpx/pack_traversal/pack_traversal_async.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

## Functions

```
template<typename Visitor, typename ...T>
auto traverse_pack_async(Visitor &&visitor, T&&... pack) ->
    decltype(detail::apply_pack_transform_async(HPX_FORWARD(Visitor,
        visitor), HPX_FORWARD(T, pack)...))
```

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus, we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```
// The synchronous overload is called for each object, // it may
// return false to suspend the current control. // In that case the
// overload below is called. template <typename T> bool
operator()(async_traverse_visit_tag, T&& element) {
    return true;
}

// The asynchronous overload this is called when the //
// synchronous overload returned false. // In addition to the
// current visited element the overload is // called with a
// continuation callable object which resumes the // traversal when
// it's called later. // The continuation next may be stored and
// called later or // dropped completely to abort the traversal
// early. template <typename T, typename N> void
operator()(async_traverse_detach_tag, T&& element, N&& next) { }

// The overload is called when the traversal was finished. // As
// argument the whole pack is passed over which we // traversed
// asynchronously. template <typename T> void
operator()(async_traverse_complete_tag, T&& pack) { }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.

### Parameters

- **visitor** – A visitor object which provides the three `operator()` overloads that were described above. Additionally, the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should have a virtual destructor!
- **pack** – The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.

### Returns

A `hpx::intrusive_ptr` that references an instance of the given visitor object.

## hpx/pack\_traversal/pack\_traversal.hpp

Defined in header `hpx/pack_traversal/pack_traversal.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

### Functions

```
template<typename Mapper, typename...  
T> < unspecified > map_pack (Mapper &&mapper, T &&... pack)
```

Maps the pack with the given mapper.

This function tries to visit all plain elements which may be wrapped in:

- homogeneous containers (`std::vector`, `std::list`)
- heterogeneous containers (`hpx::tuple`, `std::pair`, `std::array`) and re-assembles the pack with the result of the mapper. Mapping from one type to a different one is supported.

Elements that aren't accepted by the mapper are routed through and preserved through the hierarchy.

```
// Maps all integers to floats  
map_pack([](int value) {  
    return float(value);  
},  
1, hpx::make_tuple(2, std::vector<int>{3, 4}), 5);
```

#### Throws

`std::exception` – like objects which are thrown by an invocation to the mapper.

#### Parameters

- **mapper** – A callable object, which accept an arbitrary type and maps it to another type or the same one.
- **pack** – An arbitrary variadic pack which may contain any type.

#### Returns

The mapped element or in case the pack contains multiple elements, the pack is wrapped into a `hpx::tuple`.

## preprocessor

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## hpx/preprocessor/strip\_parens.hpp

Defined in header `hpx/preprocessor/strip_parens.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### Defines

#### HPX\_PP\_STRIP\_PARENS(X)

For any symbol *X*, this macro returns the same symbol from which potential outer parens have been removed. If no outer parens are found, this macros evaluates to *X* itself without error.

The original implementation of this macro is from Steven Watanbe as shown in <http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976>

```

HPX_PP_STRIP_PARENS(no_parens)
HPX_PP_STRIP_PARENS((with_parens))

```

#### Example Usage:

This produces the following output

```

no_parens
with_parens

```

#### Parameters

- **X** – Symbol to strip parens from

## hpx/preprocessor/nargs.hpp

Defined in header `hpx/preprocessor/nargs.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### Defines

#### HPX\_PP\_NARGS(...)

Expands to the number of arguments passed in

#### Example Usage:

```

HPX_PP_NARGS(hpx, pp, nargs)
HPX_PP_NARGS(hpx, pp)
HPX_PP_NARGS(hpx)

```

Expands to:

```
3
2
1
```

#### Parameters

- ... – The variadic number of arguments

### hpx/preprocessor/stringize.hpp

Defined in header `hpx/preprocessor/stringize.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

#### Defines

##### HPX\_PP\_STRINGIZE(X)

The `HPX_PP_STRINGIZE` macro stringizes its argument after it has been expanded.

The passed argument `X` will expand to `"X"`. Note that the stringizing operator (`#`) prevents arguments from expanding. This macro circumvents this shortcoming.

#### Parameters

- `X` – The text to be converted to a string literal

### hpx/preprocessor/cat.hpp

Defined in header `hpx/preprocessor/cat.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

#### Defines

##### HPX\_PP\_CAT(A, B)

Concatenates the tokens `A` and `B` into a single token. Evaluates to `AB`

#### Parameters

- `A` – First token
- `B` – Second token

## hpx/preprocessor/expand.hpp

Defined in header `hpx/preprocessor/expand.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### Defines

#### HPX\_PP\_EXPAND(X)

The `HPX_PP_EXPAND` macro performs a double macro-expansion on its argument.

This macro can be used to produce a delayed preprocessor expansion.

Example:

```
#define MACRO(a, b, c) (a)(b)(c)
#define ARGS() (1, 2, 3)

HPX_PP_EXPAND(MACRO ARGS()) // expands to (1)(2)(3)
```

#### Parameters

- **X** – Token to be expanded twice

## resiliency

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## hpx/resiliency/replicate\_executor.hpp

Defined in header `hpx/resiliency/replicate_executor.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
template<typename BaseExecutor, typename Voter, typename Validator>
```

```
struct is_two_way_executor<hpx::resiliency::experimental::replicate_executor<BaseExecutor, Voter, Validator>> : public true_type
```

```
template<typename BaseExecutor, typename Voter, typename Validator>
```

```
struct is_bulk_two_way_executor<hpx::resiliency::experimental::replicate_executor<BaseExecutor, Voter, Validator>> : public true_type
```

```
namespace hpx
```

```
namespace execution
```

```
namespace experimental
```

```
template<typename BaseExecutor, typename Voter,
typename Validator> replicate_executor< BaseExecutor, Voter,
Validator > > : public true_type
```

```
template<typename BaseExecutor, typename Voter,
typename Validator> replicate_executor< BaseExecutor, Voter,
Validator > > : public true_type
```

namespace **resiliency**

namespace **experimental**

## Functions

```
template<typename Tag, typename BaseExecutor, typename Vote, typename Validate,
typename Property>
auto tag_invoke(Tag tag, replicate_executor<BaseExecutor, Vote, Validate> const &exec,
Property &&prop) -> decltype(replicate_executor<BaseExecutor, Vote,
Validate>(std::declval<Tag>())(std::declval<BaseExecutor>()),
std::declval<Property>()), std::declval<std::size_t>(), std::declval<Vote>(),
std::declval<Validate>()))
```

```
template<typename Tag, typename BaseExecutor, typename Vote, typename Validate>
auto tag_invoke(Tag tag, replicate_executor<BaseExecutor, Vote, Validate> const &exec) ->
decltype(std::declval<Tag>())(std::declval<BaseExecutor>())
```

```
template<executor_any BaseExecutor, typename Voter, typename Validate>

## runtime\_configuration

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/runtime\_configuration/component\_registry\_base.hpp

Defined in header `hpx/runtime_configuration/component_registry_base.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

struct **component\_registry\_base**

*#include <component\_registry\_base.hpp>* The `component_registry_base` has to be used as a base class for all component registries.

#### Public Functions

virtual `~component_registry_base()` = default

virtual bool **get\_component\_info**(*std::vector<std::string> &fillini*, *std::string const &filepath*,  
bool *is\_static* = false) = 0

Return the ini-information for all contained components.

##### Parameters

- **fillini** – [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.
- **filepath** – [in]
- **is\_static** – [in]

##### Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

virtual void **register\_component\_type**() = 0

Register the component type represented by this component.

### hpx/runtime\_configuration/plugin\_registry\_base.hpp

Defined in header `hpx/runtime_configuration/plugin_registry_base.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **plugins**

struct **plugin\_registry\_base**

*#include <plugin\_registry\_base.hpp>* The `plugin_registry_base` has to be used as a base class for all plugin registries.

## Public Functions

virtual `~plugin_registry_base()` = default

virtual bool `get_plugin_info`(*std::vector<std::string> &fillini*) = 0

Return the configuration information for any plugin implemented by this module

### Parameters

**fillini** – [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all plugins implemented in this module.

### Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

inline virtual void `init`(int\*, char\*\*\*, *util::runtime\_configuration&*)

## HPX\_REGISTER\_COMPONENT\_MODULE

Defined in header `hpx/components.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## Defines

**HPX\_REGISTER\_COMMANDLINE\_REGISTRY**(RegistryType, componentname)

The macro *HPX\_REGISTER\_COMMANDLINE\_REGISTRY* is used to register the given component factory with `Hpx.Plugin`. This macro has to be used for each of the components.

**HPX\_REGISTER\_COMMANDLINE\_REGISTRY\_DYNAMIC**(RegistryType, componentname)

**HPX\_REGISTER\_COMMANDLINE\_OPTIONS**()

The macro *HPX\_REGISTER\_COMMANDLINE\_OPTIONS* is used to define the required `Hpx.Plugin` entry point for the command line option registry. This macro has to be used in not more than one compilation unit of a component module.

**HPX\_REGISTER\_COMMANDLINE\_OPTIONS\_DYNAMIC**()

**HPX\_REGISTER\_COMPONENT\_FACTORY**(componentname)

This macro is used to register the given component factory with `Hpx.Plugin`. This macro has to be used for each of the component factories.

**HPX\_REGISTER\_COMPONENT\_MODULE**()

This macro is used to define the required `Hpx.Plugin` entry points. This macro has to be used in exactly one compilation unit of a component module. Ungated: a component may live in a shared library, in a statically linked build, or directly in the application executable.

**HPX\_REGISTER\_COMPONENT\_MODULE\_DYNAMIC**()

**HPX\_REGISTER\_COMPONENT\_REGISTRY**(RegistryType, componentname)

This macro is used to register the given component factory with `Hpx.Plugin`. This macro has to be used for each of the components.

**HPX\_REGISTER\_COMPONENT\_REGISTRY\_DYNAMIC**(RegistryType, componentname)

**HPX\_REGISTER\_REGISTRY\_MODULE()**

This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module. Ungated: see HPX\_REGISTER\_COMPONENT\_MODULE.

**HPX\_REGISTER\_REGISTRY\_MODULE\_DYNAMIC()****HPX\_REGISTER\_PLUGIN\_BASE\_REGISTRY(PluginType, name)**

This macro is used to register the given plugin factory with Hpx.Plugin. This macro has to be used for each of the plugins. Ungated, matching the component analog (HPX\_REGISTER\_COMPONENT\_REGISTRY).

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_MODULE()**

This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a plugin module. Ungated: a plugin may live in a shared library, in a statically linked build, or directly in the application executable.

**HPX\_REGISTER\_PLUGIN\_REGISTRY\_MODULE\_DYNAMIC()****HPX\_DECLARE\_FACTORY\_STATIC(name, base)****HPX\_DEFINE\_FACTORY\_STATIC(module, name, base)****HPX\_INIT\_REGISTRY\_MODULE\_STATIC(name, base)****HPX\_INIT\_REGISTRY\_FACTORY\_STATIC(name, componentname, base)****HPX\_INIT\_REGISTRY\_COMMANDLINE\_STATIC(name, base)****HPX\_INIT\_REGISTRY\_STARTUP\_SHUTDOWN\_STATIC(name, base)****HPX\_INIT\_REGISTRY\_PLUGIN\_MODULE\_STATIC(name, base)****HPX\_INIT\_REGISTRY\_PLUGIN\_FACTORY\_STATIC(name, pluginname, base)****hpx::components::component\_commandline\_base**

Defined in header `hpx/components.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

struct **component\_commandline\_base**

*#include <component\_commandline\_base.hpp>* The `component_commandline_base` has to be used as a base class for all component command-line line handling registries.

## Public Functions

virtual `~component_commandline_base()` = default

virtual `hpx::program_options::options_description add_commandline_options()` = 0

Return any additional command line options valid for this component.

---

**Note:** This function will be executed by the runtime system during system startup.

---

### Returns

The module is expected to fill a `options_description` object with any additional command line options this component will handle.

## `hpx::runtime_mode`

Defined in header `hpx/init.hpp`<sup>748</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Enums

enum class **runtime\_mode** : `std::int8_t`

A HPX runtime can be executed in two different modes: console mode and worker mode.

*Values:*

enumerator **invalid**

enumerator **console**

The runtime is the console locality.

enumerator **worker**

The runtime is a worker locality.

enumerator **connect**

The runtime is a worker locality connecting late

enumerator **local**

The runtime is fully local.

enumerator **default\_**

The runtime mode will be determined based on the command line arguments

enumerator **last**

---

<sup>748</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init\\_runtime/include/hpx/init.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init_runtime/include/hpx/init.hpp)

## Functions

char const \***get\_runtime\_mode\_name**(runtime\_mode state) noexcept

Get the readable string representing the name of the given runtime\_mode constant.

runtime\_mode **get\_runtime\_mode\_from\_name**(std::string const &mode)

Returns the internal representation (runtime\_mode constant) from the readable string representing the name.

This represents the internal representation from the readable string representing the name.

### Parameters

**mode** – this represents the runtime mode

## runtime\_local

See *Public API* for a list of names and headers that are part of the public HPX API.

## hpx/runtime\_local/custom\_exception\_info.hpp

Defined in header hpx/runtime\_local/custom\_exception\_info.hpp.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

std::string **diagnostic\_information**(exception\_info const &xi)

Extract the diagnostic information embedded in the given exception and return a string holding a formatted message.

The function *hpx::diagnostic\_information* can be used to extract all diagnostic information stored in the given exception instance as a formatted string. This simplifies debug output as it composes the diagnostics into one, easy to use function call. This includes the name of the source file and line number, the sequence number of the OS-thread and the HPX-thread id, the locality id and the stack backtrace of the point where the original exception was thrown.

### See also:

*hpx::get\_error\_locality\_id()*, *hpx::get\_error\_host\_name()*, *hpx::get\_error\_process\_id()*,  
*hpx::get\_error\_function\_name()*, *hpx::get\_error\_file\_name()*, *hpx::get\_error\_line\_number()*,  
*hpx::get\_error\_os\_thread()*, *hpx::get\_error\_thread\_id()*, *hpx::get\_error\_thread\_description()*,  
*hpx::get\_error()*, *hpx::get\_error\_backtrace()*, *hpx::get\_error\_env()*, *hpx::get\_error\_what()*,  
*hpx::get\_error\_config()*, *hpx::get\_error\_state()*

### Parameters

**xi** – The parameter *e* will be inspected for all diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception\_info*, *hpx::error\_code*, *std::exception*, or *std::exception\_ptr*.

### Throws

*std::bad\_alloc* – (if any of the required allocation operations fail)

**Returns**

The formatted string holding all the available diagnostic information stored in the given exception instance.

`std::string default_diagnostic_information(std::exception_ptr const &e)`

`std::uint32_t get_error_locality_id(hpx::exception_info const &xi) noexcept`

Return the locality id where the exception was thrown.

The function `hpx::get_error_locality_id` can be used to extract the diagnostic information element representing the locality id as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`,  
`hpx::get_error()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`,  
`hpx::get_error_config()`, `hpx::get_error_state()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

nothing –

**Returns**

The locality id of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return `hpx::naming::invalid_locality_id`.

`std::string get_error_host_name(hpx::exception_info const &xi)`

Return the hostname of the locality where the exception was thrown.

The function `hpx::get_error_host_name` can be used to extract the diagnostic information element representing the host name as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_process_id()`, `hpx::get_error_function_name()`,  
`hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`,  
`hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error()`,  
`hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

`std::bad_alloc` – (if one of the required allocations fails)

**Returns**

The hostname of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::int64_t get_error_process_id(hpx::exception_info const &xi) noexcept`

Return the (operating system) process id of the locality where the exception was thrown.

The function `hpx::get_error_process_id` can be used to extract the diagnostic information element representing the process id as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_function_name()`,  
`hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`,  
`hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error()`,  
`hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

nothing –

**Returns**

The process id of the OS-process which threw the exception. If the exception instance does not hold this information, the function will return 0.

`std::string get_error_env(hpx::exception_info const &xi)`

Return the environment of the OS-process at the point the exception was thrown.

The function `hpx::get_error_env` can be used to extract the diagnostic information element representing the environment of the OS-process collected at the point the exception was thrown.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`,  
`hpx::get_error()`, `hpx::get_error_backtrace()`, `hpx::get_error_what()`, `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

`std::bad_alloc` – (if one of the required allocations fails)

**Returns**

The environment from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::string get_error_backtrace(hpx::exception_info const &xi)`

Return the stack backtrace from the point the exception was thrown.

The function `hpx::get_error_backtrace` can be used to extract the diagnostic information element representing the stack backtrace collected at the point the exception was thrown.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`,  
`hpx::get_error()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

`std::bad_alloc` – (if one of the required allocations fails)

**Returns**

The stack back trace from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::size_t get_error_os_thread(hpx::exception_info const &xi) noexcept`

Return the sequence number of the OS-thread used to execute HPX-threads from which the exception was thrown.

The function `hpx::get_error_os_thread` can be used to extract the diagnostic information element representing the sequence number of the OS-thread as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error()`,  
`hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

nothing –

**Returns**

The sequence number of the OS-thread used to execute the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return `std::size(-1)`.

`std::size_t` **get\_error\_thread\_id**(*hpx::exception\_info* const &xi) noexcept

Return the unique thread id of the HPX-thread from which the exception was thrown.

The function `hpx::get_error_thread_id` can be used to extract the diagnostic information element representing the HPX-thread id as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`, `hpx::get_error_thread_description()`, `hpx::get_error()`,  
`hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`,  
`hpx::get_error_state()`

**Parameters**

**xi** – The parameter *e* will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

nothing –

**Returns**

The unique thread id of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return `std::size_t(0)`.

`std::string` **get\_error\_thread\_description**(*hpx::exception\_info* const &xi)

Return any additionally available thread description of the HPX-thread from which the exception was thrown.

The function `hpx::get_error_thread_description` can be used to extract the diagnostic information element representing the additional thread description as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_backtrace()`,  
`hpx::get_error_env()`, `hpx::get_error()`, `hpx::get_error_state()`, `hpx::get_error_what()`,  
`hpx::get_error_config()`

**Parameters**

**xi** – The parameter *e* will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

`std::bad_alloc` – (if one of the required allocations fails)

**Returns**

Any additionally available thread description of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::string get_error_config(hpx::exception_info const &xi)`

Return the HPX configuration information point from which the exception was thrown.

The function `hpx::get_error_config` can be used to extract the HPX configuration information element representing the full HPX configuration information as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_backtrace()`,  
`hpx::get_error_env()`, `hpx::get_error()`, `hpx::get_error_state()` `hpx::get_error_what()`,  
`hpx::get_error_thread_description()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

`std::bad_alloc` – (if one of the required allocations fails)

**Returns**

Any additionally available HPX configuration information the point from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

`std::string get_error_state(hpx::exception_info const &xi)`

Return the HPX runtime state information at which the exception was thrown.

The function `hpx::get_error_state` can be used to extract the HPX runtime state information element representing the state the runtime system is currently in as stored in the given exception instance.

**See also:**

`hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`,  
`hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`,  
`hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_backtrace()`,  
`hpx::get_error_env()`, `hpx::get_error()`, `hpx::get_error_what()`, `hpx::get_error_thread_description()`

**Parameters**

**xi** – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Throws**

`std::bad_alloc` – (if one of the required allocations fails)

**Returns**

The point runtime state at the point at which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

**hpx::get\_initial\_num\_localities, hpx::get\_num\_localities**

Defined in header [hpx/runtime.hpp](#)<sup>749</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

`std::uint32_t get_initial_num_localities()`

Return the number of localities which were registered at startup for the running application.

The function `get_initial_num_localities` returns the number of localities which were connected to the console at application startup.

**See also:**

`hpx::find_all_localities`, `hpx::get_num_localities`

---

**Note:** As long as *ec* is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of `hpx::exception`.

---

`hpx::future<std::uint32_t> get_num_localities()`

Asynchronously return the number of localities which are currently registered for the running application.

The function `get_num_localities` asynchronously returns the number of localities currently connected to the console. The returned future represents the actual result.

**See also:**

`hpx::find_all_localities`, `hpx::get_num_localities`

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

---

`std::uint32_t get_num_localities(launch::sync_policy, error_code &ec = throws)`

Return the number of localities which are currently registered for the running application.

The function `get_num_localities` returns the number of localities currently connected to the console.

**See also:**

`hpx::find_all_localities`, `hpx::get_num_localities`

---

<sup>749</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

---

**Note:** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

**ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

### **hpx::startup\_function\_type, hpx::register\_pre\_startup\_function, hpx::register\_startup\_function**

Defined in header [hpx/runtime.hpp](#)<sup>750</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

#### Typedefs

using **startup\_function\_type** = *hpx::move\_only\_function*<void()>

The type of the function which is registered to be executed as a startup or pre-startup function.

#### Functions

void **register\_pre\_startup\_function**(*startup\_function\_type* f)

Add a function to be executed by a HPX thread before *hpx\_main* but guaranteed before any startup function is executed (system-wide).

Any of the functions registered with *register\_pre\_startup\_function* are guaranteed to be executed by an HPX thread before any of the registered startup functions are executed (see *hpx::register\_startup\_function()*).

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

#### See also:

*hpx::register\_startup\_function()*

---

**Note:** If this function is called while the pre-startup functions are being executed or after that point, it will raise *aninvalid\_status* exception.

---

---

<sup>750</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

**Parameters**

**f** – [in] The function to be registered to run by an HPX thread as a pre-startup function.

void **register\_startup\_function**(*startup\_function\_type* f)

Add a function to be executed by a HPX thread before `hpx_main` but guaranteed after any pre-startup function is executed (system-wide).

Any of the functions registered with `register_startup_function` are guaranteed to be executed by an HPX thread after any of the registered pre-startup functions are executed (see: `hpx::register_pre_startup_function()`), but before `hpx_main` is being called.

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

**See also:**

`hpx::register_pre_startup_function()`

---

**Note:** If this function is called while the startup functions are being executed or after that point, it will raise an `invalid_status` exception.

---

**Parameters**

**f** – [in] The function to be registered to run by an HPX thread as a startup function.

**hpx::get\_locality\_name**

Defined in header `hpx/runtime.hpp`<sup>751</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

*std::string* **get\_locality\_name**()

Return the name of the locality this function is called on.

This function returns the name for the locality on which this function is called.

**See also:**

*future<std::string>* `get_locality_name(hpx::id_type const& id)`

**Returns**

This function returns the name for the locality on which the function is called. The name is retrieved from the underlying networking layer and may be different for different parcelports.

---

<sup>751</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

### hpx/runtime\_local/get\_worker\_thread\_num.hpp

Defined in header `hpx/runtime_local/get_worker_thread_num.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/runtime\_local/get\_os\_thread\_count.hpp

Defined in header `hpx/runtime_local/get_os_thread_count.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

#### Functions

`std::size_t get_os_thread_count()`

Return the number of OS-threads running in the runtime instance the current HPX-thread is associated with.

`std::size_t get_os_thread_count(threads::executor const &exec)`

Return the number of worker OS- threads used by the given executor to execute HPX threads.

This function returns the number of cores used to execute HPX threads for the given executor. If the function is called while no HPX runtime system is active, it will return zero. If the executor is not valid, this function will fall back to retrieving the number of OS threads used by HPX.

#### Parameters

**exec** – [in] The executor to be used.

namespace **threads**

### hpx/runtime\_local/thread\_pool\_helpers.hpp

Defined in header `hpx/runtime_local/thread_pool_helpers.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resource**

## Functions

`std::size_t get_num_thread_pools()`

Return the number of thread pools currently managed by the *resource\_partitioner*

`std::size_t get_num_threads()`

Return the number of threads in all thread pools currently managed by the *resource\_partitioner*

`std::size_t get_num_threads(std::string const &pool_name)`

Return the number of threads in the given thread pool currently managed by the *resource\_partitioner*

`std::size_t get_num_threads(std::size_t pool_index)`

Return the number of threads in the given thread pool currently managed by the *resource\_partitioner*

`std::size_t get_pool_index(std::string const &pool_name)`

Return the internal index of the pool given its name.

`std::string const &get_pool_name(std::size_t pool_index)`

Return the name of the pool given its internal index.

`threads::thread_pool_base &get_thread_pool(std::string const &pool_name)`

Return the name of the pool given its name.

`threads::thread_pool_base &get_thread_pool(std::size_t pool_index)`

Return the thread pool given its internal index.

`bool pool_exists(std::string const &pool_name)`

Return true if the pool with the given name exists.

`bool pool_exists(std::size_t pool_index)`

Return true if the pool with the given index exists.

namespace **threads**

## Functions

`std::int64_t get_thread_count(thread_schedule_state state = thread_schedule_state::unknown)`

The function *get\_thread\_count* returns the number of currently known threads.

---

**Note:** If `state == unknown` this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

---

### Parameters

**state** – [in] This specifies the thread-state for which the number of threads should be retrieved.

`std::int64_t get_thread_count(thread_priority priority, thread_schedule_state state = thread_schedule_state::unknown)`

The function *get\_thread\_count* returns the number of currently known threads.

---

**Note:** If `state == unknown` this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

---

#### Parameters

- **priority** – [in] This specifies the thread-priority for which the number of threads should be retrieved.
- **state** – [in] This specifies the thread-state for which the number of threads should be retrieved.

`std::int64_t` **get\_idle\_core\_count()**

The function `get_idle_core_count` returns the number of currently idling threads (cores).

`mask_type` **get\_idle\_core\_mask()**

The function `get_idle_core_mask` returns a bit-mask representing the currently idling threads (cores).

`bool` **enumerate\_threads**(*hpx::function<bool(thread\_id\_type)> const &f, thread\_schedule\_state state = thread\_schedule\_state::unknown*)

The function `enumerate_threads` will invoke the given function *f* for each thread with a matching thread state.

#### Parameters

- **f** – [in] The function which should be called for each matching thread. Returning ‘false’ from this function will stop the enumeration process.
- **state** – [in] This specifies the thread-state for which the threads should be enumerated.

## hpx/runtime\_local/service\_executors.hpp

Defined in header `hpx/runtime_local/service_executors.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

## Enums

enum class **service\_executor\_type** : `std::uint8_t`

*Values:*

enumerator **io\_thread\_pool**

Selects creating a service executor using the I/O pool of threads

enumerator **parcel\_thread\_pool**

Selects creating a service executor using the parcel pool of threads

enumerator **timer\_thread\_pool**

Selects creating a service executor using the timer pool of threads

enumerator **main\_thread**

Selects creating a service executor using the main thread

struct **io\_pool\_executor** : public *hpx::execution::experimental::service\_executor*

### Public Functions

**io\_pool\_executor**()

struct **main\_pool\_executor** : public *hpx::execution::experimental::service\_executor*

### Public Functions

**main\_pool\_executor**()

struct **parcel\_pool\_executor** : public *hpx::execution::experimental::service\_executor*

### Public Functions

explicit **parcel\_pool\_executor**(char const \*name\_suffix = "-tcp")

struct **service\_executor** : public *service\_executor*

Subclassed by *hpx::execution::experimental::io\_pool\_executor*,  
*hpx::execution::experimental::main\_pool\_executor*, *hpx::execution::experimental::parcel\_pool\_executor*,  
*hpx::execution::experimental::timer\_pool\_executor*

### Public Functions

explicit **service\_executor**(*service\_executor\_type* t, char const \*name\_suffix = "")

struct **timer\_pool\_executor** : public *hpx::execution::experimental::service\_executor*

### Public Functions

**timer\_pool\_executor**()

**hpx::shutdown\_function\_type, hpx::register\_pre\_shutdown\_function, hpx::register\_shutdown\_function**

Defined in header [hpx/runtime.hpp](#)<sup>752</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Typedefs**

using **shutdown\_function\_type** = *hpx::move\_only\_function*<void()>

The type of the function which is registered to be executed as a shutdown or pre-shutdown function.

**Functions**

void **register\_pre\_shutdown\_function**(*shutdown\_function\_type* f)

Add a function to be executed by a HPX thread during *hpx::finalize()* but guaranteed before any shutdown function is executed (system-wide)

Any of the functions registered with *register\_pre\_shutdown\_function* are guaranteed to be executed by an HPX thread during the execution of *hpx::finalize()* before any of the registered shutdown functions are executed (see: *hpx::register\_shutdown\_function()*).

**See also:**

*hpx::register\_shutdown\_function()*

---

**Note:** If this function is called while the pre-shutdown functions are being executed, or after that point, it will raise an *invalid\_status* exception.

---

**Parameters**

**f** – [in] The function to be registered to run by an HPX thread as a pre-shutdown function.

void **register\_shutdown\_function**(*shutdown\_function\_type* f)

Add a function to be executed by a HPX thread during *hpx::finalize()* but guaranteed after any pre-shutdown function is executed (system-wide)

Any of the functions registered with *register\_shutdown\_function* are guaranteed to be executed by an HPX thread during the execution of *hpx::finalize()* after any of the registered pre-shutdown functions are executed (see: *hpx::register\_pre\_shutdown\_function()*).

**See also:**

*hpx::register\_pre\_shutdown\_function()*

---

**Note:** If this function is called while the shutdown functions are being executed, or after that point, it will raise an *invalid\_status* exception.

---

---

<sup>752</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

**Parameters**

**f** – [in] The function to be registered to run by an HPX thread as a shutdown function.

**hpx/runtime\_local/runtime\_local.hpp**

Defined in header `hpx/runtime_local/runtime_local.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

void **set\_error\_handlers**(*hpx::util::runtime\_configuration* const &cfg)

class **runtime**

**Public Types**

using **notification\_policy\_type** = *threads::policies::callback\_notifier*

Generate a new notification policy instance for the given thread name prefix

using **hpx\_main\_function\_type** = int()

The *hpx\_main\_function\_type* is the default function type usable as the main HPX thread function.

using **hpx\_errorsink\_function\_type** = void(*std::uint32\_t*, *std::string* const&)

**Public Functions**

virtual *notification\_policy\_type* **get\_notification\_policy**(char const \*prefix,  
runtime\_local::os\_thread\_type type)

state **get\_state**() const

void **set\_state**(state s)

explicit **runtime**(*hpx::util::runtime\_configuration* rtcfg, bool initialize)

Construct a new HPX runtime instance.

virtual **~runtime**()

The destructor makes sure all HPX runtime services are properly shut down before exiting.

void **on\_exit**(*hpx::function<void()>* const &f)

Manage list of functions to call on exit.

void **starting**()

Manage runtime ‘stopped’ state.

void **stopping**()

Call all registered `on_exit` functions.

bool **stopped**() const

This accessor returns whether the runtime instance has been stopped.

*hpx::util::runtime\_configuration* &**get\_config**()

access configuration information

*hpx::util::runtime\_configuration* const &**get\_config**() const

*std::size\_t* **get\_instance\_number**() const

*util::thread\_mapper* &**get\_thread\_mapper**() const

Return a reference to the internal PAPI thread manager.

*threads::topology* const &**get\_topology**() const

virtual int **run**(*hpx::function<hpx\_main\_function\_type>* const &func)

Run the HPX runtime system, use the given function for the main *thread* and block waiting for all threads to finish.

---

**Note:** The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

---

#### Parameters

**func** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx\_main\_function\_type*. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

#### Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter **func**.

virtual int **run**()

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

#### Returns

This function will always return 0 (zero).

virtual void **rethrow\_exception**()

Rethrow any stored exception (to be called after *stop()*)

virtual int **start**(*hpx::function<hpx\_main\_function\_type>* const &func, bool blocking = false)

Start the runtime system.

#### Parameters

- **func** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx\_main\_function\_type*.
- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally.

#### Returns

If a blocking is a true, this function will return the value as returned as the result of the

invocation of the function object given by the parameter `func`. Otherwise, it will return zero.

virtual int **start**(bool blocking = false)

Start the runtime system.

#### Parameters

**blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function `runtime::start` will call `runtime::wait` internally .

#### Returns

If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise, it will return zero.

virtual int **wait**()

Wait for the shutdown action to be executed.

#### Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

virtual void **stop**(bool blocking = true)

Initiate termination of the runtime system.

#### Parameters

**blocking** – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

virtual int **suspend**()

Suspend the runtime system.

virtual int **resume**()

Resume the runtime system.

virtual int **finalize**(double)

virtual bool **is\_networking\_enabled**()

Return true if networking is enabled.

virtual *hpx::threads::threadmanager* &**get\_thread\_manager**()

Allow access to the thread manager instance used by the HPX runtime.

virtual *std::string* **here**() const

Returns a string of the locality endpoints (usable in debug output)

virtual bool **report\_error**(*std::size\_t* num\_thread, *std::exception\_ptr* const &e, bool terminate\_all = true)

Report a non-recoverable error to the runtime system.

#### Parameters

- **num\_thread** – [in] The number of the operating system thread the error has been detected in.
- **e** – [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate\_all** – [in] signal whether all localities should be terminated

virtual bool **report\_error**(*std::exception\_ptr* const &e, bool terminate\_all = true)

Report a non-recoverable error to the runtime system.

---

**Note:** This function will retrieve the number of the current shepherd thread and forward to the `report_error` function above.

---

**Parameters**

- **e** – [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate\_all** – [in] signal whether all localities should be terminated

virtual void **add\_pre\_startup\_function**(*startup\_function\_type* f)

Add a function to be executed inside a HPX thread before `hpx_main` but guaranteed to be executed before any startup function registered with `add_startup_function`.

---

**Note:** The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

---

**Parameters**

**f** – The function ‘f’ will be called from inside a HPX thread before `hpx_main` is executed. This is very useful to set up the runtime environment of the application (install performance counters, etc.)

virtual void **add\_startup\_function**(*startup\_function\_type* f)

Add a function to be executed inside a HPX thread before `hpx_main`

**Parameters**

**f** – The function ‘f’ will be called from inside a HPX thread before `hpx_main` is executed. This is very useful to set up the runtime environment of the application (install performance counters, etc.)

virtual void **add\_pre\_shutdown\_function**(*shutdown\_function\_type* f)

Add a function to be executed inside a HPX thread during `hpx::finalize`, but guaranteed before any of the shutdown functions is executed.

---

**Note:** The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

---

**Parameters**

**f** – The function ‘f’ will be called from inside a HPX thread while `hpx::finalize` is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

virtual void **add\_shutdown\_function**(*shutdown\_function\_type* f)

Add a function to be executed inside a HPX thread during `hpx::finalize`

**Parameters**

**f** – The function ‘f’ will be called from inside a HPX thread while `hpx::finalize` is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

virtual *hpx::util::io\_service\_pool* \***get\_thread\_pool**(char const \*name)

Access one of the internal thread pools (`io_service` instances) HPX is using to perform specific tasks. The three possible values for the argument `name` are “main\_pool”, “io\_pool”, “parcel\_pool”, and “timer\_pool”. For any other argument value the function will return zero.

virtual bool **register\_thread**(char const \*name, *std::size\_t* num = 0, bool service\_thread = true, *error\_code* &ec = throws)

Register an external OS-thread with HPX.

This function should be called from any OS-thread which is external to HPX (not created by HPX), but which needs to access HPX functionality, such as setting a value on a promise or similar.

‘main’, ‘io’, ‘timer’, ‘parcel’, ‘worker’

---

**Note:** The function will compose a thread name of the form ‘<name>-thread#<num>’ which is used to register the thread. It is the user’s responsibility to ensure that each (composed) thread name is unique. HPX internally uses the following names for the threads it creates, do not reuse those:

---

---

**Note:** This function should be called for each thread exactly once. It will fail if it is called more than once.

---

#### Parameters

- **name** – [in] The name to use for thread registration.
- **num** – [in] The sequence number to use for thread registration. The default for this parameter is zero.
- **service\_thread** – [in] The thread should be registered as a service thread. The default for this parameter is ‘true’. Any service threads will be pinned to cores not currently used by any of the HPX worker threads.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function will return whether the requested operation succeeded or not.

virtual bool **unregister\_thread()**

Unregister an external OS-thread with HPX.

This function will unregister any external OS-thread from HPX.

---

**Note:** This function should be called for each thread exactly once. It will fail if it is called more than once. It will fail as well if the thread has not been registered before (see *register\_thread*).

---

#### Returns

This function will return whether the requested operation succeeded or not.

virtual runtime\_local::os\_thread\_data **get\_os\_thread\_data**(std::string const &label) const

Access data for a given OS thread that was previously registered by *register\_thread*.

virtual bool **enumerate\_os\_threads**(hpx::function<bool(runtime\_local::os\_thread\_data const&)> const &f) const

Enumerate all OS threads that have registered with the runtime.

notification\_policy\_type::on\_startstop\_type **on\_start\_func**() const

notification\_policy\_type::on\_startstop\_type **on\_stop\_func**() const

notification\_policy\_type::on\_error\_type **on\_error\_func**() const

## Private Functions

void **stop\_helper**(bool blocking, `std::condition_variable &cond`, `std::mutex &mtx`) const

Helper function to stop the runtime.

### Parameters

- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.
- **cond** –
- **mtx** –

namespace **threads**

## Functions

char const \***get\_stack\_size\_name**(std::ptrdiff\_t size)

Returns the stack size name.

Get the readable string representing the given stack size constant.

### Parameters

**size** – this represents the stack size

std::ptrdiff\_t **get\_default\_stack\_size**()

Returns the default stack size.

Get the default stack size in bytes.

std::ptrdiff\_t **get\_stack\_size**(thread\_stacksize size)

Returns the stack size corresponding to the given stack size enumeration.

Get the stack size corresponding to the given stack size enumeration.

### Parameters

**size** – this represents the stack size

namespace **util**

## Functions

bool **retrieve\_commandline\_arguments**(hpx::program\_options::options\_description const  
&app\_options, hpx::program\_options::variables\_map  
&vm)

bool **retrieve\_commandline\_arguments**(std::string const &app\_name,  
hpx::program\_options::variables\_map &vm)

## hpx/runtime\_local/thread\_hooks.hpp

Defined in header `hpx/runtime_local/thread_hooks.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

## Functions

*threads::policies::callback\_notifier::on\_startstop\_type* **get\_thread\_on\_start\_func()**

Retrieve the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *register\_thread\_on\_start\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

### Returns

The currently installed error handler function.

*threads::policies::callback\_notifier::on\_startstop\_type* **get\_thread\_on\_stop\_func()**

Retrieve the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see *register\_thread\_on\_stop\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

### Returns

The currently installed error handler function.

*threads::policies::callback\_notifier::on\_error\_type* **get\_thread\_on\_error\_func()**

Retrieve the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see *register\_thread\_on\_error\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

### Returns

The currently installed error handler function.

*threads::policies::callback\_notifier::on\_startstop\_type* **register\_thread\_on\_start\_func**(*threads::policies::callback\_notifier::*  
*&&f*)

Set the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *get\_thread\_on\_start\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

### Parameters

**f** – The function to install as the new start handler.

**Returns**

The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

*threads::policies::callback\_notifier::on\_startstop\_type* **register\_thread\_on\_stop\_func**(*threads::policies::callback\_notifier::on\_startstop\_type* &&f)

Set the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see *get\_thread\_on\_stop\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Parameters**

**f** – The function to install as the new stop handler.

**Returns**

The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

*threads::policies::callback\_notifier::on\_error\_type* **register\_thread\_on\_error\_func**(*threads::policies::callback\_notifier::on\_error\_type* &&f)

Set the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see *get\_thread\_on\_error\_func*).

---

**Note:** This function can be called before the HPX runtime is initialized.

---

**Parameters**

**f** – The function to install as the new error handler.

**Returns**

The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

## hpx/runtime\_local/report\_error.hpp

Defined in header `hpx/runtime_local/report_error.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

## Functions

void **report\_error**(*std::size\_t* num\_thread, *std::exception\_ptr* const &e)

The function `report_error` reports the given exception to the console.

void **report\_error**(*std::exception\_ptr* const &e)

The function `report_error` reports the given exception to the console.

## `hpx::get_locality_id`

Defined in header `hpx/runtime.hpp`<sup>753</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

## Functions

*std::uint32\_t* **get\_locality\_id**(*error\_code* &ec = *throws*)

Return the number of the locality this function is being called from.

This function returns the id of the current locality.

---

**Note:** The returned value is zero based and its maximum value is smaller than the overall number of localities the current application is running on (as returned by `get_num_localities()`).

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

## Parameters

**ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

## `hpx/runtime_local/termination_detection.hpp`

Defined in header `hpx/runtime_local/termination_detection.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **local**

---

<sup>753</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

## Functions

void **termination\_detection()**

Wait for all local HPX threads to complete execution.

This function blocks the calling thread until all HPX worker threads on the current locality have completed their work and become idle. It performs local termination detection by waiting for the thread manager to drain all pending tasks.

**Example:**

```
#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>

int hpx_main()
{
    // Launch some asynchronous work
    for (int i = 0; i < 100; ++i)
    {
        hpx::post([]{ /* do work */ });
    }

    // Wait for all local threads to complete
    hpx::local::termination_detection();

    return hpx::finalize();
}
```

**Note:** This function should be called from an HPX thread or after the HPX runtime has been initialized.

### Throws

*hpx::exception* – if called when the runtime is not in a valid state (e.g., before initialization or after shutdown).

bool **termination\_detection**(*hpx::chrono::steady\_duration* const &timeout)

Wait for all local HPX threads to complete with a timeout.

This function blocks the calling thread until either all HPX worker threads have completed their work, or the specified timeout duration has elapsed.

**See also:**

termination\_detection()

**Example:**

```
#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>
#include <chrono>

int hpx_main()
{
```

(continues on next page)

(continued from previous page)

```

// Launch some work
hpx::post([]{ /* long running task */ });

// Wait up to 5 seconds
if (!hpx::local::termination_detection(std::chrono::seconds(5)))
{
    std::cerr << "Warning: Work did not complete within timeout\n";
    // Implement fallback strategy
}

return hpx::finalize();
}

```

**Parameters**

**timeout** – Maximum duration to wait for termination. The function will return false if this duration elapses before all threads complete.

**Throws**

*hpx::exception* – if called when the runtime is not in a valid state.

**Returns**

true if all threads completed before the timeout, false if the timeout elapsed.

bool **termination\_detection**(*hpx::chrono::steady\_time\_point* const &deadline)

Wait for all local HPX threads to complete until a deadline.

This function blocks the calling thread until either all HPX worker threads have completed their work, or the specified deadline time point is reached.

**See also:**

`termination_detection(std::chrono::duration<double>)`

**Example:**

```

#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>
#include <chrono>

int hpx_main()
{
    auto deadline = std::chrono::steady_clock::now() +
        std::chrono::seconds(10);

    hpx::post([]{ /* work */ });

    if (!hpx::local::termination_detection(deadline))
    {
        std::cerr << "Deadline reached\n";
    }

    return hpx::finalize();
}

```

**Parameters**

**deadline** – Absolute time point when waiting should stop. The function will return false

if this time is reached before all threads complete.

**Throws**

`hpx::exception` – if called when the runtime is not in a valid state.

**Returns**

true if all threads completed before the deadline, false if the deadline was reached.

```
bool termination_detection(hpx::stop_token stop_token, hpx::chrono::steady_duration const
    &timeout =
    hpx::chrono::steady_duration((hpx::chrono::steady_clock::duration::max)()))
```

Wait for all local HPX threads with cancellation support.

This function blocks the calling thread until all HPX worker threads have completed, the timeout elapses, or a stop is requested via the `stop_token`. This enables cooperative cancellation of the wait operation.

**See also:**

`termination_detection(std::chrono::duration<double>)`

**Example:**

```
#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>
#include <hpx/stop_token.hpp>
#include <chrono>

int hpx_main()
{
    hpx::stop_source stop_src;

    // In shutdown handler
    hpx::thread shutdown_thread([&stop_src]() {
        hpx::this_thread::sleep_for(std::chrono::seconds(30));
        stop_src.request_stop();
    });

    hpx::post([]{ /* work */ });

    // Wait with cancellation support
    bool completed = hpx::local::termination_detection(
        stop_src.get_token(),
        std::chrono::minutes(1)
    );

    if (!completed)
    {
        std::cerr << "Cancelled or timed out\n";
    }

    shutdown_thread.join();
    return hpx::finalize();
}
```

**Parameters**

- **stop\_token** – Token that can be used to request cancellation of the wait operation.

- **timeout** – Maximum duration to wait. Defaults to maximum duration (effectively infinite).

**Throws**

*hpx::exception* – if called when the runtime is not in a valid state.

**Returns**

true if all threads completed, false if timeout elapsed or stop was requested.

**hpx::get\_thread\_name**

Defined in header [hpx/runtime.hpp](#)<sup>754</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

*std::string* **get\_thread\_name**()

Return the name of the calling thread.

This function returns the name of the calling thread. This name uniquely identifies the thread in the context of HPX. If the function is called while no HPX runtime system is active, the result will be “<unknown>”.

**hpx::register\_thread**, **hpx::unregister\_thread**, **hpx::get\_os\_thread\_data**,  
**hpx::enumerate\_os\_threads**, **hpx::get\_runtime\_instance\_number**, **hpx::register\_on\_exit**,  
**hpx::is\_starting**, **hpx::tolerate\_node\_faults**, **hpx::is\_running**, **hpx::is\_stopped**,  
**hpx::is\_stopped\_or\_shutting\_down**, **hpx::get\_num\_worker\_threads**, **hpx::get\_system\_uptime**

Defined in header [hpx/runtime.hpp](#)<sup>755</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

bool **register\_thread**(*runtime* \*rt, char const \*name, *error\_code* &ec = throws)

Register the current kernel thread with HPX, this should be done once for each external OS-thread intended to invoke HPX functionality. Calling this function more than once will return false.

void **unregister\_thread**(*runtime* \*rt)

Unregister the thread from HPX, this should be done once in the end before the external thread exists.

*runtime\_local::os\_thread\_data* **get\_os\_thread\_data**(*std::string* const &label)

Access data for a given OS thread that was previously registered by *register\_thread*. This function must be called from a thread that was previously registered with the runtime.

bool **enumerate\_os\_threads**(*hpx::function*<bool(*os\_thread\_data* const&)> const &f)

Enumerate all OS threads that have registered with the runtime.

---

<sup>754</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

<sup>755</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

`std::size_t get_runtime_instance_number()`

Return the runtime instance number associated with the runtime instance the current thread is running in.

bool **register\_on\_exit**(*hpx::function<void()> const&*)

Register a function to be called during system shutdown.

bool **is\_starting**()

Test whether the runtime system is currently being started.

This function returns whether the runtime system is currently being started or not, e.g. whether the current state of the runtime system is *hpx::state::startup*

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

bool **tolerate\_node\_faults**()

Test if HPX runs in fault-tolerant mode.

This function returns whether the runtime system is running in fault-tolerant mode

bool **is\_running**()

Test whether the runtime system is currently running.

This function returns whether the runtime system is currently running or not, e.g. whether the current state of the runtime system is *hpx::state::running*

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

bool **is\_stopped**()

Test whether the runtime system is currently stopped.

This function returns whether the runtime system is currently stopped or not, e.g. whether the current state of the runtime system is *hpx::state::stopped*

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

bool **is\_stopped\_or\_shutting\_down**()

Test whether the runtime system is currently being shut down.

This function returns whether the runtime system is currently being shut down or not, e.g. whether the current state of the runtime system is *hpx::state::stopped* or *hpx::state::shutdown*

---

**Note:** This function needs to be executed on a HPX-thread. It will return false otherwise.

---

`std::size_t get_num_worker_threads()`

Return the number of worker OS- threads used to execute HPX threads.

This function returns the number of OS-threads used to execute HPX threads. If the function is called while no HPX runtime system is active, it will return zero.

`std::uint64_t get_system_uptime()`

Return the system uptime measure on the thread executing this call.

This function returns the system uptime measured in nanoseconds for the thread executing this call. If the function is called while no HPX runtime system is active, it will return zero.

namespace **threads**

## hpx/runtime\_local/component\_startup\_shutdown\_base.hpp

Defined in header `hpx/runtime_local/component_startup_shutdown_base.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

struct **component\_startup\_shutdown\_base**

*#include <component\_startup\_shutdown\_base.hpp>* The `component_startup_shutdown_base` has to be used as a base class for all component startup/shutdown registries.

### Public Functions

virtual `~component_startup_shutdown_base()` = default

virtual bool **get\_startup\_function**(*startup\_function\_type* &startup, bool &pre\_startup) = 0

Return any startup function for this component.

#### Parameters

- **startup** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.
- **pre\_startup** – [in, out] Will be set to true if the returned startup function is executed during the first round of calls.

#### Returns

Returns *true* if the parameter *startup* has been successfully initialized with the startup function.

virtual bool **get\_shutdown\_function**(*shutdown\_function\_type* &shutdown, bool &pre\_shutdown) = 0

Return any startup function for this component.

#### Parameters

- **shutdown** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.
- **pre\_shutdown** – [in, out] Will be set to true if the returned shutdown function is executed during the first round of calls.

#### Returns

Returns *true* if the parameter *shutdown* has been successfully initialized with the shutdown function.

## serialization

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/serialization/base\_object.hpp

Defined in header `hpx/serialization/base_object.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## synchronization

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/synchronization/event.hpp

Defined in header `hpx/synchronization/event.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace lcos
```

namespace **local**

class **event**

*#include <event.hpp>* Event semaphores can be used for synchronizing multiple threads that need to wait for an event to occur. When the event occurs, all threads waiting for the event are woken up.

### Public Functions

inline **event**() noexcept

Construct a new event semaphore.

inline bool **occurred**() const noexcept

Check if the event has occurred.

inline void **wait**()

Wait for the event to occur.

inline void **set**()

Release all threads waiting on this semaphore.

inline void **reset**() noexcept

Reset the event.

### Private Types

using **mutex\_type** = *hpx::spinlock*

### Private Functions

inline void **wait\_locked**(*std::unique\_lock<mutex\_type> &l*)

inline void **set\_locked**(*std::unique\_lock<mutex\_type> l*)

### Private Members

*std::atomic<bool>* **event\_**

## hpx::no\_mutex

Defined in header [hpx/mutex.hpp](#)<sup>756</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

struct **no\_mutex**

*#include <no\_mutex.hpp>* **no\_mutex** class can be used in cases where the shared data between multiple threads can be accessed simultaneously without causing inconsistencies.

### Public Static Functions

static inline constexpr void **lock**() noexcept

static inline constexpr bool **try\_lock**() noexcept

static inline constexpr void **unlock**() noexcept

## hpx::binary\_semaphore

Defined in header [hpx/semaphore.hpp](#)<sup>757</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

class **binary\_semaphore**

*#include <binary\_semaphore.hpp>* A binary semaphore is a semaphore object that has only two states. **binary\_semaphore** is an alias for specialization of **hpx::counting\_semaphore** with *LeastMaxValue* being 1. HPX's implementation of **binary\_semaphore** is more efficient than the default implementation of a counting semaphore with a unit resource count (**hpx::counting\_semaphore**).

### Public Functions

**binary\_semaphore**(*binary\_semaphore* const&) = delete

*binary\_semaphore* &**operator**=(*binary\_semaphore* const&) = delete

**binary\_semaphore**(*binary\_semaphore*&&) = delete

*binary\_semaphore* &**operator**=(*binary\_semaphore*&&) = delete

explicit **binary\_semaphore**(std::ptrdiff\_t value = 1)

Constructs an object of type **hpx::binary\_semaphore** with the internal counter initialized to *value*.

---

<sup>756</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/mutex.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/mutex.hpp)

<sup>757</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/semaphore.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/semaphore.hpp)

**Parameters**

**value** – The initial value of the internal semaphore lock count. Normally this value should be zero (which is the default), values greater than zero are equivalent to the same number of signals pre-set, and negative values are equivalent to the same number of waits pre-set.

**~binary\_semaphore()** = default

void **release**(std::ptrdiff\_t update = 1)

Atomically increments the internal counter by the value of update. Any thread(s) waiting for the counter to be greater than 0, such as due to being blocked in acquire, will subsequently be unblocked.

---

**Note:** Synchronization: Strongly happens before invocations of *try\_acquire* that observe the result of the effects.

---

**Throws**

std::system\_error –

**Parameters**

**update** – the amount to increment the internal counter by

**Pre**

Both `update >= 0` and `update <= max() - counter` are *true*, where *counter* is the value of the internal counter.

bool **try\_acquire**() noexcept

Tries to atomically decrement the internal counter by 1 if it is greater than 0; no blocking occurs regardless.

**Returns**

*true* if it decremented the internal counter, otherwise *false*

void **acquire**()

Repeatedly performs the following steps, in order:

- Evaluates *try\_acquire*. If the result is true, returns.
- Blocks on *\*this* until counter is greater than zero.

**Throws**

std::system\_error –

**Returns**

*void*.

bool **try\_acquire\_until**(hpx::chrono::steady\_time\_point const &abs\_time)

Tries to atomically decrement the internal counter by 1 if it is greater than 0; otherwise blocks until it is greater than 0 and can successfully decrement the internal counter, or the *abs\_time* time point has been passed.

**Parameters**

**abs\_time** – the earliest time the function must wait until in order to fail

**Throws**

std::system\_error –

**Returns**

*true* if it decremented the internal counter, otherwise *false*.

bool **try\_acquire\_for**(hpx::chrono::steady\_duration const &rel\_time)

Tries to atomically decrement the internal counter by 1 if it is greater than 0; otherwise blocks until it is greater than 0 and can successfully decrement the internal counter, or the *rel\_time* duration has been exceeded.

**Throws**

`std::system_error` –

**Parameters**

**rel\_time** – the minimum duration the function must wait for to fail

**Returns**

*true* if it decremented the internal counter, otherwise *false*

**Public Static Functions**

static constexpr `std::ptrdiff_t` **max()** noexcept

Returns The maximum value of counter. This value is greater than or equal to *LeastMaxValue*.

**Returns**

The internal counter's maximum possible value, as a `std::ptrdiff_t`.

**hpx::condition\_variable, hpx::condition\_variable\_any, hpx::cv\_status**

Defined in header `hpx/condition_variable.hpp`<sup>758</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Enums**

enum class **cv\_status**

The scoped enumeration `hpx::cv_status` describes whether a timed wait returned because of timeout or not. `hpx::cv_status` is used by the `wait_for` and `wait_until` member functions of `hpx::condition_variable` and `hpx::condition_variable_any`.

*Values:*

enumerator **no\_timeout**

The condition variable was awakened with *notify\_all*, *notify\_one*, or spuriously

enumerator **timeout**

the condition variable was awakened by timeout expiration

enumerator **error**

there was an error

class **condition\_variable**

`#include <condition_variable.hpp>` The `condition_variable` class is a synchronization primitive that can be used to block a thread, or multiple threads at the same time, until another thread both modifies a shared variable (the condition), and notifies the `condition_variable`.

The thread that intends to modify the shared variable has to

- i. acquire a `hpx::mutex` (typically via `std::lock_guard`)

---

<sup>758</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/condition\\_variable.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/condition_variable.hpp)

- ii. perform the modification while the lock is held
- iii. execute *notify\_one* or *notify\_all* on the *condition\_variable* (the lock does not need to be held for notification)

Even if the shared variable is atomic, it must be modified under the mutex in order to correctly publish the modification to the waiting thread. Any thread that intends to wait on *condition\_variable* has to

- i. acquire a *std::unique\_lock<hpx::mutex>*, on the same mutex as used to protect the shared variable
- ii. either
  - A. check the condition, in case it was already updated and notified
  - B. execute *wait*, *wait\_for*, or *wait\_until*. The wait operations atomically release the mutex and suspend the execution of the thread.
  - C. When the condition variable is notified, a timeout expires, or a spurious wakeup occurs, the thread is awakened, and the mutex is atomically reacquired. The thread should then check the condition and resume waiting if the wake-up was spurious. or
- A. use the predicated overload of *wait*, *wait\_for*, and *wait\_until*, which takes care of the three steps above.

*hpx::condition\_variable* works only with *std::unique\_lock<hpx::mutex>*. This restriction allows for maximal efficiency on some platforms. *hpx::condition\_variable\_any* provides a condition variable that works with any [BasicLockable](#)<sup>759</sup> object, such as *std::shared\_lock*.

Condition variables permit concurrent invocation of the *wait*, *wait\_for*, *wait\_until*, *notify\_one* and *notify\_all* member functions.

The class *hpx::condition\_variable* is a [StandardLayoutType](#)<sup>760</sup>. It is not [CopyConstructible](#)<sup>761</sup>, [MoveConstructible](#)<sup>762</sup>, [CopyAssignable](#)<sup>763</sup>, or [MoveAssignable](#)<sup>764</sup>.

## Public Functions

inline **condition\_variable()**

Construct an object of type *hpx::condition\_variable*.

**~condition\_variable()** = default

Destroys the object of type *hpx::condition\_variable*.

IOW, *~condition\_variable()* can execute before a signaled thread returns from a wait. If this happens with *condition\_variable*, that waiting thread will attempt to lock the destructed mutex. To fix this, there must be shared ownership of the data members between the *condition\_variable* object and the member functions *wait* (*wait\_for*, etc.).

---

**Note:** Preconditions: There is no thread blocked on *\*this*. [Note: That is, all threads have been notified; they could subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on *\*this* once the destructor has been started, especially when the waiting threads are calling the *wait* functions in a loop or using the overloads of *wait*, *wait\_for*, or *wait\_until* that take a predicate. end note]

---

```
condition_variable(condition_variable const&) = delete
```

```
condition_variable(condition_variable&&) = delete
```

```
condition_variable &operator=(condition_variable const&) = delete
```

```
condition_variable &operator=(condition_variable&&) = delete
```

```
inline void notify_one(error_code &ec = throws) const
```

If any threads are waiting on *\*this*, calling *notify\_one* unblocks one of the waiting threads.

**Parameters**

**ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*notify\_one* returns *void*.

```
inline void notify_all(error_code &ec = throws) const
```

Unblocks all threads currently waiting for *\*this*.

**Parameters**

**ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*notify\_all* returns *void*.

```
template<typename Mutex>
```

```
inline void wait(std::unique_lock<Mutex> &lock, error_code &ec = throws)
```

*wait* causes the current thread to block until the condition variable is notified or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred())==true`).

Atomically unlocks *lock*, blocks the current executing thread, and adds it to the list of threads waiting on *\*this*. The thread will be unblocked when *notify\_all()* or *notify\_one()* is executed. It may also be unblocked spuriously. When unblocked, regardless of the reason, *lock* is reacquired and *wait* exits.

---

**Note:** 1. Calling this function if *lock.mutex()* is not locked by the current thread is undefined behavior.  
A. Calling this function if *lock.mutex()* is not the same mutex as the one used by all other threads that are currently waiting on the same condition variable is undefined behavior.

---

**Template Parameters**

**Mutex** – Type of mutex to wait on.

**Parameters**

- **lock** – *unique\_lock* that must be locked by the current thread
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*wait* returns *void*.

```
template<typename Mutex, typename Predicate>
```

```
inline void wait(std::unique_lock<Mutex> &lock, Predicate pred, error_code& = throws)
```

*wait* causes the current thread to block until the condition variable is notified or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred())==true`).

Equivalent to

```
while (!pred()) {  
    wait(lock);  
}
```

This overload may be used to ignore spurious awakenings while waiting for a specific condition to become true. Note that lock must be acquired before entering this method, and it is reacquired after *wait(lock)* exits, which means that lock can be used to guard access to *pred()*.

---

**Note:** 1. Calling this function if *lock.mutex()* is not locked by the current thread is undefined behavior.  
 A. Calling this function if *lock.mutex()* is not the same mutex as the one used by all other threads that are currently waiting on the same condition variable is undefined behavior.

---

#### Template Parameters

- **Mutex** – Type of mutex to wait on.
- **Predicate** – Type of predicate *pred* function.

#### Parameters

- **lock** – *unique\_lock* that must be locked by the current thread
- **pred** – Predicate which returns *false* if the waiting should be continued (`bool(pred())==false`). The signature of the predicate function should be equivalent to the following: `bool pred();`

#### Returns

*wait* returns *void*.

```
template<typename Mutex>
inline cv_status wait_until(std::unique_lock<Mutex> &lock, hpx::chrono::steady_time_point const
                             &abs_time, error_code &ec = throws)
```

*wait\_until* causes the current thread to block until the condition variable is notified, a specific time is reached, or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred())==true`).

Atomically releases lock, blocks the current executing thread, and adds it to the list of threads waiting on *\*this*. The thread will be unblocked when `notify_all()` or `notify_one()` is executed, or when the absolute time point *abs\_time* is reached. It may also be unblocked spuriously. When unblocked, regardless of the reason, lock is reacquired and *wait\_until* exits.

---

**Note:** 1. Calling this function if *lock.mutex()* is not locked by the current thread is undefined behavior.  
 A. Calling this function if *lock.mutex()* is not the same mutex as the one used by all other threads that are currently waiting on the same condition variable is undefined behavior.

---

#### Template Parameters

**Mutex** – Type of mutex to wait on.

#### Parameters

- **lock** – *unique\_lock* that must be locked by the current thread
- **abs\_time** – Represents the time when waiting should be stopped
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* `&#8212;` A special ‘throw on error’ *error\_code*.

#### Returns

`cv_status wait_until` returns `hpx::cv_status::timeout` if the absolute timeout specified by *abs\_time* was reached and `hpx::cv_status::no_timeout` otherwise.

```
template<typename Mutex, typename Predicate>
inline bool wait_until(std::unique_lock<Mutex> &lock, hpx::chrono::steady_time_point const
                       &abs_time, Predicate pred, error_code &ec = throws)
```

*wait\_until* causes the current thread to block until the condition variable is notified, a specific time is reached, or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred())==true`).

Equivalent to

```
while (!pred()) {  
    if (wait_until(lock, abs_time) == hpx::cv_status::timeout) {  
        return pred();  
    }  
}  
return true;
```

This overload may be used to ignore spurious wakeups.

---

**Note:** 1. Calling this function if *lock.mutex()* is not locked by the current thread is undefined behavior.  
A. Calling this function if *lock.mutex()* is not the same mutex as the one used by all other threads that are currently waiting on the same condition variable is undefined behavior.

---

#### Template Parameters

- **Mutex** – Type of mutex to wait on.
- **Predicate** – Type of predicate *pred* function.

#### Parameters

- **lock** – *unique\_lock* that must be locked by the current thread
- **abs\_time** – Represents the time when waiting should be stopped
- **pred** – Predicate which returns *false* if the waiting should be continued (`bool(pred())==false`). The signature of the predicate function should be equivalent to the following: `bool pred()`;
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

`bool wait_until` returns *false* if the predicate *pred* still evaluates to false after the *abs\_time* timeout has expired, otherwise *true*. If the timeout had already expired, evaluates and returns the result of *pred*.

```
template<typename Mutex>  
inline cv_status wait_for(std::unique_lock<Mutex> &lock, hpx::chrono::steady_duration const  
    &rel_time, error_code &ec = throws)
```

Atomically releases lock, blocks the current executing thread, and adds it to the list of threads waiting on *\*this*. The thread will be unblocked when `notify_all()` or `notify_one()` is executed, or when the relative timeout *rel\_time* expires. It may also be unblocked spuriously. When unblocked, regardless of the reason, lock is reacquired and `wait_for()` exits.

The standard recommends that a steady clock be used to measure the duration. This function may block for longer than *rel\_time* due to scheduling or resource contention delays.

---

**Note:** 1. Calling this function if *lock.mutex()* is not locked by the current thread is undefined behavior.  
A. Calling this function if *lock.mutex()* is not the same mutex as the one used by all other threads that are currently waiting on the same condition variable is undefined behavior.  
B. Even if notified under lock, this overload makes no guarantees about the state of the associated predicate when returning due to timeout.

---

#### Template Parameters

**Mutex** – Type of mutex to wait on.

#### Parameters

- **lock** – *unique\_lock* that must be locked by the current thread

- **rel\_time** – represents the maximum time to spend waiting. Note that *rel\_time* must be small enough not to overflow when added to *hpx::chrono::steady\_clock::now()*.
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*cv\_status* *hpx::cv\_status::timeout* if the relative timeout specified by *rel\_time* expired, *hpx::cv\_status::no\_timeout* otherwise.

```
template<typename Mutex, typename Predicate>
inline bool wait_for(std::unique_lock<Mutex> &lock, hpx::chrono::steady_duration const &rel_time,
    Predicate pred, error_code &ec = throws)
```

Equivalent to.

```
return wait_until(lock,
    hpx::chrono::steady_clock::now() + rel_time,
    hpx::move(pred));
```

This overload may be used to ignore spurious awakenings by looping until some predicate is satisfied (`bool(pred())==true`).

The standard recommends that a steady clock be used to measure the duration. This function may block for longer than *rel\_time* due to scheduling or resource contention delays.

---

**Note:** 1. Calling this function if *lock.mutex()* is not locked by the current thread is undefined behavior.  
 A. Calling this function if *lock.mutex()* is not the same mutex as the one used by all other threads that are currently waiting on the same condition variable is undefined behavior.

---

**Template Parameters**

- **Mutex** – Type of mutex to wait on.
- **Predicate** – Type of predicate *pred* function.

**Parameters**

- **lock** – *unique\_lock* that must be locked by the current thread
- **rel\_time** – represents the maximum time to spend waiting. Note that *rel\_time* must be small enough not to overflow when added to *hpx::chrono::steady\_clock::now()*.
- **pred** – Predicate which returns *false* if the waiting should be continued (`bool(pred())==false`). The signature of the predicate function should be equivalent to the following: `bool pred()` ;
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

`bool wait_for` returns *false* if the predicate *pred* still evaluates to *false* after the *rel\_time* timeout expired, otherwise *true*.

## Protected Functions

```
template<typename Mutex, typename Predicate>

### class **condition\_variable\_any**

*#include <condition\_variable.hpp>* The `condition_variable_any` class is a generalization of `hpx::condition_variable`. Whereas `hpx::condition_variable` works only on `std::unique_lock<std::mutex>`, a `condition_variable_any` can operate on any lock that meets the [BasicLockable](#)<sup>765</sup> requirements.

See `hpx::condition_variable` for the description of the semantics of condition variables. It is not [CopyConstructible](#)<sup>766</sup>, [MoveConstructible](#)<sup>767</sup>, [CopyAssignable](#)<sup>768</sup>, or [MoveAssignable](#)<sup>769</sup>.

## Public Functions

```
inline condition_variable_any()
```

Constructs an object of type `hpx::condition_variable_any`.

```
~condition_variable_any() = default
```

Destroys the object of type `hpx::condition_variable_any`.

It is only safe to invoke the destructor if all threads have been notified. It is not required that they have exited their respective wait functions: some threads may still be waiting to reacquire the associated lock, or may be waiting to be scheduled to run after reacquiring it.

The programmer must ensure that no threads attempt to wait on *\*this* once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or are using the overloads of the wait functions that take a predicate.

Preconditions: There is no thread blocked on *\*this*. [Note: That is, all threads have been notified; they could subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on *\*this* once the destructor has been started, especially when the waiting threads are calling the *wait* functions in a loop or using the overloads of *wait*, *wait\_for*, or *wait\_until* that take a predicate. end note]

IOW, `~condition_variable_any()` can execute before a signaled thread returns from a wait. If this happens with `condition_variable_any`, that waiting thread will attempt to lock the destructed mutex. To fix this, there must be shared ownership of the data members between the `condition_variable_any` object and the member functions *wait* (*wait\_for*, etc.).

---

```
condition_variable_any(condition_variable_any const&) = delete
```

```
condition_variable_any(condition_variable_any&&) = delete
```

```
condition_variable_any &operator=(condition_variable_any const&) = delete
```

```
condition_variable_any &operator=(condition_variable_any&&) = delete
```

```
inline void notify_one(error_code &ec = throws) const
```

If any threads are waiting on *\*this*, calling *notify\_one* unblocks one of the waiting threads.

The notifying thread does not need to hold the lock on the same mutex as the one held by the waiting thread(s); in fact doing so is a pessimization, since the notified thread would immediately block again, waiting for the notifying thread to release the lock. However, some implementations (in particular many implementations of pthreads) recognize this situation and avoid this “hurry up and wait” scenario by transferring the waiting thread from the condition variable’s queue directly to the queue of the mutex within the notify call, without waking it up.

Notifying while under the lock may nevertheless be necessary when precise scheduling of events is required, e.g. if the waiting thread would exit the program if the condition is satisfied, causing destruction of the notifying thread’s condition variable. A spurious wakeup after mutex unlock but before notify would result in notify called on a destroyed object.

---

**Note:** The effects of *notify\_one()/notify\_all()* and each of the three atomic parts of *wait()/wait\_for()/wait\_until()* (unlock+wait wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for *notify\_one()* to, for example, be delayed and unblock a thread that started waiting just after the call to *notify\_one()* was made.

---

#### Parameters

**ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

*notify\_one* returns *void*.

```
inline void notify_all(error_code &ec = throws) const
```

Unblocks all threads currently waiting for *\*this*.

The notifying thread does not need to hold the lock on the same mutex as the one held by the waiting thread(s); in fact doing so is a pessimization, since the notified thread would immediately block again, waiting for the notifying thread to release the lock.

---

**Note:** The effects of *notify\_one()/notify\_all()* and each of the three atomic parts of *wait()/wait\_for()/wait\_until()* (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for *notify\_one()* to, for example, be delayed and unblock a thread that started waiting just after the call to *notify\_one()* was made.

---

#### Parameters

**ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*notify\_all* returns *void*.

```
template<typename Lock>
```

```
inline void wait(Lock &lock, error_code &ec = throws)
```

*wait* causes the current thread to block until the condition variable is notified or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred())==true`).

Atomically unlocks lock, blocks the current executing thread, and adds it to the list of threads waiting on *this*. The thread will be unblocked when `notify_all()` or `notify_one()` is executed. It may also be unblocked spuriously. When unblocked, regardless of the reason, lock is reacquired and wait exits.

The effects of `notify_one()/notify_all()` and each of the three atomic parts of `wait()/wait_for()/wait_until()` (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

---

**Note:** If these functions fail to meet the postconditions (lock is locked by the calling thread), `std::terminate` is called. For example, this could happen if re-locking the mutex throws an exception.

---

**Template Parameters**

**Lock** – Type of *lock*.

**Parameters**

- **lock** – An object of type *Lock* that meets the [BasicLockable](#)<sup>770</sup> requirements, which must be locked by the current thread
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*wait* returns *void*.

```
template<typename Lock, typename Predicate>
```

```
inline void wait(Lock &lock, Predicate pred, error_code& = throws)
```

*wait* causes the current thread to block until the condition variable is notified or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred())==true`).

Equivalent to

```
while (!pred()) {  
    wait(lock);  
}
```

This overload may be used to ignore spurious awakenings while waiting for a specific condition to become true. Note that lock must be acquired before entering this method, and it is reacquired after `wait(lock)` exits, which means that lock can be used to guard access to `pred()`.

The effects of `notify_one()/notify_all()` and each of the three atomic parts of `wait()/wait_for()/wait_until()` (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

---

**Note:** If these functions fail to meet the postconditions (lock is locked by the calling thread), `std::terminate` is called. For example, this could happen if re-locking the mutex throws an exception.

---

#### Template Parameters

- **Lock** – Type of *lock*.
- **Predicate** – Type of *pred*.

#### Parameters

- **lock** – an object of type *Lock* that meets the [BasicLockable](#)<sup>771</sup> requirements, which must be locked by the current thread
- **pred** – predicate which returns `false` if the waiting should be continued (`bool(pred()) == false`). The signature of the predicate function should be equivalent to the following: `bool pred()`.

#### Returns

*wait* returns *void*.

```
template<typename Lock>
inline cv_status wait_until(Lock &lock, hpx::chrono::steady_time_point const &abs_time, error_code
                           &ec = throws)
```

*wait\_until* causes the current thread to block until the condition variable is notified, a specific time is reached, or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred()) == true`).

Atomically releases lock, blocks the current executing thread, and adds it to the list of threads waiting on *\*this*. The thread will be unblocked when `notify_all()` or `notify_one()` is executed, or when the absolute time point *abs\_time* is reached. It may also be unblocked spuriously. When unblocked, regardless of the reason, lock is reacquired and *wait\_until* exits.

---

**Note:** The effects of `notify_one()/notify_all()` and each of the three atomic parts of `wait()/wait_for()/wait_until()` (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

---

#### Template Parameters

**Lock** – Type of *lock*.

#### Parameters

- **lock** – an object of type *Lock* that meets the requirements of [BasicLockable](#)<sup>772</sup>, which must be locked by the current thread
- **abs\_time** – represents the time when waiting should be stopped.
- **ec** – used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

`cv_status hpx::cv_status::timeout` if the absolute timeout specified by *abs\_time* was reached, `hpx::cv_status::no_timeout` otherwise.

```
template<typename Lock, typename Predicate>
inline bool wait_until(Lock &lock, hpx::chrono::steady_time_point const &abs_time, Predicate pred,
                      error_code &ec = throws)
```

*wait\_until* causes the current thread to block until the condition variable is notified, a specific time is reached, or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred()) == true`).

Equivalent to

```

while (!pred()) {
    if (wait_until(lock, timeout_time) == hpx::cv_status::timeout) {
        return pred();
    }
}
return true;

```

This overload may be used to ignore spurious wakeups.

---

**Note:** The effects of `notify_one()/notify_all()` and each of the three atomic parts of `wait()/wait_for()/wait_until()` (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

---

#### Template Parameters

- **Lock** – Type of *lock*.
- **Predicate** – Type of *pred*.

#### Parameters

- **lock** – an object of type *Lock* that meets the requirements of [BasicLockable<sup>773</sup>](#), which must be locked by the current thread
- **abs\_time** – represents the time when waiting should be stopped.
- **pred** – predicate which returns *false* if the waiting should be continued (`bool(pred()) == false`). The signature of the predicate function should be equivalent to the following: `bool pred();`.
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

*bool false* if the predicate *pred* still evaluates to *false* after the *abs\_time* timeout expired, otherwise true. If the timeout had already expired, evaluates and returns the result of *pred*.

```

template<typename Lock>
inline cv_status wait_for(Lock &lock, hpx::chrono::steady_duration const &rel_time, error_code &ec
                        = throws)

```

Atomically releases lock, blocks the current executing thread, and adds it to the list of threads waiting on *\*this*. The thread will be unblocked when `notify_all()` or `notify_one()` is executed, or when the relative timeout *rel\_time* expires. It may also be unblocked spuriously. When unblocked, regardless of the reason, *lock* is reacquired and `wait_for()` exits.

The effects of `notify_one()/notify_all()` and each of the three atomic parts of `wait()/wait_for()/wait_until()` (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

---

**Note:** Even if notified under lock, this overload makes no guarantees about the state of the associated predicate when returning due to timeout.

---

#### Template Parameters

**Lock** – Type of *lock*.

#### Parameters

- **lock** – an object of type *Lock* that meets the [BasicLockable](#)<sup>774</sup> requirements, which must be locked by the current thread.
- **rel\_time** – an object of type *hpx::chrono::duration* representing the maximum time to spend waiting. Note that *rel\_time* must be small enough not to overflow when added to *hpx::chrono::steady\_clock::now()*.
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*cv\_status* *hpx::cv\_status::timeout* if the relative timeout specified by *rel\_time* expired, *hpx::cv\_status::no\_timeout* otherwise.

```
template<typename Lock, typename Predicate>
inline bool wait_for(Lock &lock, hpx::chrono::steady_duration const &rel_time, Predicate pred,
                    error_code &ec = throws)
```

Equivalent to.

```
return wait_until(lock,
                  hpx::chrono::steady_clock::now() + rel_time,
                  std::move(pred));
```

This overload may be used to ignore spurious awakenings by looping until some predicate is satisfied (`bool(pred()) == true`).

---

**Note:** The effects of `notify_one()/notify_all()` and each of the three atomic parts of `wait()/wait_for()/wait_until()` (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

---

**Template Parameters**

- **Lock** – Type of *lock*.
- **Predicate** – Type of *pred*.

**Parameters**

- **lock** – an object of type *Lock* that meets the [BasicLockable](#)<sup>775</sup> requirements, which must be locked by the current thread.
- **rel\_time** – an object of type *hpx::chrono::duration* representing the maximum time to spend waiting. Note that *rel\_time* must be small enough not to overflow when added to *hpx::chrono::steady\_clock::now()*.
- **pred** – predicate which returns *false* if the waiting should be continued (`bool(pred()) == false`). The signature of the predicate function should be equivalent to the following: `bool pred();`.
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*bool false* if the predicate *pred* still evaluates to *false* after the *rel\_time* timeout expired, otherwise *true*.

```
template<typename Lock, typename Predicate>
inline bool wait(Lock &lock, stop_token token, Predicate pred, error_code &ec = throws)
```

*wait* causes the current thread to block until the condition variable is notified or a spurious wakeup occurs, optionally looping until some predicate is satisfied (`bool(pred())==true`).

An interruptible wait: registers the condition\_variable\_any for the duration of wait(), to be notified if a stop request is made on the given stoken's associated stop-state; it is then equivalent to

```
while (!stoken.stop_requested()) {
    if (pred()) return true;
    wait(lock);
}
return pred();
```

Note that the returned value indicates whether *pred* evaluated to *true*, regardless of whether there was a stop requested or not.

**Note:** The effects of *notify\_one()*/*notify\_all()* and each of the three atomic parts of *wait()*/*wait\_for()*/*wait\_until()* (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for *notify\_one()* to, for example, be delayed and unblock a thread that started waiting just after the call to *notify\_one()* was made.

#### Template Parameters

- **Lock** – Type of *lock*.
- **Predicate** – Type of *pred*.

#### Parameters

- **lock** – an object of type *Lock* that meets the [BasicLockable](#)<sup>776</sup> requirements, which must be locked by the current thread
- **stoken** – a *hpx::stop\_token* to register interruption for
- **pred** – predicate which returns *false* if the waiting should be continued (*bool(pred()) == false*). The signature of the predicate function should be equivalent to the following: *bool pred()*.
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

*bool* result of *pred()*.

```
template<typename Lock, typename Predicate>
```

```
inline bool wait_until(Lock &lock, stop_token stoken, hpx::chrono::steady_time_point const
    &abs_time, Predicate pred, error_code &ec = throws)
```

*wait\_until* causes the current thread to block until the condition variable is notified, a specific time is reached, or a spurious wakeup occurs, optionally looping until some predicate is satisfied (*bool(pred()) == true*).

An interruptible wait: registers the condition\_variable\_any for the duration of wait\_until(), to be notified if a stop request is made on the given stoken's associated stop-state; it is then equivalent to

```
while (!stoken.stop_requested()) {
    if (pred())
        return true;
    if (wait_until(lock, timeout_time) == hpx::cv_status::timeout)
        return pred();
}
return pred();
```

**Note:** The effects of *notify\_one()*/*notify\_all()* and each of the three atomic parts of *wait()*/*wait\_for()*/*wait\_until()* (unlock+wait, wakeup, and lock) take place in a single total order that

can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

#### Template Parameters

- **Lock** – Type of *lock*.
- **Predicate** – Type of *pred*.

#### Parameters

- **lock** – an object of type *Lock* that meets the requirements of [BasicLockable<sup>777</sup>](#), which must be locked by the current thread.
- **stoken** – a `hpx::stop_token` to register interruption for.
- **abs\_time** – represents the time when waiting should be stopped.
- **pred** – predicate which returns *false* if the waiting should be continued (`bool(pred()) == false`). The signature of the predicate function should be equivalent to the following: `bool pred()`;
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* `&#8212`; A special ‘throw on error’ *error\_code*.

#### Returns

`bool pred()`, regardless of whether the timeout was met or stop was requested.

```
template<typename Lock, typename Predicate>
inline bool wait_for(Lock &lock, stop_token stoken, hpx::chrono::steady_duration const &rel_time,
    Predicate pred, error_code &ec = throws)
```

Equivalent to.

```
return wait_until(lock, std::move(stoken),
    hpx::chrono::steady_clock::now() + rel_time,
    std::move(pred));
```

**Note:** The effects of `notify_one()/notify_all()` and each of the three atomic parts of `wait()/wait_for()/wait_until()` (unlock+wait, wakeup, and lock) take place in a single total order that can be viewed as modification order of an atomic variable: the order is specific to this individual condition variable. This makes it impossible for `notify_one()` to, for example, be delayed and unblock a thread that started waiting just after the call to `notify_one()` was made.

#### Template Parameters

- **Lock** – Type of *lock*.
- **Predicate** – Type of *pred*.

#### Parameters

- **lock** – an object of type *Lock* that meets the [BasicLockable<sup>778</sup>](#) requirements, which must be locked by the current thread.
- **stoken** – a `hpx::stop_token` to register interruption for.
- **rel\_time** – an object of type `hpx::chrono::duration` representing the maximum time to spend waiting. Note that *rel\_time* must be small enough not to overflow when added to `hpx::chrono::steady_clock::now()`.
- **pred** – predicate which returns *false* if the waiting should be continued (`bool(pred()) == false`). The signature of the predicate function should be equivalent to the following: `bool pred()`;
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* `&#8212`; A special ‘throw on error’ *error\_code*.

#### Returns

`bool pred()`, regardless of whether the timeout was met or stop was requested.

## hpx::barrier

Defined in header [hpx/barrier.hpp](#)<sup>779</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

```
template<typename OnCompletion = detail::empty_oncompletion>
```

```
class barrier
```

*#include <barrier.hpp>* A barrier is a thread coordination mechanism whose lifetime consists of a sequence of barrier phases, where each phase allows at most an expected number of threads to block until the expected number of threads arrive at the barrier. [ Note: A barrier is useful for managing repeated tasks that are handled by multiple threads. - end note ] Each barrier phase consists of the following steps:

- The expected count is decremented by each call to `arrive` or `arrive_and_drop`.
- When the expected count reaches zero, the phase completion step is run. For the specialization with the default value of the `CompletionFunction` template parameter, the completion step is run as part of the call to `arrive` or `arrive_and_drop` that caused the expected count to reach zero. For other specializations, the completion step is run on one of the threads that arrived at the barrier during the phase.

<sup>777</sup> [https://en.cppreference.com/w/cpp/named\\_req/BasicLockable](https://en.cppreference.com/w/cpp/named_req/BasicLockable)  
<sup>778</sup> [https://en.cppreference.com/w/cpp/named\\_req/BasicLockable](https://en.cppreference.com/w/cpp/named_req/BasicLockable)  
<sup>779</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/barrier.hpp>

- When the completion step finishes, the expected count is reset to what was specified by the expected argument to the constructor, possibly adjusted by calls to `arrive_and_drop`, and the next phase starts.

Each phase defines a phase synchronization point. Threads that arrive at the barrier during the phase can block on the phase synchronization point by calling `wait`, and will remain blocked until the phase completion step is run. The phase completion step that is executed at the end of each phase has the following effects:

- Invokes the completion function, equivalent to `completion()`.
- Unblocks all threads that are blocked on the phase synchronization point.

The end of the completion step strongly happens before the returns from all calls that were unblocked by the completion step. For specializations that do not have the default value of the `CompletionFunction` template parameter, the behavior is undefined if any of the barrier object's member functions other than `wait` are called while the completion step is in progress.

Concurrent invocations of the member functions of `barrier`, other than its destructor, do not introduce data races. The member functions `arrive` and `arrive_and_drop` execute atomically.

`CompletionFunction` shall meet the `Cpp17MoveConstructible` (Table 28) and `Cpp17Destructible` (Table 32) requirements. `std::is_nothrow_invocable_v<CompletionFunction&>` shall be true.

The default value of the `CompletionFunction` template parameter is an unspecified type, such that, in addition to satisfying the requirements of `CompletionFunction`, it meets the `Cpp17DefaultConstructible` requirements (Table 27) and `completion()` has no effects.

`barrier::arrival_token` is an unspecified type, such that it meets the `Cpp17MoveConstructible` (Table 28), `Cpp17MoveAssignable` (Table 30), and `Cpp17Destructible` (Table 32) requirements.

## Public Types

using **arrival\_token** = bool

## Public Functions

inline explicit constexpr **barrier**(*std::ptrdiff\_t* expected, *OnCompletion* completion = *OnCompletion*())

Preconditions: `expected >= 0` is true and `expected <= max()` is true.

Effects: Sets both the initial expected count for each barrier phase and the current expected count for the first phase to `expected`. Initializes completion with `std::move(f)`. Starts the first phase. [Note: If `expected` is 0 this object can only be destroyed.- end note]

Throws: Any exception thrown by `CompletionFunction`'s move constructor.

**~barrier**() = default

inline *arrival\_token* **arrive**(*std::ptrdiff\_t* update = 1)

Preconditions: `update > 0` is true, and `update` is less than or equal to the expected count for the current barrier phase.

Effects: Constructs an object of type `arrival_token` that is associated with the phase synchronization point for the current phase. Then, decrements the expected count by `update`.

Synchronization: The call to `arrive` strongly happens before the start of the phase completion step for the current phase.

Error conditions: Any of the error conditions allowed for mutex types ([thread.mutex.requirements.mutex]). [Note: This call can cause the completion step for the current phase to start.- end note]

**Throws**

`system_error` – when an exception is required ([thread.req.exception]).

**Returns**

: The constructed `arrival_token` object.

inline void **wait**(*arrival\_token* &&old\_phase) const

Preconditions: arrival is associated with the phase synchronization point for the current phase or the immediately preceding phase of the same barrier object.

Effects: Blocks at the synchronization point associated with `HPX_MOVE(arrival)` until the phase completion step of the synchronization point's phase is run. [ Note: If arrival is associated with the synchronization point for a previous phase, the call returns immediately. - end note ]

**Throws**

`system_error` – when an exception is required ([thread.req.exception]). Error conditions: Any of the error conditions allowed for mutex types ([thread.mutex.requirements.mutex]).

inline void **arrive\_and\_wait**()

Effects: Equivalent to: `wait(arrive())`.

inline void **arrive\_and\_drop**()

Preconditions: The expected count for the current barrier phase is greater than zero.

Effects: Decrements the initial expected count for all subsequent phases by one. Then decrements the expected count for the current phase by one.

Synchronization: The call to `arrive_and_drop` strongly happens before the start of the phase completion step for the current phase.

**Throws**

`system_error` – when an exception is required ([thread.req.exception]). Error conditions: Any of the error conditions allowed for mutex types ([thread.mutex.requirements.mutex]). [Note: This call can cause the completion step for the current phase to start.- end note]

## `hpx::counting_semaphore`

Defined in header `hpx/semaphore.hpp`<sup>780</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

```
template<std::ptrdiff_t LeastMaxValue = PTRDIFF_MAX>
```

```
class counting_semaphore
```

*#include <counting\_semaphore.hpp>* A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Counting semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore. Unlike `hpx::mutex` a `counting_semaphore` is not tied to threads of execution &#8212; acquiring a semaphore can occur on a different thread than releasing the semaphore, for example. All operations on `counting_semaphore` can be performed concurrently and without any relation to specific threads of execution, with the exception of the destructor which cannot be performed concurrently but can be performed on a different thread.

Semaphores are lightweight synchronization primitives used to constrain concurrent access to a shared resource. They are widely used to implement other synchronization primitives and, whenever both are applicable, can be more efficient than condition variables.

A counting semaphore is a semaphore object that models a non-negative resource count.

Class template `counting_semaphore` maintains an internal counter that is initialized when the semaphore is created. The counter is decremented when a thread acquires the semaphore, and is incremented when

<sup>780</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/semaphore.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/semaphore.hpp)

a thread releases the semaphore. If a thread tries to acquire the semaphore when the counter is zero, the thread will block until another thread increments the counter by releasing the semaphore.

Specializations of `hpx::counting_semaphore` are not [DefaultConstructible](#)<sup>781</sup>, [CopyConstructible](#)<sup>782</sup>, [MoveConstructible](#)<sup>783</sup>, [CopyAssignable](#)<sup>784</sup>, or [MoveAssignable](#)<sup>785</sup>.

---

**Note:** `counting_semaphore`'s `try_acquire()` can spuriously fail.

---

### Template Parameters

**LeastMaxValue** – `counting_semaphore` allows more than one concurrent access to the same resource, for at least *LeastMaxValue* concurrent accessors. As its name indicates, the *LeastMaxValue* is the minimum max value, not the actual max value. Thus `max()` can yield a number larger than *LeastMaxValue*.

### Public Functions

`counting_semaphore(counting_semaphore const&) = delete`

`counting_semaphore &operator=(counting_semaphore const&) = delete`

`counting_semaphore(counting_semaphore&&) = delete`

`counting_semaphore &operator=(counting_semaphore&&) = delete`

explicit `counting_semaphore(std::ptrdiff_t value)`

Constructs an object of type `hpx::counting_semaphore` with the internal counter initialized to *value*.

#### Parameters

**value** – The initial value of the internal semaphore lock count. Normally this value should be zero (which is the default), values greater than zero are equivalent to the same number of signals pre-set, and negative values are equivalent to the same number of waits pre-set.

`~counting_semaphore()` = default

void `release(std::ptrdiff_t update = 1)`

Atomically increments the internal counter by the value of *update*. Any thread(s) waiting for the counter to be greater than 0, such as due to being blocked in `acquire`, will subsequently be unblocked.

---

**Note:** Synchronization: Strongly happens before invocations of *try\_acquire* that observe the result of the effects.

---

### Throws

`std::system_error` –

### Parameters

**update** – the amount to increment the internal counter by

### Pre

Both `update >= 0` and `update <= max() - counter` are *true*, where *counter* is the value of the internal counter.

bool `try_acquire()` noexcept

Tries to atomically decrement the internal counter by 1 if it is greater than 0; no blocking occurs regardless.

### Returns

*true* if it decremented the internal counter, otherwise *false*

void **acquire**()

Repeatedly performs the following steps, in order:

- Evaluates `try_acquire`. If the result is true, returns.
- Blocks on `*this` until counter is greater than zero.

**Throws**

`std::system_error` –

**Returns**

`void`.

bool **try\_acquire\_until**(`hpx::chrono::steady_time_point` const &`abs_time`)

Tries to atomically decrement the internal counter by 1 if it is greater than 0; otherwise blocks until it is greater than 0 and can successfully decrement the internal counter, or the `abs_time` time point has been passed.

**Parameters**

**`abs_time`** – the earliest time the function must wait until in order to fail

**Throws**

`std::system_error` –

**Returns**

`true` if it decremented the internal counter, otherwise `false`.

bool **try\_acquire\_for**(`hpx::chrono::steady_duration` const &`rel_time`)

Tries to atomically decrement the internal counter by 1 if it is greater than 0; otherwise blocks until it is greater than 0 and can successfully decrement the internal counter, or the `rel_time` duration has been exceeded.

**Throws**

`std::system_error` –

**Parameters**

**`rel_time`** – the minimum duration the function must wait for to fail

**Returns**

`true` if it decremented the internal counter, otherwise `false`

## Public Static Functions

static constexpr `std::ptrdiff_t` **max**() noexcept

Returns The maximum value of counter. This value is greater than or equal to *LeastMaxValue*.

**Returns**

The internal counter's maximum possible value, as a `std::ptrdiff_t`.

template<typename **Mutex** = `hpx::spinlock`, int **N** = 0>

class **counting\_semaphore\_var**

`#include <counting_semaphore.hpp>` A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Counting semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this

semaphore. Unlike `hpx::mutex` a `counting_semaphore_var` is not tied to threads of execution &#8212; acquiring a semaphore can occur on a different thread than releasing the semaphore, for example. All operations on `counting_semaphore_var` can be performed concurrently and without any relation to specific threads of execution, with the exception of the destructor which cannot be performed concurrently but can be performed on a different thread.

Semaphores are lightweight synchronization primitives used to constrain concurrent access to a shared resource. They are widely used to implement other synchronization primitives and, whenever both are applicable, can be more efficient than condition variables.

A counting semaphore is a semaphore object that models a non-negative resource count.

Class template `counting_semaphore_var` maintains an internal counter that is initialized when the semaphore is created. The counter is decremented when a thread acquires the semaphore, and is incremented when a thread releases the semaphore. If a thread tries to acquire the semaphore when the counter is zero, the thread will block until another thread increments the counter by releasing the semaphore.

Specializations of `hpx::counting_semaphore_var` are not [DefaultConstructible](#)<sup>786</sup>, [CopyConstructible](#)<sup>787</sup>, [MoveConstructible](#)<sup>788</sup>, [CopyAssignable](#)<sup>789</sup>, or [MoveAssignable](#)<sup>790</sup>.

---

**Note:** `counting_semaphore_var`'s `try_acquire()` can spuriously fail.

---

### Template Parameters

- **Mutex** – Type of mutex
- **N** – The initial value of the internal semaphore lock count.

### Public Functions

explicit **counting\_semaphore\_var**(*std::ptrdiff\_t* value = *N*)

Constructs an object of type `hpx::counting_semaphore_value` with the internal counter initialized to *N*.

#### Parameters

**value** – The initial value of the internal semaphore lock count. Normally this value should be zero, values greater than zero are equivalent to the same number of signals pre-set, and negative values are equivalent to the same number of waits pre-set. Defaults to *N* (which in turn defaults to zero).

**counting\_semaphore\_var**(*counting\_semaphore\_var* const&) = delete

*counting\_semaphore\_var* &**operator=**(*counting\_semaphore\_var* const&) = delete

void **wait**(*std::ptrdiff\_t* count = 1)

Wait for the semaphore to be signaled.

#### Parameters

**count** – The value by which the internal lock count will be decremented. At the same time this is the minimum value of the lock count at which the thread is not yielded.

bool **try\_wait**(*std::ptrdiff\_t* count = 1)

Try to wait for the semaphore to be signaled.

#### Parameters

**count** – The value by which the internal lock count will be decremented. At the same time this is the minimum value of the lock count at which the thread is not yielded.

**Returns**

*try\_wait* returns true if the calling thread was able to acquire the requested amount of credits.  
*try\_wait* returns false if not sufficient credits are available at this point in time.

void **signal**(*std::ptrdiff\_t* count = 1)

Signal the semaphore.

**Parameters**

**count** – The value by which the internal lock count will be incremented.

*std::ptrdiff\_t* **signal\_all**()

Unblock all acquirers.

**Returns**

*std::ptrdiff\_t* internal lock count after the operation.

void **release**(*std::ptrdiff\_t* update = 1)

Atomically increments the internal counter by the value of update. Any thread(s) waiting for the counter to be greater than 0, such as due to being blocked in acquire, will subsequently be unblocked.

---

**Note:** Synchronization: Strongly happens before invocations of *try\_acquire* that observe the result of the effects.

---

**Throws**

*std::system\_error* –

**Parameters**

**update** – the amount to increment the internal counter by

**Pre**

Both `update >= 0` and `update <= max() - counter` are *true*, where *counter* is the value of the internal counter.

bool **try\_acquire**() noexcept

Tries to atomically decrement the internal counter by 1 if it is greater than 0; no blocking occurs regardless.

**Returns**

*true* if it decremented the internal counter, otherwise *false*

void **acquire**()

Repeatedly performs the following steps, in order:

- Evaluates *try\_acquire*. If the result is true, returns.

Blocks on \*this until counter is greater than zero.

**Throws**

*std::system\_error* –

**Returns**

*void*.

bool **try\_acquire\_until**(*hpx::chrono::steady\_time\_point* const &abs\_time)

Tries to atomically decrement the internal counter by 1 if it is greater than 0; otherwise blocks until it is greater than 0 and can successfully decrement the internal counter, or the *abs\_time* time point has been passed.

**Parameters**

**abs\_time** – the earliest time the function must wait until in order to fail

**Throws**

*std::system\_error* –

**Returns**

*true* if it decremented the internal counter, otherwise *false*.

bool **try\_acquire\_for**(*hpx::chrono::steady\_duration* const &rel\_time)

Tries to atomically decrement the internal counter by 1 if it is greater than 0; otherwise blocks until it is greater than 0 and can successfully decrement the internal counter, or the *rel\_time* duration has been exceeded.

**Throws**

*std::system\_error* –

**Parameters**

**rel\_time** – the minimum duration the function must wait for to fail

**Returns**

*true* if it decremented the internal counter, otherwise *false*

**Public Static Functions**

static constexpr *std::ptrdiff\_t* **max**() noexcept

Returns The maximum value of counter. This value is greater than or equal to *LeastMaxValue*.

**Returns**

The internal counter's maximum possible value, as a *std::ptrdiff\_t*.

**Private Types**

using **mutex\_type** = *Mutex*

**hpx::spinlock**

Defined in header [hpx/mutex.hpp](#)<sup>791</sup>.

## Typedefs

using **spinlock** = detail::spinlock<true>

**spinlock** is a type of lock that causes a thread attempting to obtain it to check for its availability while waiting in a loop continuously.

using **spinlock\_no\_backoff** = detail::spinlock<false>

**hpx::nostopstate**, **hpx::stop\_callback**, **hpx::stop\_source**, **hpx::stop\_token**, **hpx::nostopstate\_t**

Defined in header [hpx/stop\\_token.hpp](#)<sup>792</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

## Functions

template<typename **Callback**>

**stop\_callback**(*stop\_token*, *Callback*) -> *stop\_callback*<*Callback*>

The **stop\_callback** class template provides an RAII object type that registers a callback function for an associated **hpx::stop\_token** object, such that the callback function will be invoked when the **hpx::stop\_token**'s associated **hpx::stop\_source** is requested to stop. Callback functions registered via **stop\_callback**'s constructor are invoked either in the same thread that successfully invokes *request\_stop()* for a **hpx::stop\_source** of the **stop\_callback**'s associated **hpx::stop\_token**; or if stop has already been requested prior to the constructor's registration, then the callback is invoked in the thread constructing the **stop\_callback**. More than one **stop\_callback** can be created for the same **hpx::stop\_token**, from the same or different threads concurrently. No guarantee is provided for the order in which they will be executed, but they will be invoked synchronously; except for *stop\_callback(s)* constructed after stop has already been requested for the **hpx::stop\_token**, as described previously. If an invocation of a callback exits via an exception then **hpx::terminate** is called. **hpx::stop\_callback** is not *CopyConstructible*, *CopyAssignable*, *MoveConstructible*, nor *MoveAssignable*. The template param *Callback* type must be both *invocable* and *destructible*. Any return value is ignored.

inline void **swap**(*stop\_token* &lhs, *stop\_token* &rhs) noexcept

inline void **swap**(*stop\_source* &lhs, *stop\_source* &rhs) noexcept

## Variables

constexpr *nostopstate\_t* **nostopstate** = { }

This is a constant object instance of *hpx::nostopstate\_t* for use in constructing an empty *hpx::stop\_source*, as a placeholder value in the non-default constructor.

struct **nostopstate\_t**

*#include* <*stop\_token.hpp*> Unit type intended for use as a placeholder in *hpx::stop\_source* non-default constructor, that makes the constructed *hpx::stop\_source* empty with no associated stop-state.

<sup>792</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/stop\\_token.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/stop_token.hpp)

## Public Functions

explicit **nostopstate\_t**() = default

template<typename **Callback**>

class **stop\_callback**

class **stop\_source**

*#include <stop\_token.hpp>* The `stop_source` class provides the means to issue a stop request, such as for `hpx::jthread` cancellation. A stop request made for one `stop_source` object is visible to all `stop_sources` and `hpx::stop_tokens` of the same associated stop-state; any `hpx::stop_callback(s)` registered for associated `hpx::stop_token(s)` will be invoked, and any `hpx::condition_variable_any` objects waiting on associated `hpx::stop_token(s)` will be awoken. Once a stop is requested, it cannot be withdrawn. Additional stop requests have no effect.

---

**Note:** For the purposes of `hpx::jthread` cancellation the `stop_source` object should be retrieved from the `hpx::jthread` object using `get_stop_source()`; or stop should be requested directly from the `hpx::jthread` object using `request_stop()`. This will then use the same associated stop-state as that passed into the `hpx::jthread`'s invoked function argument (i.e., the function being executed on its thread). For other uses, however, a `stop_source` can be constructed separately using the default constructor, which creates new stop-state.

---

## Public Functions

inline **stop\_source**()

inline explicit **stop\_source**(*nostopstate\_t*) noexcept

inline **stop\_source**(*stop\_source* const &rhs) noexcept

**stop\_source**(*stop\_source*&&) noexcept = default

inline *stop\_source* &**operator**=(*stop\_source* const &rhs) noexcept

## Friends

inline friend bool **operator==(***stop\_source* const &lhs, *stop\_source* const &rhs) noexcept

inline friend bool **operator!=(***stop\_source* const &lhs, *stop\_source* const &rhs) noexcept

class **stop\_token**

*#include <stop\_token.hpp>* The *stop\_token* class provides the means to check if a stop request has been made or can be made, for its associated *hpx::stop\_source* object. It is essentially a thread-safe “view” of the associated stop-state. The *stop\_token* can also be passed to the constructor of *hpx::stop\_callback*, such that the callback will be invoked if the *stop\_token*’s associated *hpx::stop\_source* is requested to stop. And *stop\_token* can be passed to the interruptible waiting functions of *hpx::condition\_variable\_any*, to interrupt the condition variable’s wait if stop is requested.

---

**Note:** A *stop\_token* object is not generally constructed independently, but rather retrieved from a *hpx::jthread* or *hpx::stop\_source*. This makes it share the same associated stop-state as the *hpx::jthread* or *hpx::stop\_source*.

### hpx::latch

Defined in header [hpx/latch.hpp](#)<sup>793</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

class **latch**

*#include <latch.hpp>* Latches are a thread coordination mechanism that allow one or more threads to block until an operation is completed. An individual latch is a single-use object; once the operation has been completed, the latch cannot be reused.

Subclassed by *hpx::lcos::local::latch*

## Public Functions

**latch**(*latch* const&) = delete

**latch**(*latch*&&) = delete

*latch* &**operator**=(*latch* const&) = delete

*latch* &**operator**=(*latch*&&) = delete

inline explicit **latch**(*std::ptrdiff\_t* const count)

Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter\_ == count.

**~latch**() = default

Requires: No threads are blocked at the synchronization point.

---

**Note:** May be called even if some threads have not yet returned from *wait()* or *count\_down\_and\_wait()*, provided that counter\_ is 0.

---

---

**Note:** The destructor might not return until all threads have exited *wait()* or *count\_down\_and\_wait()*.

---

---

**Note:** It is the caller's responsibility to ensure that no other thread enters *wait()* after one thread has called the destructor. This may require additional coordination.

---

<sup>793</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/latch.hpp>

inline void **count\_down**(std::ptrdiff\_t const update)

Decrements counter\_ by n. Does not block.

Requires: counter\_ >= n and n >= 0.

Synchronization: Synchronizes with all calls that block on this latch and with all try\_wait calls on this latch that return true .

**Throws**

Nothing. –

inline bool **try\_wait**() const noexcept

Returns: With very low probability false. Otherwise, counter == 0.

inline void **wait**() const

If counter\_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter\_ reaches 0.

**Throws**

Nothing. –

inline void **arrive\_and\_wait**(std::ptrdiff\_t update = 1)

Effects: Equivalent to: count\_down(update); wait();

## Public Static Functions

**static inline constexpr std::ptrdiff\_t() max () noexcept**

Returns: The maximum value of counter that the implementation supports.

## Protected Types

using **mutex\_type** = *hpx::spinlock*

## Protected Functions

## Protected Attributes

mutable util::cache\_line\_data<mutex\_type> **mtx\_**

mutable util::cache\_line\_data<hpx::lcos::local::detail::condition\_variable> **cond\_**

std::atomic<std::ptrdiff\_t> **counter\_**

bool **notified\_**

namespace **lcos**

namespace **local**

class **latch** : public *hpx::latch*

*#include <latch.hpp>* A latch maintains an internal counter\_ that is initialized when the latch is created. Threads may block at a synchronization point waiting for counter\_ to be decremented to 0. When counter\_ reaches 0, all such blocked threads are released.

Calls to *countdown\_and\_wait()*, *count\_down()*, *wait()*, *is\_ready()*, *count\_up()*, and *reset()* behave as atomic operations.

---

**Note:** A *hpx::latch* is not an LCO in the sense that it has no global id, and it can't be triggered using the action (parcel) mechanism. Use *hpx::distributed::latch* instead if this is required. It is just a low level synchronization primitive allowing to synchronize a given number of *threads*.

---

### Public Functions

**latch**(*latch* const&) = delete

**latch**(*latch*&&) = delete

*latch* &**operator**=(*latch* const&) = delete

*latch* &**operator**=(*latch*&&) = delete

inline explicit **latch**(*std::ptrdiff\_t* const count)

Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter\_ == count.

**~latch**() = default

Requires: No threads are blocked at the synchronization point.

---

**Note:** May be called even if some threads have not yet returned from *wait()* or *count\_down\_and\_wait()*, provided that counter\_ is 0.

---

---

**Note:** The destructor might not return until all threads have exited *wait()* or *count\_down\_and\_wait()*.

---

---

**Note:** It is the caller's responsibility to ensure that no other thread enters *wait()* after one thread has called the destructor. This may require additional coordination.

---

inline void **count\_down\_and\_wait**()

Decrements counter\_ by 1. Blocks at the synchronization point until counter\_ reaches 0.

Requires: counter\_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all *is\_ready* calls on this latch that return true.

**Throws**

Nothing. –

inline bool **is\_ready**() const noexcept

Returns: counter\_ == 0. Does not block.

**Throws**

Nothing. –

inline void **abort\_all**() constinline void **count\_up**(std::ptrdiff\_t const n)

Increments counter\_ by n. Does not block.

Requires: n &gt;= 0.

**Throws**

Nothing. –

inline void **reset**(std::ptrdiff\_t const n)

Reset counter\_ to n. Does not block.

Requires: n &gt;= 0.

**Throws**

Nothing. –

inline bool **reset\_if\_needed\_and\_count\_up**(std::ptrdiff\_t const n, std::ptrdiff\_t const count)

Effects: Equivalent to: if (is\_ready()) reset(count); count\_up(n); Returns: true if the latch was reset

**hpx::once\_flag, hpx::call\_once**Defined in header `hpx/mutex.hpp`<sup>794</sup>.See *Public API* for a list of names and headers that are part of the public *HPX* API.namespace **hpx****Functions**template<typename **F**, typename ...**Args**>void **call\_once**(once\_flag &flag, *F* &&f, *Args*&&... args)Executes the Callable object *f* exactly once, even if called concurrently, from several threads.

In detail:

- If, by the time *call\_once* is called, flag indicates that *f* was already called, *call\_once* returns right away (such a call to *call\_once* is known as passive).
- Otherwise, *call\_once* invokes `std::forward<Callable>(f)` with the arguments `std::forward<Args>(args)...` (as if by `hpx::invoke`). Unlike the `hpx::thread` constructor or `hpx::async`, the arguments are not moved or copied because they don't need to be transferred to another thread of execution. (such a call to *call\_once* is known as active).
  - If that invocation throws an exception, it is propagated to the caller of *call\_once*, and the flag is not flipped so that another call will be attempted (such a call to *call\_once* is known as exceptional).

---

<sup>794</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/mutex.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/mutex.hpp)

- If that invocation returns normally (such a call to *call\_once* is known as returning), the flag is flipped, and all other calls to *call\_once* with the same flag are guaranteed to be passive. All active calls on the same flag form a single total order consisting of zero or more exceptional calls, followed by one returning call. The end of each active call synchronizes-with the next active call in that order. The return from the returning call synchronizes-with the returns from all passive calls on the same flag: this means that all concurrent calls to *call\_once* are guaranteed to observe any side-effects made by the active call, with no additional synchronization.

---

**Note:** If concurrent calls to *call\_once* pass different functions *f*, it is unspecified which *f* will be called. The selected function runs in the same thread as the *call\_once* invocation it was passed to. Initialization of function-local statics is guaranteed to occur only once even when called from multiple threads, and may be more efficient than the equivalent code using `hpx::call_once`. The POSIX equivalent of this function is *pthread\_once*.

---

### Parameters

- **flag** – an object, for which exactly one function gets executed
- **f** – Callable object to invoke
- **args** – arguments to pass to the function

### Throws

`std::system_error` – if any condition prevents calls to *call\_once* from executing as specified or any exception thrown by *f*

struct **once\_flag**

`#include <once.hpp>` The class `hpx::once_flag` is a helper structure for `hpx::call_once`. An object of type `hpx::once_flag` that is passed to multiple calls to `hpx::call_once` allows those calls to coordinate with each other such that only one of the calls will actually run to completion. `hpx::once_flag` is neither copyable nor movable.

### Public Functions

`once_flag(once_flag const&) = delete`

`once_flag(once_flag&&) = delete`

`once_flag &operator=(once_flag const&) = delete`

`once_flag &operator=(once_flag&&) = delete`

inline **once\_flag()** noexcept

Constructs an `once_flag` object. The internal state is set to indicate that no function has been called yet.

## Private Members

`std::atomic<long> status_`

`lcos::local::event event_`

## Friends

template<typename **F**, typename ...**Args**>

friend void **call\_once**(*once\_flag* &flag, *F* &&*f*, *Args*&&... args)

Executes the Callable object *f* exactly once, even if called concurrently, from several threads.

In detail:

- If, by the time *call\_once* is called, flag indicates that *f* was already called, *call\_once* returns right away (such a call to *call\_once* is known as passive).
- Otherwise, *call\_once* invokes `std::forward<Callable>(f)` with the arguments `std::forward<Args>(args)...` (as if by `hpx::invoke`). Unlike the `hpx::thread` constructor or `hpx::async`, the arguments are not moved or copied because they don't need to be transferred to another thread of execution. (such a call to *call\_once* is known as active).
  - If that invocation throws an exception, it is propagated to the caller of *call\_once*, and the flag is not flipped so that another call will be attempted (such a call to *call\_once* is known as exceptional).
  - If that invocation returns normally (such a call to *call\_once* is known as returning), the flag is flipped, and all other calls to *call\_once* with the same flag are guaranteed to be passive. All active calls on the same flag form a single total order consisting of zero or more exceptional calls, followed by one returning call. The end of each active call synchronizes-with the next active call in that order. The return from the returning call synchronizes-with the returns from all passive calls on the same flag: this means that all concurrent calls to *call\_once* are guaranteed to observe any side-effects made by the active call, with no additional synchronization.

---

**Note:** If concurrent calls to *call\_once* pass different functions *f*, it is unspecified which *f* will be called. The selected function runs in the same thread as the *call\_once* invocation it was passed to. Initialization of function-local statics is guaranteed to occur only once even when called from multiple threads, and may be more efficient than the equivalent code using `hpx::call_once`. The POSIX equivalent of this function is *pthread\_once*.

---

### Parameters

- **flag** – an object, for which exactly one function gets executed
- **f** – Callable object to invoke
- **args** – arguments to pass to the function

### Throws

`std::system_error` – if any condition prevents calls to *call\_once* from executing as specified or any exception thrown by *f*

## hpx::shared\_mutex

Defined in header `hpx/shared_mutex.hpp`<sup>795</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Typedefs

using **shared\_mutex** = detail::shared\_mutex<>

The *shared\_mutex* class is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. In contrast to other mutex types which facilitate exclusive access, a *shared\_mutex* has two levels of access:

- *shared* - several threads can share ownership of the same mutex.
- *exclusive* - only one thread can own the mutex.

If one thread has acquired the exclusive lock (through *lock*, *try\_lock*), no other threads can acquire the lock (including the shared). If one thread has acquired the shared lock (through *lock\_shared*, *try\_lock\_shared*), no other thread can acquire the exclusive lock, but can acquire the shared lock. Only when the exclusive lock has not been acquired by any thread, the shared lock can be acquired by multiple threads. Within one thread, only one lock (shared or exclusive) can be acquired at the same time. Shared mutexes are especially useful when shared data can be safely read by any number of threads simultaneously, but a thread may only write the same data when no other thread is reading or writing at the same time. The *shared\_mutex* class satisfies all requirements of *SharedMutex* and *StandardLayoutType*.

## hpx::mutex, hpx::timed\_mutex

Defined in header `hpx/mutex.hpp`<sup>796</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

class **mutex**

*#include <mutex.hpp>* *mutex* class is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. *mutex* offers exclusive, non-recursive ownership semantics:

- A calling thread owns a mutex from the time that it successfully calls either *lock* or *try\_lock* until it calls *unlock*.
- When a thread owns a *mutex*, all other threads will block (for calls to *lock*) or receive a *false* return value (for *try\_lock*) if they attempt to claim ownership of the *mutex*.
- A calling thread must not own the *mutex* prior to calling *lock* or *try\_lock*.

<sup>795</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/shared\\_mutex.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/shared_mutex.hpp)

<sup>796</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/mutex.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/mutex.hpp)

The behavior of a program is undefined if a *mutex* is destroyed while still owned by any threads, or a thread terminates while owning a *mutex*. The *mutex* class satisfies all requirements of [Mutex](#)<sup>797</sup> and [StandardLayoutType](#)<sup>798</sup>.

`hpx::mutex` is neither copyable nor movable.

Subclassed by `hpx::timed_mutex`

## Public Functions

**mutex**(*mutex* const&) = delete

`hpx::mutex` is neither copyable nor movable

**mutex**(*mutex*&&) = delete

*mutex* &**operator**=(*mutex* const&) = delete

*mutex* &**operator**=(*mutex*&&) = delete

inline HPX\_HOST\_DEVICE\_CONSTEXPR **mutex**(char const\*const = "") noexcept

Constructs the *mutex*. The *mutex* is in unlocked state after the constructor completes.

---

**Note:** Because the default constructor is *constexpr*, static mutexes are initialized as part of static non-local initialization, before any dynamic non-local initialization begins. This makes it safe to lock a *mutex* in a constructor of any static object.

---

## Parameters

**description** – description of the *mutex*.

**~mutex()**

Destroys the *mutex*. The behavior is undefined if the *mutex* is owned by any thread or if any thread terminates while holding any ownership of the *mutex*.

void **lock**(char const \*description, *error\_code* &ec = *throws*)

Locks the *mutex*. If another thread has already locked the *mutex*, a call to *lock* will block execution until the lock is acquired. If *lock* is called by a thread that already owns the *mutex*, the behavior is undefined: for example, the program may deadlock. `hpx::mutex` can detect the invalid usage and throws a `std::system_error` with error condition `resource_deadlock_would_occur` instead of deadlocking. Prior *unlock()* operations on the same *mutex* synchronize- with (as defined in `std::memory_order`) this operation.

---

**Note:** *lock()* is usually not called directly: `std::unique_lock`, `std::scoped_lock`, and `std::lock_guard` are used to manage exclusive locking.

---

## Parameters

- **description** – Description of the *mutex*
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

## Returns

void *lock* returns *void*.

inline void **lock**(*error\_code* &ec = *throws*)

Locks the *mutex*. If another thread has already locked the *mutex*, a call to *lock* will block execution until the lock is acquired. If *lock* is called by a thread that already owns the *mutex*, the behavior is undefined: for example, the program may deadlock. *hpx::mutex* can detect the invalid usage and throws a *std::system\_error* with error condition *resource\_deadlock\_would\_occur* instead of deadlocking. Prior *unlock()* operations on the same *mutex* synchronize - with(as defined in *std::memory\_order*) this operation.

---

**Note:** *lock()* is usually not called directly: *std::unique\_lock*, *std::scoped\_lock*, and *std::lock\_guard* are used to manage exclusive locking. This overload essentially calls `void lock(char const* description, error_code& ec =throws);` with *description* as *mutex::lock*.

---

#### Parameters

**ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

*void lock* returns *void*.

bool **try\_lock**(char const \*description, *error\_code* &ec = *throws*)

Tries to lock the *mutex*. Returns immediately. On successful lock acquisition returns *true*, otherwise returns *false*. This function is allowed to fail spuriously and return *false* even if the *mutex* is not currently locked by any other thread. If *try\_lock* is called by a thread that already owns the *mutex*, the behavior is undefined. Prior *unlock()* operation on the same *mutex* synchronizes-with (as defined in *std::memory\_order*) this operation if it returns *true*. Note that prior *lock()* does not synchronize with this operation if it returns *false*.

#### Parameters

- **description** – Description of the *mutex*
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

bool *try\_lock* returns *true* on successful lock acquisition, otherwise returns *false*.

inline bool **try\_lock**(*error\_code* &ec = *throws*)

Tries to lock the *mutex*. Returns immediately. On successful lock acquisition returns *true*, otherwise returns *false*. This function is allowed to fail spuriously and return *false* even if the *mutex* is not currently locked by any other thread. If *try\_lock* is called by a thread that already owns the *mutex*, the behavior is undefined. Prior *unlock()* operation on the same *mutex* synchronizes-with (as defined in *std::memory\_order*) this operation if it returns *true*. Note that prior *lock()* does not synchronize with this operation if it returns *false*.

---

**Note:** This overload essentially calls

```
void try_lock(char const* description,
              error_code& ec = throws);
```

with *description* as *mutex::try\_lock*.

---

#### Parameters

**ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

bool *try\_lock* returns *true* on successful lock acquisition, otherwise returns *false*.

void **unlock**(*error\_code* &ec = *throws*)

Unlocks the *mutex*. The *mutex* must be locked by the current thread of execution, otherwise, the behavior is undefined. This operation *synchronizes-with* (as defined in *std::memory\_order*) any subsequent *lock* operation that obtains ownership of the same *mutex*.

**Parameters**

**ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*unlock* returns *void*.

class **timed\_mutex** : private *hpx::mutex*

*#include <mutex.hpp>* The *timed\_mutex* class is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. In a manner similar to *mutex*, *timed\_mutex* offers exclusive, non-recursive ownership semantics. In addition, *timed\_mutex* provides the ability to attempt to claim ownership of a *timed\_mutex* with a timeout via the member functions *try\_lock\_for()* and *try\_lock\_until()*. The *timed\_mutex* class satisfies all requirements of *TimedMutex*<sup>799</sup> and *StandardLayoutType*<sup>800</sup>.

*hpx::timed\_mutex* is neither copyable nor movable.

## Public Functions

**timed\_mutex**(*timed\_mutex* const&) = delete

*hpx::timed\_mutex* is neither copyable nor movable

**timed\_mutex**(*timed\_mutex*&&) = delete

*timed\_mutex* &**operator**=(*timed\_mutex* const&) = delete

*timed\_mutex* &**operator**=(*timed\_mutex*&&) = delete

**timed\_mutex**(char const \*const description = "")

Constructs a *timed\_mutex*. The mutex is in unlocked state after the call.

**Parameters**

**description** – Description of the *timed\_mutex*.

**~timed\_mutex**()

Destroys the *timed\_mutex*. The behavior is undefined if the mutex is owned by any thread or if any thread terminates while holding any ownership of the mutex.

bool **try\_lock\_until**(*hpx::chrono::steady\_time\_point* const &*abs\_time*, char const \*description, *error\_code* &ec = *throws*)

Tries to lock the mutex. Blocks until specified *abs\_time* has been reached or the lock is acquired, whichever comes first. On successful lock acquisition returns *true*, otherwise returns *false*. If *abs\_time* has already passed, this function behaves like *try\_lock()*. As with *try\_lock()*, this function is allowed to fail spuriously and return *false* even if the mutex was not locked by any other thread at some point before *abs\_time*. Prior *unlock()* operation on the same mutex *synchronizes-with* (as defined in *std::memory\_order*) this operation if it returns *true*. If *try\_lock\_until* is called by a thread that already owns the mutex, the behavior is undefined.

**Parameters**

- **abs\_time** – time point to block until
- **description** – Description of the *timed\_mutex*
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

`bool try_lock_until` returns *true* if the lock was acquired successfully, otherwise *false*.

```
inline bool try_lock_until(hpx::chrono::steady_time_point const &abs_time, error_code &ec =
    throws)
```

Tries to lock the mutex. Blocks until specified *abs\_time* has been reached or the lock is acquired, whichever comes first. On successful lock acquisition returns *true*, otherwise returns *false*. If *abs\_time* has already passed, this function behaves like `try_lock()`. As with `try_lock()`, this function is allowed to fail spuriously and return *false* even if the mutex was not locked by any other thread at some point before *abs\_time*. Prior `unlock()` operation on the same mutex *synchronizes-with* (as defined in *std::memory\_order*) this operation if it returns *true*. If `try_lock_until` is called by a thread that already owns the mutex, the behavior is undefined.

---

**Note:** This overload essentially calls

```
bool try_lock_until(
    hpx::chrono::steady_time_point const& abs_time,
    char const* description, error_code& ec = throws);
```

with *description* as `mutex::try_lock_until`.

---

**Parameters**

- **abs\_time** – time point to block until
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

`bool try_lock_until` returns *true* if the lock was acquired successfully, otherwise *false*.

```
inline bool try_lock_for(hpx::chrono::steady_duration const &rel_time, char const *description,
    error_code &ec = throws)
```

Tries to lock the mutex. Blocks until specified *rel\_time* has elapsed or the lock is acquired, whichever comes first. On successful lock acquisition returns *true*, otherwise returns *false*. If *rel\_time* is less or equal *rel\_time.zero()*, the function behaves like `try_lock()`. This function may block for longer than *rel\_time* due to scheduling or resource contention delays. As with `try_lock()`, this function is allowed to fail spuriously and return *false* even if the mutex was not locked by any other thread at some point during *rel\_time*. Prior `unlock()` operation on the same mutex *synchronizes-with* (as defined in *std::memory\_order*) this operation if it returns *true*. If `try_lock_for` is called by a thread that already owns the mutex, the behavior is undefined.

**Parameters**

- **rel\_time** – minimum duration to block for
- **description** – Description of the timed\_mutex
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

`bool try_lock_for` returns *true* if the lock was acquired successfully, otherwise *false*.

```
inline bool try_lock_for(hpx::chrono::steady_duration const &rel_time, error_code &ec = throws)
```

Tries to lock the mutex. Blocks until specified *rel\_time* has elapsed or the lock is acquired, whichever comes first. On successful lock acquisition returns *true*, otherwise returns *false*. If *rel\_time* is less or equal *rel\_time.zero()*, the function behaves like `try_lock()`. This function may block for longer than *rel\_time* due to scheduling or resource contention delays. As with `try_lock()`, this function is allowed to fail spuriously and return *false* even if the mutex was not locked by any other thread at some point during *rel\_time*. Prior `unlock()` operation on the same mutex *synchronizes-with* (as defined in

*std::memory\_order*) this operation if it returns *true*. If *try\_lock\_for* is called by a thread that already owns the mutex, the behavior is undefined.

---

**Note:** This overload essentially calls

```
bool try_lock_for(
    hpx::chrono::steady_duration const& rel_time,
    char const* description, error_code& ec = throws)
```

with *description* as `mutex::try_lock_for`.

---

#### Parameters

- **rel\_time** – minimum duration to block for
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

`bool try_lock_for` returns *true* if the lock was acquired successfully, otherwise *false*.

void **lock**(char const \*description, error\_code &ec = throws)

Locks the mutex. If another thread has already locked the mutex, a call to `lock` will block execution until the lock is acquired. If `lock` is called by a thread that already owns the mutex, the behavior is undefined: for example, the program may deadlock. `hpx::mutex` can detect the invalid usage and throws a *std::system\_error* with error condition *resource\_deadlock\_would\_occur* instead of *deadlocking*. Prior `unlock()` operations on the same mutex synchronize- with (as defined in *std::memory\_order*) this operation.

---

**Note:** `lock()` is usually not called directly: *std::unique\_lock*, *std::scoped\_lock*, and *std::lock\_guard* are used to manage exclusive locking.

---

#### Parameters

- **description** – Description of the *mutex*
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

#### Returns

`void lock` returns *void*.

inline void **lock**(error\_code &ec = throws)

Locks the mutex. If another thread has already locked the mutex, a call to `lock` will block execution until the lock is acquired. If `lock` is called by a thread that already owns the mutex, the behavior is undefined: for example, the program may deadlock. `hpx::mutex` can detect the invalid usage and throws a *std::system\_error* with error condition *resource\_deadlock\_would\_occur* instead of *deadlocking*. Prior `unlock()` operations on the same mutex synchronize - with(as defined in *std::memory\_order*) this operation.

---

**Note:** `lock()` is usually not called directly: *std::unique\_lock*, *std::scoped\_lock*, and *std::lock\_guard* are used to manage exclusive locking. This overload essentially calls `void lock(char const* description, error_code& ec =throws);` with *description* as `mutex::lock`.

---

#### Parameters

- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

`void lock` returns *void*.

bool **try\_lock**(char const \*description, error\_code &ec = throws)

Tries to lock the *mutex*. Returns immediately. On successful lock acquisition returns *true*, otherwise returns *false*. This function is allowed to fail spuriously and return *false* even if the *mutex* is not currently locked by any other thread. If *try\_lock* is called by a thread that already owns the *mutex*, the behavior is undefined. Prior *unlock()* operation on the same *mutex* synchronizes-with (as defined in *std::memory\_order*) this operation if it returns *true*. Note that prior *lock()* does not synchronize with this operation if it returns *false*.

**Parameters**

- **description** – Description of the *mutex*
- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

bool *try\_lock* returns *true* on successful lock acquisition, otherwise returns *false*.

inline bool **try\_lock**(error\_code &ec = throws)

Tries to lock the *mutex*. Returns immediately. On successful lock acquisition returns *true*, otherwise returns *false*. This function is allowed to fail spuriously and return *false* even if the *mutex* is not currently locked by any other thread. If *try\_lock* is called by a thread that already owns the *mutex*, the behavior is undefined. Prior *unlock()* operation on the same *mutex* synchronizes-with (as defined in *std::memory\_order*) this operation if it returns *true*. Note that prior *lock()* does not synchronize with this operation if it returns *false*.

---

**Note:** This overload essentially calls

```
void try_lock(char const* description,
              error_code& ec = throws);
```

with *description* as *mutex::try\_lock*.

---

**Parameters**

- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

bool *try\_lock* returns *true* on successful lock acquisition, otherwise returns *false*.

void **unlock**(error\_code &ec = throws)

Unlocks the *mutex*. The *mutex* must be locked by the current thread of execution, otherwise, the behavior is undefined. This operation *synchronizes-with* (as defined in *std::memory\_order*) any subsequent *lock* operation that obtains ownership of the same *mutex*.

**Parameters**

- **ec** – Used to hold error code value originated during the operation. Defaults to *throws* &#8212; A special ‘throw on error’ *error\_code*.

**Returns**

*unlock* returns *void*.

namespace **threads**

## Functions

*thread\_id* **get\_self\_id**() noexcept  
The function *get\_self\_id* returns the HPX thread id of the current thread (or zero if the current thread is not a HPX thread).

*thread\_self* \***get\_self\_ptr**() noexcept  
The function *get\_self\_ptr* returns a pointer to the (OS thread specific) self reference to the current HPX thread.

## hpx/synchronization/sliding\_semaphore.hpp

Defined in header `hpx/synchronization/sliding_semaphore.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

## Typedefs

```
using sliding_semaphore = sliding_semaphore_var<>
```

```
template<typename Mutex = hpx::spinlock>
```

```
class sliding_semaphore_var
```

*#include <sliding\_semaphore.hpp>* A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Sliding semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore. The difference to a counting semaphore is that a sliding semaphore will not limit the number of threads which are allowed to proceed, but will make sure that the difference between the (arbitrary) number passed to set and wait does not exceed a given threshold.

## Public Functions

**sliding\_semaphore\_var**(*sliding\_semaphore\_var* const&) = delete

*sliding\_semaphore\_var* &**operator**=(*sliding\_semaphore\_var* const&) = delete

**sliding\_semaphore\_var**(*sliding\_semaphore\_var*&&) = delete

*sliding\_semaphore\_var* &**operator**=(*sliding\_semaphore\_var*&&) = delete

inline explicit **sliding\_semaphore\_var**(*std::int64\_t* max\_difference, *std::int64\_t* lower\_limit = 0)  
noexcept

Construct a new sliding semaphore.

### Parameters

- **max\_difference** – [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.
- **lower\_limit** – [in] The initial lower limit.

inline void **set\_max\_difference**(*std::int64\_t* max\_difference, *std::int64\_t* lower\_limit = 0) noexcept

Set/Change the difference that will cause the semaphore to trigger

### Parameters

- **max\_difference** – [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.
- **lower\_limit** – [in] The initial lower limit.

inline void **wait**(*std::int64\_t* upper\_limit)

Wait for the semaphore to be signaled.

### Parameters

- **upper\_limit** – [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower\_limit which was set by *signal()* is larger than the max\_difference.

inline bool **try\_wait**(*std::int64\_t* upper\_limit = 1)

Try to wait for the semaphore to be signaled.

### Parameters

- **upper\_limit** – [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower\_limit which was set by *signal()* is larger than the max\_difference.

### Returns

The function returns true if the calling thread would not block if it was calling *wait()*.

inline void **signal**(*std::int64\_t* lower\_limit)

Signal the semaphore.

### Parameters

- **lower\_limit** – [in] The new lower limit. This will update the current lower limit of this semaphore. It will also re-schedule all suspended threads for which their associated upper limit is not larger than the lower limit plus the max\_difference.

inline *std::int64\_t* **signal\_all**()

## Private Types

<sup>802</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

## Functions

```
template<typename F, typename ...Ts>
constexpr util::invoke_result_t<F, Ts&&...> invoke(F &&f, Ts&&... vs)
    noexcept(noexcept(HPX_INVOKE(HPX_FORWARD(F,
    f), HPX_FORWARD(Ts, vs)...)))
```

Invokes the given callable object `f` with the content of the argument pack `vs`

---

**Note:** This function is similar to `std::invoke` (C++17)

---

### Parameters

- **f** – Requires to be a callable object. If `f` is a member function pointer, the first argument in the pack will be treated as the callee (this object).
- **vs** – An arbitrary pack of arguments

### Throws

`std::exception` – like objects thrown by call to object `f` with the argument types `vs`.

### Returns

The result of the callable object when it's called with the given argument types.

```
template<typename R, typename F, typename ...Ts>
constexpr R invoke_r(F &&f, Ts&&... vs) noexcept(noexcept(HPX_INVOKE(HPX_FORWARD(F, f),
    HPX_FORWARD(Ts, vs)...)))
```

### Template Parameters

**R** – The result type of the function when it's called with the content of the given argument types `vs`.

namespace **functional**

struct **invoke**

### Public Functions

```
template<typename F, typename ...Ts>
inline constexpr util::invoke_result_t<F, Ts&&...> operator()(F &&f, Ts&&... vs) const noexcept(
    noexcept(HPX_INVOKE(HPX_FORWARD(F, f), HPX_FORWARD(Ts, vs)...)))
```

```
template<typename R>
```

```
struct invoke_r
```

## Public Functions

```
template<typename F, typename ...Ts>
inline constexpr R operator() (F &&f, Ts&&... vs) const
    noexcept(noexcept(HPX_INVOKE(HPX_FORWARD(F,f),
    HPX_FORWARD(Ts, vs)...)))
```

## hpx::is\_invocable, hpx::is\_invocable\_r

Defined in header `hpx/type_traits.hpp`<sup>803</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Variables

```
template<typename F, typename ...Ts>
constexpr bool is_invocable_v = is_invocable<F, Ts...>::value

template<typename R, typename F, typename ...Ts>
constexpr bool is_invocable_r_v = is_invocable_r<R, F, Ts...>::value

template<typename F, typename ...Ts>
constexpr bool is_nothrow_invocable_v = is_nothrow_invocable<F, Ts...>::value

template<typename F, typename ...Ts>
```

```
struct is_invocable : public hpx::detail::is_invocable_impl<F&&(Ts&&...)>
```

*#include <is\_invocable.hpp>* Determines whether *F* can be invoked with the arguments *Ts...*. Formally, determines whether

```
INVOKE(std::declval<F>(), std::declval<Ts>()...)
```

is well-formed when treated as an unevaluated operand, where *INVOKE* is the operation defined in *Callable*.

*F*, *R* and all types in the parameter pack *Ts* shall each be a complete type, (possibly cv-qualified) void, or an array of unknown bound. Otherwise, the behavior is undefined. If an instantiation of a template above depends, directly or indirectly, on an incomplete type, and that instantiation could yield a different result if that type were hypothetically completed, the behavior is undefined.

```
template<typename R, typename F, typename ...Ts>
```

```
struct is_invocable_r : public hpx::detail::is_invocable_r_impl<F&&(Ts&&...), R>
```

*#include <is\_invocable.hpp>* Determines whether *F* can be invoked with the arguments *Ts...* to yield a result that is convertible to *R* and the implicit conversion does not bind a reference to a temporary object (since C++23). If *R* is cv void, the result can be any type. Formally, determines whether

```
INVOKE<R>(std::declval<F>(), std::declval<Ts>()...)
```

<sup>803</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/type\\_traits.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/type_traits.hpp)

is well-formed when treated as an unevaluated operand, where *INVOKE* is the operation defined in *Callable*. Determines whether *F* can be invoked with the arguments *Ts...*. Formally, determines whether

```
INVOKE(std::declval<F>(), std::declval<Ts>()...)
```

is well-formed when treated as an unevaluated operand, where *INVOKE* is the operation defined in *Callable*.

*F*, *R* and all types in the parameter pack *Ts* shall each be a complete type, (possibly cv-qualified) void, or an array of unknown bound. Otherwise, the behavior is undefined. If an instantiation of a template above depends, directly or indirectly, on an incomplete type, and that instantiation could yield a different result if that type were hypothetically completed, the behavior is undefined.

```
template<typename F, typename ...Ts>
```

```
struct is_nothrow_invocable : public hpx::detail::is_nothrow_invocable_impl<F(Ts...), is_invocable_v<F,  
Ts...>>
```

## thread\_pool\_util

See *Public API* for a list of names and headers that are part of the public HPX API.

### hpx/thread\_pool\_util/thread\_pool\_suspension\_helpers.hpp

Defined in header hpx/thread\_pool\_util/thread\_pool\_suspension\_helpers.hpp.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx
```

```
namespace threads
```

## Functions

```
hpx::future<void> resume_processing_unit(thread_pool_base &pool, std::size_t virt_core)
```

Resumes the given processing unit. When the processing unit has been resumed the returned future will be ready.

---

**Note:** Can only be called from an HPX thread. Use `resume_processing_unit_cb` or to resume the processing unit from outside HPX. Requires that the pool has `threads::policies::enable_elasticity` set.

---

### Parameters

- **pool** – [in] The thread pool to resume a processing unit on.
- **virt\_core** – [in] The processing unit on the pool to be resumed. The processing units are indexed starting from 0.

### Returns

A `future<void>` which is ready when the given processing unit has been resumed.

```
void resume_processing_unit_cb(thread_pool_base &pool, hpx::function<void()> callback,  
std::size_t virt_core, error_code &ec = throws)
```

Resumes the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been resumed.

---

**Note:** Requires that the pool has `threads::policies::enable_elasticity` set.

---

**Parameters**

- **pool** – [in] The thread pool to resume a processing unit on.
- **callback** – [in] Callback which is called when the processing unit has been suspended.
- **virt\_core** – [in] The processing unit to resume.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`hpx::future<void> suspend_processing_unit(thread_pool_base &pool, std::size_t virt_core)`

Suspends the given processing unit. When the processing unit has been suspended the returned future will be ready.

---

**Note:** Can only be called from an HPX thread. Use `suspend_processing_unit_cb` or to suspend the processing unit from outside HPX. Requires that the pool has `threads::policies::enable_elasticity` set.

---

**Parameters**

- **pool** – [in] The thread pool to suspend a processing unit from.
- **virt\_core** – [in] The processing unit on the pool to be suspended. The processing units are indexed starting from 0.

**Throws**

`hpx::exception` – if called from outside the HPX runtime.

**Returns**

A `future<void>` which is ready when the given processing unit has been suspended.

`void suspend_processing_unit_cb(hpx::function<void()> callback, thread_pool_base &pool, std::size_t virt_core, error_code &ec = throws)`

Suspends the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been suspended.

---

**Note:** Requires that the pool has `threads::policies::enable_elasticity` set.

---

**Parameters**

- **pool** – [in] The thread pool to suspend a processing unit from.
- **callback** – [in] Callback which is called when the processing unit has been suspended.
- **virt\_core** – [in] The processing unit to suspend.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`hpx::future<void> resume_pool(thread_pool_base &pool)`

Resumes the thread pool. When the all OS threads on the thread pool have been resumed the returned future will be ready.

---

**Note:** Can only be called from an HPX thread. Use `resume_cb` or `resume_direct` to suspend the pool from outside HPX.

---

**Parameters**

**pool** – [in] The thread pool to resume.

**Throws**

`hpx::exception` – if called from outside the HPX runtime.

**Returns**

A `future<void>` which is ready when the thread pool has been resumed.

```
void resume_pool_cb(thread_pool_base &pool, hpx::function<void()> callback, error_code &ec =
    throws)
```

Resumes the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been resumed.

**Parameters**

- **pool** – [in] The thread pool to resume.
- **callback** – [in] called when the thread pool has been resumed.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
hpx::future<void> suspend_pool(thread_pool_base &pool)
```

Suspends the thread pool. When the all OS threads on the thread pool have been suspended the returned future will be ready.

---

**Note:** Can only be called from an HPX thread. Use `suspend_cb` or `suspend_direct` to suspend the pool from outside HPX. A thread pool cannot be suspended from an HPX thread running on the pool itself.

---

**Parameters**

**pool** – [in] The thread pool to suspend.

**Throws**

*hpx::exception* – if called from outside the HPX runtime.

**Returns**

A `future<void>` which is ready when the thread pool has been suspended.

```
void suspend_pool_cb(thread_pool_base &pool, hpx::function<void()> callback, error_code &ec =
    throws)
```

Suspends the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been suspended.

---

**Note:** A thread pool cannot be suspended from an HPX thread running on the pool itself.

---

**Parameters**

- **pool** – [in] The thread pool to suspend.
- **callback** – [in] called when the thread pool has been suspended.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws**

*hpx::exception* – if called from an HPX thread which is running on the pool itself.

## thread\_support

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx::unlock\_guard

Defined in header `hpx/mutex.hpp`<sup>804</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

```
template<typename Lock>
```

```
class relock_guard
```

*#include <unlock\_guard.hpp>* The class *relock\_guard* is a mutex wrapper that provides a convenient mechanism for reacquiring a lock that was released by an *unlock\_guard*, for the duration of a scoped block.

*relock\_guard* performs the opposite functionality of *unlock\_guard* within an already-unlocked section.

When a *relock\_guard* object is created, it takes ownership of the underlying Lock associated with the given *unlock\_guard* by locking it. When control leaves the scope in which the *relock\_guard* object was created, the *relock\_guard* is destructed and the underlying Lock is released again (unlocked), restoring the unlocked state managed by the enclosing *unlock\_guard*. In this way, *relock\_guard* allows a temporarily locked section to be nested within an unlocked section created by *unlock\_guard*.

---

**Note:** *relock\_guard* is non-copyable and non-movable.

---

#### Template Parameters

**Lock** – The type of the lockable object managed by the associated *unlock\_guard*.

#### Public Functions

```
inline explicit relock_guard(unlock_guard<Lock> &ul) noexcept
```

```
relock_guard(relock_guard const&) = delete
```

```
relock_guard(relock_guard&&) = delete
```

```
relock_guard &operator=(relock_guard const&) = delete
```

```
relock_guard &operator=(relock_guard&&) = delete
```

```
inline ~relock_guard()
```

---

<sup>804</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/mutex.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/mutex.hpp)

## Private Members

*unlock\_guard*<Lock> &ul\_

template<typename Lock>

class **unlock\_guard**

*#include <unlock\_guard.hpp>* The class *unlock\_guard* is a mutex wrapper that provides a convenient mechanism for releasing a mutex for the duration of a scoped block.

*unlock\_guard* performs the opposite functionality of *lock\_guard*.

When a *lock\_guard* object is created, it attempts to take ownership of the mutex it is given. When control leaves the scope in which the *lock\_guard* object was created, the *lock\_guard* is destructed and the mutex is released. Accordingly, when an *unlock\_guard* object is created, it attempts to release the ownership of the mutex it is given. So, when control leaves the scope in which the *unlock\_guard* object was created, the *unlock\_guard* is destructed and the mutex is owned again. In this way, the mutex is unlocked in the constructor and locked in the destructor, so that one can have an unlocked section within a locked one.

---

**Note:** *unlock\_guard* is non-copyable and non-movable.

---

## Template Parameters

**Lock** – The type of the lockable object managed by the *unlock\_guard*.

## Public Functions

```

## threading

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx::jthread

Defined in header `hpx/jthread.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

## Functions

```
inline void swap(jthread &lhs, jthread &rhs) noexcept
```

```
class jthread
```

*#include <jthread.hpp>* The class *jthread* represents a single thread of execution. It has the same general behavior as `hpx::thread`, except that *jthread* automatically rejoins on destruction, and can be cancelled/stopped in certain situations. Threads begin execution immediately upon construction of the associated thread object (pending any OS scheduling delays), starting at the top-level function provided as a constructor argument. The return value of the top-level function is ignored and if it terminates by throwing an exception, `hpx::terminate` is called. The top-level function may communicate its return value or an exception to the caller via `hpx::promise` or by modifying shared variables (which may require synchronization, see `hpx::mutex` and `hpx::atomic`) Unlike `hpx::thread`, the *jthread* logically holds an internal private member of type `hpx::stop_source`, which maintains a shared stop-state. The *jthread* constructor accepts a function that takes a `hpx::stop_token` as its first argument, which will be passed in by the *jthread* from its internal *stop\_source*. This allows the function to check if stop has been requested during its execution, and return if it has. `hpx::jthread` objects may also be in the state that does not represent any thread (after default construction, move from, detach, or join), and a thread of execution may be not associated with any *jthread* objects (after detach). No two `hpx::jthread` objects may represent the same thread of execution; `hpx::jthread` is not *CopyConstructible* or *CopyAssignable*, although it is *MoveConstructible* and *MoveAssignable*.

## Public Types

    Checks whether the thread is joinable, i.e. potentially running in parallel context  
`void join()`  
    waits for the thread to finish its execution  
`inline void detach()`  
    permits the thread to execute independently of the thread handle  
`id get_id() const noexcept`  
    returns the id of the thread  
`inline native_handle_type native_handle() const`  
    returns the underlying implementation-defined thread handle  
`void interrupt(bool flag = true) const`  
`bool interruption_requested() const`  
`hpx::future<void> get_future(error_code &ec = throws) const`  
`std::size_t get_thread_data() const`  
`std::size_t set_thread_data(std::size_t) const`

### Public Static Functions

`static unsigned int hardware_concurrency() noexcept`  
    returns the number of concurrent threads supported by the implementation  
`static void interrupt(id const&, bool flag = true)`

```

namespace **this\_thread**

## Functions

*thread::id* **get\_id**() noexcept

Returns the id of the current thread.

void **yield**() noexcept

Provides a hint to the implementation to reschedule the execution of threads, allowing other threads to run.

---

**Note:** The exact behavior of this function depends on the implementation, in particular on the mechanics of the OS scheduler in use and the state of the system. For example, a first-in-first-out realtime scheduler (SCHED\_FIFO in Linux) would suspend the current thread and put it on the back of the queue of the same-priority threads that are ready to run (and if there are no other threads at the same priority, yield has no effect).

---

void **yield\_to**(*thread::id* const&) noexcept

*threads::thread\_priority* **get\_priority**() noexcept

*std::ptrdiff\_t* **get\_stack\_size**() noexcept

void **interruption\_point**()

bool **interruption\_enabled**()

bool **interruption\_requested**()

void **interrupt**()

void **sleep\_until**(*hpx::chrono::steady\_time\_point* const &*abs\_time*)

Blocks the execution of the current thread until specified *abs\_time* has been reached.

It is recommended to use the clock tied to *abs\_time*, in which case adjustments of the clock may be taken into account. Thus, the duration of the block might be more or less than *abs\_time*-*Clock::now*() at the time of the call, depending on the direction of the adjustment and whether it is honored by the implementation. The function also may block until after *abs\_time* has been reached due to process scheduling or resource contention delays.

### Parameters

**abs\_time** – absolute time to block until

```
inline void sleep_for(hpx::chrono::steady_duration const &rel_time)
```

Blocks the execution of the current thread for at least the specified *rel\_time*. This function may block for longer than *rel\_time* due to scheduling or resource contention delays.

It is recommended to use a steady clock to measure the duration. If an implementation uses a system clock instead, the wait time may also be sensitive to clock adjustments.

#### Parameters

**rel\_time** – time duration to sleep

```
std::size_t get_thread_data()
```

```
std::size_t set_thread_data(std::size_t)
```

```
class disable_interruption
```

#### Public Functions

```
disable_interruption(disable_interruption&&) = delete

namespace **hpx**

namespace **this\_thread**

## Functions

```
threads::thread_restart_state suspend(threads::thread_schedule_state state, threads::thread_id_type
                                     nextid, threads::thread_description const &description =
                                     threads::thread_description("this_thread::suspend"),
                                     hpx::error_code &ec = hpx::throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

---

**Note:** Must be called from within a HPX-thread.

---

## Throws

If `!&ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

```
inline threads::thread_restart_state suspend(threads::thread_schedule_state state =
                                             threads::thread_schedule_state::pending,
                                             threads::thread_description const &description =
                                             threads::thread_description("this_thread::suspend"),
                                             hpx::error_code &ec = hpx::throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

---

**Note:** Must be called from within a HPX-thread.

---

#### Throws

If `– &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

```
threads::thread_restart_state suspend(hpx::chrono::steady_time_point const &abs_time,
                                     threads::thread_id_type id, threads::thread_description const
                                     &description =
                                     threads::thread_description("this_thread::suspend"),
                                     hpx::error_code &ec = hpx::throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

---

**Note:** Must be called from within a HPX-thread.

---

#### Throws

If `– &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

```
inline threads::thread_restart_state suspend(hpx::chrono::steady_time_point const &abs_time,
                                             threads::thread_description const &description =
                                             threads::thread_description("this_thread::suspend"),
                                             hpx::error_code &ec = hpx::throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

---

**Note:** Must be called from within a HPX-thread.

---

#### Throws

If `– &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

```
inline threads::thread_restart_state suspend(hpx::chrono::steady_duration const &rel_time,
                                             threads::thread_description const &description =
                                             threads::thread_description("this_thread::suspend"),
                                             hpx::error_code &ec = hpx::throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

---

**Note:** Must be called from within a HPX-thread.

---

#### Throws

If `– &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

```
inline threads::thread_restart_state suspend(hpx::chrono::steady_duration const &rel_time,
                                             threads::thread_id_type const &id,
                                             threads::thread_description const &description =
                                             threads::thread_description("this_thread::suspend"),
                                             hpx::error_code &ec = hpx::throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

---

**Note:** Must be called from within a HPX-thread.

---

#### Throws

If `– &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

```
inline threads::thread_restart_state suspend(std::uint64_t ms, threads::thread_description const
                                             &description =
                                             threads::thread_description("this_thread::suspend"),
                                             hpx::error_code &ec = hpx::throws)
```

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given time (specified in milliseconds).

---

**Note:** Must be called from within a HPX-thread.

---

#### Throws

If `– &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

```
threads::thread_pool_base *get_pool(hpx::error_code &ec = hpx::throws)
```

Returns a pointer to the pool that was used to run the current thread

**Throws**

If `ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::error::yield_aborted` if it is signaled with `wait_aborted`. If called outside a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::error::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::error::invalid_status`.

namespace **threads**

**Functions**

```
thread_state set_thread_state(thread_id_type const &id, thread_schedule_state state =
    thread_schedule_state::pending, thread_restart_state stateex =
    thread_restart_state::signaled, thread_priority priority =
    thread_priority::normal, bool retry_on_active = true, hpx::error_code
    &ec = hpx::throws)
```

Set the thread state of the *thread* referenced by the thread\_id *id*.

---

**Note:** If the thread referenced by the parameter *id* is in `thread_state::active` state this function schedules a new thread which will set the state of the thread as soon as it is not active anymore. The function returns `thread_state::active` in this case.

---

---

**Note:** As long as *ec* is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of `hpx::exception`.

---

**Parameters**

- **id** – [in] The thread id of the thread the state should be modified for.
- **state** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **stateex** – [in] The new extended state to be set for the thread referenced by the *id* parameter.
- **priority** – [in]
- **retry\_on\_active** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns**

This function returns the previous state of the thread referenced by the *id* parameter. It will return one of the values as defined by the `thread_state` enumeration. If the thread is not known to the thread-manager the return value will be `thread_state::unknown`.

```
thread_id_ref_type set_thread_state(thread_id_type const &id, hpx::chrono::steady_time_point
    const &abs_time, std::atomic<bool> *started,
    thread_schedule_state state = thread_schedule_state::pending,
    thread_restart_state stateex = thread_restart_state::timeout,
    thread_priority priority = thread_priority::normal, bool
    retry_on_active = true, hpx::error_code &ec = hpx::throws)
```

Set the thread state of the *thread* referenced by the thread\_id *id*.

Set a timer to set the state of the given *thread* to the given new value after it expired (at the given time)

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread the state should be modified for.
- **abs\_time** – [in] Absolute point in time for the new thread to be run
- **started** – [in,out] A helper variable allowing to track the state of the timer helper thread
- **state** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **stateex** – [in] The new extended state to be set for the thread referenced by the *id* parameter.
- **priority** – [in]
- **retry\_on\_active** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

```
inline thread_id_ref_type set_thread_state(thread_id_type const &id,
                                         hpx::chrono::steady_time_point const &abs_time,
                                         thread_schedule_state state =
                                         thread_schedule_state::pending, thread_restart_state
                                         stateex = thread_restart_state::timeout, thread_priority
                                         priority = thread_priority::normal, bool retry_on_active
                                         = true, hpx::error_code& = throws)
```

```
inline thread_id_ref_type set_thread_state(thread_id_type const &id, hpx::chrono::steady_duration
                                         const &rel_time, thread_schedule_state state =
                                         thread_schedule_state::pending, thread_restart_state
                                         stateex = thread_restart_state::timeout, thread_priority
                                         priority = thread_priority::normal, bool retry_on_active
                                         = true, hpx::error_code &ec = hpx::throws)
```

Set the thread state of the *thread* referenced by the thread\_id *id*.

Set a timer to set the state of the given *thread* to the given new value after it expired (after the given duration)

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread the state should be modified for.
- **rel\_time** – [in] Time duration after which the new thread should be run
- **state** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **stateex** – [in] The new extended state to be set for the thread referenced by the *id* parameter.
- **priority** – [in]
- **retry\_on\_active** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

```
thread_state get_thread_state(thread_id_type const &id, hpx::error_code &ec = hpx::throws)
noexcept
```

The function `get_thread_backtrace` is part of the thread related API allows to query the currently stored

thread back trace (which is captured during thread suspension).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*. The function *get\_thread\_state* is part of the thread related API. It queries the state of one of the threads known to the thread-manager.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread being queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.
- **id** – [in] The thread id of the thread the state should be modified for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns the currently captured stack back trace of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the zero.

#### Returns

This function returns the thread state of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be *terminated*.

*std::size\_t* **get\_thread\_phase**(thread\_id\_type const &id, *hpx::error\_code* &ec = *hpx::throws*) noexcept

The function *get\_thread\_phase* is part of the thread related API. It queries the phase of one of the threads known to the thread-manager.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread the phase should be modified for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns the thread phase of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be ~0.

bool **get\_thread\_interruption\_enabled**(thread\_id\_type const &id, *hpx::error\_code* &ec = *hpx::throws*)

Returns whether the given thread can be interrupted at this point.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread which should be queried.

- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function returns *true* if the given thread can be interrupted at this point in time. It will return *false* otherwise.

```
bool set_thread_interruption_enabled(thread_id_type const &id, bool enable, hpx::error_code
                                     &ec = hpx::throws)
```

Set whether the given thread can be interrupted at this point.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **id** – [in] The thread id of the thread which should receive the new value.
- **enable** – [in] This value will determine the new interruption enabled status for the given thread.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function returns the previous value of whether the given thread could have been interrupted.

```
bool get_thread_interruption_requested(thread_id_type const &id, hpx::error_code &ec =
                                       hpx::throws)
```

Returns whether the given thread has been flagged for interruption.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **id** – [in] The thread id of the thread which should be queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function returns *true* if the given thread was flagged for interruption. It will return *false* otherwise.

```
void interrupt_thread(thread_id_type const &id, bool flag, hpx::error_code &ec = hpx::throws)
```

Flag the given thread for interruption.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **id** – [in] The thread id of the thread which should be interrupted.
- **flag** – [in] The flag encodes whether the thread should be interrupted (if it is *true*), or 'uninterrupted' (if it is *false*).
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

---

```
inline void interrupt_thread(thread_id_type const &id, hpx::error_code &ec = hpx::throws)
```

```
void interruption_point(thread_id_type const &id, hpx::error_code &ec = hpx::throws)
```

Interrupt the current thread at this point if it was canceled. This will throw a `thread_interrupted` exception, which will cancel the thread.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread which should be interrupted.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
threads::thread_priority get_thread_priority(thread_id_type const &id, hpx::error_code &ec = hpx::throws) noexcept
```

Return priority of the given thread

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread whose priority is queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
std::ptrdiff_t get_stack_size(thread_id_type const &id, hpx::error_code &ec = hpx::throws) noexcept
```

Return stack size of the given thread

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread whose priority is queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
threads::thread_pool_base *get_pool(thread_id_type const &id, hpx::error_code &ec = hpx::throws)
```

Returns a pointer to the pool that was used to run the current thread

#### Throws

If – &ec != &throws, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield\_aborted* if it is signaled with *wait\_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null\_thread\_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid\_status*.

## hpx/threading\_base/thread\_data.hpp

Defined in header `hpx/threading_base/thread_data.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

### Functions

```
constexpr thread_data *get_thread_id_data(thread_id_ref_type const &tid) noexcept
constexpr thread_data *get_thread_id_data(thread_id_type const &tid) noexcept
constexpr tracing::region_init_data get_region_init_data(thread_data const*) noexcept
constexpr tracing::fiber_region_init_data get_fiber_region_init_data(thread_data const*)
                                           noexcept
```

class **thread\_data** : public thread\_data\_reference\_counting

*#include <thread\_data.hpp>* A *thread* is the representation of a HPX thread. It's a first class object in HPX. In our implementation this is a user level thread running on top of one of the OS threads spawned by the *thread-manager*.

A *thread* encapsulates:

- A thread status word (see the functions *thread::get\_state* and *thread::set\_state*)
- A function to execute (the thread function)
- A frame (in this implementation this is a block of memory used as the threads stack)
- A block of registers (not implemented yet)

Generally, *threads* are not created or executed directly. All functionality related to the management of *threads* is implemented by the thread-manager.

### Public Types

```
using spinlock_pool = util::spinlock_pool<thread_data>
```

### Public Functions

```
thread_data(thread_data const&) = delete
```

```
thread_data(thread_data&&) = delete
```

```
thread_data &operator=(thread_data const&) = delete
```

```
thread_data &operator=(thread_data&&) = delete
```

```
inline thread_state get_state(std::memory_order const order = std::memory_order_acquire) const
    noexcept
```

The `get_state` function queries the state of this thread instance.

---

**Note:** This function will seldom be used directly. Most of the time the state of a thread will be retrieved by using the function `threadmanager::get_state`.

---

### Returns

This function returns the current state of this thread. It will return one of the values as defined by the `thread_state` enumeration.

```
inline thread_state set_state(thread_schedule_state const state, thread_restart_state state_ex =
    thread_restart_state::unknown, std::memory_order const load_order
    = std::memory_order_acquire, std::memory_order const
    exchange_order = std::memory_order_acq_rel) const noexcept
```

The `set_state` function changes the state of this thread instance.

---

**Note:** This function will seldom be used directly. Most of the time the state of a thread will have to be changed using the thread-manager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status `threadmanager::set_state` should be used.

---

### Parameters

- **state** – [in] The new state to be set for the thread.
- **state\_ex** – [in]
- **load\_order** – [in]
- **exchange\_order** – [in]

```
inline bool set_state_tagged(thread_schedule_state const newstate, thread_state const
    &prev_state, thread_state &new_tagged_state, std::memory_order
    const exchange_order = std::memory_order_acq_rel) const
    noexcept
```

```
inline bool restore_state(thread_state const new_state, thread_state const old_state,
    std::memory_order const load_order = std::memory_order_relaxed,
    std::memory_order const load_exchange =
    std::memory_order_acq_rel) const noexcept
```

The `restore_state` function changes the state of this thread instance depending on its current state. It will change the state atomically only if the current state is still the same as passed as the second parameter. Otherwise, it won't touch the thread state of this instance.

---

**Note:** This function will seldom be used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status `threadmanager::set_state` should be used.

---

### Parameters

- **new\_state** – [in] The new state to be set for the thread.
- **old\_state** – [in] The old state of the thread which still has to be the current state.
- **load\_order** – [in]
- **load\_exchange** – [in]

**Returns**

This function returns *true* if the state has been changed successfully

```
inline bool restore_state(thread_schedule_state const new_state, thread_restart_state const
                           state_ex, thread_state old_state, std::memory_order const
                           load_exchange = std::memory_order_acq_rel) const noexcept

char const *get_fiber_name() const noexcept

inline constexpr thread_priority get_priority() const noexcept

inline void set_priority(thread_priority const priority) noexcept

inline constexpr bool is_background() const noexcept

inline void set_is_background() noexcept

inline constexpr bool interruption_requested() const noexcept

inline constexpr bool interruption_enabled() const noexcept

inline bool set_interruption_enabled(bool enable) noexcept

inline void interrupt(bool const flag = true)

bool interruption_point(bool throw_on_interrupt = true)

bool add_thread_exit_callback(function<void()> const &f)

void run_thread_exit_callbacks()

void free_thread_exit_callbacks()

inline bool runs_as_child(std::memory_order const mo = std::memory_order_acquire) const
                           noexcept

inline constexpr bool is_stackless() const noexcept

void destroy_thread() override

inline constexpr policies::scheduler_base *get_scheduler_base() const noexcept

inline constexpr std::uint16_t get_last_worker_thread_num() const noexcept

inline void set_last_worker_thread_num(std::uint16_t const last_worker_thread_num)
                                       noexcept

inline constexpr std::ptrdiff_t get_stack_size() const noexcept

inline thread_stacksize get_stack_size_enum() const noexcept

template<typename ThreadQueue>
inline constexpr ThreadQueue &get_queue() noexcept

inline coroutine_type::result_type operator() (hpx::execution_base::this_thread::detail::agent_storage
                                                *agent_storage)
```

Execute the thread function.

**Returns**

This function returns the thread state the thread should be scheduled from this point on.

The thread manager will use the returned value to set the thread's scheduling status.

inline coroutine\_type::result\_type **invoke\_directly**()

Directly execute the thread function (inline)

#### Returns

This function returns the thread state the thread should be scheduled from this point on.  
The thread manager will use the returned value to set the thread's scheduling status.

inline virtual thread\_id\_type **get\_thread\_id**() const

inline virtual std::size\_t **get\_thread\_phase**() const noexcept

virtual std::size\_t **get\_thread\_data**() const = 0

virtual std::size\_t **set\_thread\_data**(std::size\_t data) = 0

virtual void **init**() = 0

virtual void **rebind**(thread\_init\_data &init\_data) = 0

inline hpx::tracing::task\_timer\_data **get\_timer\_data**() const noexcept

inline void **set\_timer\_data**(hpx::tracing::task\_timer\_data data) noexcept

**thread\_data**(thread\_init\_data &init\_data, void \*queue, std::ptrdiff\_t stacksize, bool is\_stackless = false, thread\_id\_addrf addrf = thread\_id\_addrf::yes)

**~thread\_data**() override

virtual void **destroy**() noexcept = 0

## Public Static Functions

static inline constexpr std::uint64\_t **get\_component\_id**() noexcept

Return the id of the component this thread is running in.

static inline constexpr threads::thread\_description **get\_description**() noexcept

static inline constexpr threads::thread\_description **set\_description**(threads::thread\_description) noexcept

static inline constexpr threads::thread\_description **get\_lco\_description**() noexcept

static inline constexpr threads::thread\_description **set\_lco\_description**(threads::thread\_description) noexcept

static char const \***get\_safe\_description**(threads::thread\_description const &description, char const \*fallback = "<unknown>") noexcept

static inline constexpr std::uint32\_t **get\_parent\_locality\_id**() noexcept

Return the locality of the parent thread.

static inline constexpr thread\_id\_type **get\_parent\_thread\_id**() noexcept

Return the thread id of the parent thread.

static inline constexpr std::size\_t **get\_parent\_thread\_phase**() noexcept

Return the phase of the parent thread.

static inline constexpr util::backtrace const \***get\_backtrace**() noexcept

static inline constexpr util::backtrace const \***set\_backtrace**(util::backtrace const\*) noexcept

## Protected Functions

```
inline thread_restart_state set_state_ex(thread_restart_state const new_state,  
                                         std::memory_order const load_order =  
                                         std::memory_order_acquire, std::memory_order const  
                                         load_exchange = std::memory_order_acq_rel) const  
                                         noexcept
```

The `set_state` function changes the extended state of this thread instance.

---

**Note:** This function will seldom be used directly. Most of the time the state of a thread will have to be changed using the threadmanager.

---

### Parameters

- **new\_state** – [in] The new extended state to be set for the thread.
- **load\_order** – [in]
- **load\_exchange** – [in]

```
void rebind_base(thread_init_data &init_data)
```

## hpx/threading\_base/thread\_pool\_base.hpp

Defined in header `hpx/threading_base/thread_pool_base.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

### Functions

`std::ostream &operator<<(std::ostream &os, thread_pool_base const &thread_pool)`

class **thread\_pool\_base**

*#include <thread\_pool\_base.hpp>* The base class used to manage a pool of OS threads.

### Public Functions

virtual void **suspend\_processing\_unit\_direct**(std::size\_t virt\_core, error\_code &ec = throws)  
= 0

Suspends the given processing unit. Blocks until the processing unit has been suspended.

#### Parameters

- **virt\_core** – [in] The processing unit on the pool to be suspended. The processing units are indexed starting from 0.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

virtual void **resume\_processing\_unit\_direct**(std::size\_t virt\_core, error\_code &ec = throws)  
= 0

Resumes the given processing unit. Blocks until the processing unit has been resumed.

#### Parameters

- **virt\_core** – [in] The processing unit on the pool to be resumed. The processing units are indexed starting from 0.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

virtual void **resume\_direct**(*error\_code* &ec = *throws*) = 0

Resumes the thread pool. Blocks until all OS threads on the thread pool have been resumed.

**Parameters**

**ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

virtual void **suspend\_direct**(*error\_code* &ec = *throws*) = 0

Suspends the thread pool. Blocks until all OS threads on the thread pool have been suspended.

---

**Note:** A thread pool cannot be suspended from an HPX thread running on the pool itself.

---

**Parameters**

**ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws**

*hpx::exception* – if called from an HPX thread which is running on the pool itself.

struct **thread\_pool\_init\_parameters**

## Public Functions

```
inline thread_pool_init_parameters(std::string const &name, std::size_t index,
                                   policies::scheduler_mode mode, std::size_t num_threads,

## hpx::scoped\_annotation

Defined in header [hpx/functional.hpp](#)<sup>806</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

struct **scoped\_annotation**

*#include <scoped\_annotation.hpp>* *scoped\_annotation* associates a *name* with a section of code (scope). It can be used to visualize code execution in profiling tools like *Intel VTune*, *Apex Profiler*, etc. That allows analyzing performance to figure out which part(s) of code is (are) responsible for performance degradation, etc.

### Public Functions

```

scoped_annotation(scoped_annotation const&) = delete

scoped_annotation(scoped_annotation&&) = delete

scoped_annotation &operator=(scoped_annotation const&) = delete

scoped_annotation &operator=(scoped_annotation&&) = delete

inline explicit constexpr scoped_annotation(char const*) noexcept

template<typename F>
inline explicit constexpr scoped_annotation(F&&) noexcept

inline ~scoped_annotation()

```

<sup>806</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

## hpx::annotated\_function

Defined in header [hpx/functional.hpp](#)<sup>807</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

```
template<typename F>  
constexpr F &&annotated_function(F &&f, char const* = nullptr) noexcept
```

Returns a function annotated with the given annotation.

Annotating includes setting the thread description per thread id.

#### Parameters

**f** – Function to annotate

```
template<typename F>  
constexpr F &&annotated_function(F &&f, std::string const&) noexcept
```

## hpx/threading\_base/register\_thread.hpp

Defined in header `hpx/threading_base/register_thread.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **threads**

### Functions

```
template<typename F>  
thread_function_type make_thread_function(F &&f)
```

```
template<typename F, typename ...Ts>  
thread_function_type make_thread_function_nullary(F &&f, Ts&&... ts)
```

```
void register_thread(threads::thread_init_data &data, threads::thread_pool_base *pool,  
                    threads::thread_id_ref_type &id, error_code &ec = hpx::throws)
```

Create a new *thread* using the given data.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **data** – [in] The data to use for creating the thread.

---

<sup>807</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/functional.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/functional.hpp)

- **pool** – [in] The thread pool to use for launching the work.
- **id** – [out] The id of the newly created thread (if applicable)
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws**

*invalid\_status* – if the runtime system has not been started yet.

**Returns**

This function will return the internal id of the newly created HPX-thread.

```
threads::thread_id_ref_type register_thread(threads::thread_init_data &data,
                                             threads::thread_pool_base *pool, error_code &ec =
                                             hpx::throws)
```

```
void register_thread(threads::thread_init_data &data, threads::thread_id_ref_type &id, error_code
                    &ec = throws)
```

Create a new *thread* using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **data** – [in] The data to use for creating the thread.
- **id** – [out] The id of the newly created thread (if applicable)
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws**

*invalid\_status* – if the runtime system has not been started yet.

**Returns**

This function will return the internal id of the newly created HPX-thread.

```
threads::thread_id_ref_type register_thread(threads::thread_init_data &data, error_code &ec =
                                             throws)
```

```
thread_id_ref_type register_work(threads::thread_init_data &data, threads::thread_pool_base *pool,
                                error_code &ec = hpx::throws)
```

Create a new work item using the given data.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **data** – [in] The data to use for creating the thread.
- **pool** – [in] The thread pool to use for launching the work.
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Throws**

*invalid\_status* – if the runtime system has not been started yet.

```
thread_id_ref_type register_work(threads::thread_init_data &data, error_code &ec = throws)
```

Create a new work item using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

- **data** – [in] The data to use for creating the thread.
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Throws

*invalid\_status* – if the runtime system has not been started yet.

**hpx::get\_worker\_thread\_num, hpx::get\_local\_worker\_thread\_num, hpx::get\_local\_worker\_thread\_num, hpx::get\_thread\_pool\_num, hpx::get\_thread\_pool\_num**

Defined in header [hpx/runtime.hpp](#)<sup>808</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

### Functions

*std::size\_t* **get\_worker\_thread\_num**() noexcept

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by *get\_os\_thread\_count()*).

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

*std::size\_t* **get\_worker\_thread\_num**(*error\_code* &ec) noexcept

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by *get\_os\_thread\_count()*). It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

---

<sup>808</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

**Parameters**

**ec** – [in,out] this represents the error status on exit (obsolete, ignored).

`std::size_t get_local_worker_thread_num()` noexcept

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

`std::size_t get_local_worker_thread_num(error_code &ec)` noexcept

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

**Parameters**

**ec** – [in,out] this represents the error status on exit (obsolete, ignored).

`std::size_t get_thread_pool_num()` noexcept

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

`std::size_t get_thread_pool_num(error_code &ec)` noexcept

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

---

**Note:** The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

---

---

**Note:** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

---

#### Parameters

**ec** – [in,out] this represents the error status on exit (obsolete, ignored).

namespace **threads**

### hpx/threading\_base/thread\_description.hpp

Defined in header `hpx/threading_base/thread_description.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

#### Functions

`std::ostream &operator<<(std::ostream&, thread_description const&)`

`std::string as_string(thread_description const &desc)`

`threads::thread_description get_thread_description(thread_id_type const &id, error_code &ec = throws)`

The function `get_thread_description` is part of the thread related API allows to query the description of one of the threads known to the thread-manager.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The thread id of the thread being queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns the description of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the string “<unknown>”.

`threads::thread_description set_thread_description(thread_id_type const &id,  
threads::thread_description const &desc =  
threads::thread_description(), error_code &ec  
= throws)`

```
threads::thread_description get_thread_lco_description(thread_id_type const &id, error_code
&ec = throws)
```

```
threads::thread_description set_thread_lco_description(thread_id_type const &id,
threads::thread_description const &desc
= threads::thread_description(),
error_code &ec = throws)
```

```
struct thread_description
```

## Public Types

## hpx/threading\_base/threading\_base\_fwd.hpp

Defined in header `hpx/threading_base/threading_base_fwd.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
namespace threads
```

## Functions

```
thread_data *get_self_id_data() noexcept
```

The function *get\_self\_id\_data* returns the data of the HPX thread id associated with the current thread (or nullptr if the current thread is not a HPX thread).

```
thread_self &get_self()
```

The function *get\_self* returns a reference to the (OS thread specific) self reference to the current HPX thread.

```
thread_self *get_self_ptr() noexcept
```

The function *get\_self\_ptr* returns a pointer to the (OS thread specific) self reference to the current HPX thread.

```
thread_self_impl_type *get_ctx_ptr()
```

The function *get\_ctx\_ptr* returns a pointer to the internal data associated with each coroutine.

```
thread_self *get_self_ptr_checked(error_code &ec = throws)
```

The function *get\_self\_ptr\_checked* returns a pointer to the (OS thread specific) self reference to the current HPX thread.

```
thread_id_type get_self_id() noexcept
```

The function *get\_self\_id* returns the HPX thread id of the current thread (or zero if the current thread is not a HPX thread).

```
HPX_DEPRECATED_V (2, 0, "hpx::threads::get_outer_self_id is deprecated,  
use " "hpx::threads::get_self_id instead") inline thread_id_type get_outer_self_id() noexcept
```

The function *get\_outer\_self\_id* returns the HPX thread id of the current outer thread (or zero if the current thread is not a HPX thread). This now always returns the same as *get\_self\_id*, even for directly executed threads.

thread\_id\_type **get\_parent\_id()** noexcept

The function *get\_parent\_id* returns the HPX thread id of the current thread's parent (or zero if the current thread is not a HPX thread).

---

**Note:** This function will return a meaningful value only if the code was compiled with HPX\_HAVE\_THREAD\_PARENT\_REFERENCE being defined.

---

std::size\_t **get\_parent\_phase()** noexcept

The function *get\_parent\_phase* returns the HPX phase of the current thread's parent (or zero if the current thread is not a HPX thread).

---

**Note:** This function will return a meaningful value only if the code was compiled with HPX\_HAVE\_THREAD\_PARENT\_REFERENCE being defined.

---

std::ptrdiff\_t **get\_self\_stacksize()** noexcept

The function *get\_self\_stacksize* returns the stack size of the current thread (or zero if the current thread is not a HPX thread).

thread\_stacksize **get\_self\_stacksize\_enum()** noexcept

The function *get\_self\_stacksize\_enum* returns the stack size of the /.

std::uint32\_t **get\_parent\_locality\_id()** noexcept

The function *get\_parent\_locality\_id* returns the id of the locality of the current thread's parent (or zero if the current thread is not a HPX thread).

---

**Note:** This function will return a meaningful value only if the code was compiled with HPX\_HAVE\_THREAD\_PARENT\_REFERENCE being defined.

---

std::uint64\_t **get\_self\_component\_id()** noexcept

The function *get\_self\_component\_id* returns the lva of the component the current thread is acting on

---

**Note:** This function will return a meaningful value only if the code was compiled with HPX\_HAVE\_THREAD\_TARGET\_ADDRESS being defined.

---

namespace **policies**

namespace **tracing**

## threadmanager

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/threadmanager/threadmanager.hpp

Defined in header `hpx/threadmanager/threadmanager.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

class **threadmanager**

*#include <threadmanager.hpp>* The *thread-manager* class is the central instance of management for all (non-depleted) threads

### Public Types

using **notification\_policy\_type** = *threads::policies::callback\_notifier*

using **pool\_type** = *std::unique\_ptr<thread\_pool\_base>*

using **pool\_vector** = *std::vector<pool\_type>*

### Public Functions

**threadmanager**(*hpx::util::runtime\_configuration &rtcfg\_, notification\_policy\_type &notifier, detail::network\_background\_callback\_type network\_background\_callback = detail::network\_background\_callback\_type()*)

**threadmanager**(*threadmanager const&*) = delete

**threadmanager**(*threadmanager&&*) = delete

*threadmanager &operator*=(*threadmanager const&*) = delete

*threadmanager &operator*=(*threadmanager&&*) = delete

**~threadmanager**()

void **init**() const

void **create\_pools**()

void **print\_pools**(*std::ostream&*) const

FIXME move to private and add `&#8212;hpx:printpools` cmd line option.

*thread\_pool\_base &default\_pool*() const

```
thread_pool_base &get_pool(std::string const &pool_name) const
```

```
thread_pool_base &get_pool(pool_id_type const &pool_id) const
```

```
thread_pool_base &get_pool(std::size_t thread_index) const
```

```
bool pool_exists(std::string const &pool_name) const
```

```
bool pool_exists(std::size_t pool_index) const
```

```
thread_id_ref_type register_work(thread_init_data &data, error_code &ec = throws) const
```

The function *register\_work* adds a new work item to the thread manager. It doesn't immediately create a new *thread*, it just adds the task parameters (function, initial state and description) to the internal management data structures. The thread itself will be created when the number of existing threads drops below the number of threads specified by the constructors *max\_count* parameter.

#### Parameters

- **data** – [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.
- **ec** –

```
void register_thread(thread_init_data &data, thread_id_ref_type &id, error_code &ec = throws) const
```

The function *register\_thread* adds a new work item to the thread manager. It creates a new *thread*, adds it to the internal management data structures, and schedules the new thread, if appropriate.

#### Parameters

- **data** – [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.
- **id** – [out] This parameter will hold the id of the created thread. This id is guaranteed to be validly initialized before the thread function is executed.
- **ec** –

```
bool run() const
```

Run the thread manager's work queue. This function instantiates the specified number of OS threads in each pool. All OS threads are started to execute the function *tfunc*.

#### Returns

The function returns *true* if the thread manager has been started successfully, otherwise it returns *false*.

```
void stop(bool blocking = true) const
```

Forcefully stop the thread-manager.

#### Parameters

**blocking** –

```
bool is_busy() const
```

```
bool is_idle() const
```

```
void wait() const
```

```
bool wait_for(hpx::chrono::steady_duration const &rel_time) const
```

```
template<typename StopToken>
```

```
inline bool wait_for(StopToken &&stop_token, hpx::chrono::steady_duration const &rel_time) const
```

void **suspend**() const

void **resume**() const

*hpx::state* **status**() const

Return whether the thread manager is still running This returns the “minimal state”, i.e. the state of the least advanced thread pool

*std::int64\_t* **get\_thread\_count**(*thread\_schedule\_state* state = *thread\_schedule\_state::unknown*,  
                                  *thread\_priority* priority = *thread\_priority::default\_*, *std::size\_t*  
                                  num\_thread = static\_cast<*std::size\_t*>(-1), bool reset = false)  
const

return the number of HPX-threads with the given state

---

**Note:** This function locks the internal OS lock in the thread manager

---

*std::int64\_t* **get\_idle\_core\_count**() const

*mask\_type* **get\_idle\_core\_mask**() const

*std::int64\_t* **get\_background\_thread\_count**() const

bool **enumerate\_threads**(*hpx::function*<bool(*thread\_id\_type*)> const &f, *thread\_schedule\_state*  
                          state = *thread\_schedule\_state::unknown*) const

void **abort\_all\_suspended\_threads**() const

bool **cleanup\_terminated**(bool delete\_all) const

*std::size\_t* **get\_os\_thread\_count**() const

Return the number of OS threads running in this thread-manager.

This function will return correct results only if the thread-manager is running.

*std::thread* &**get\_os\_thread\_handle**(*std::size\_t* num\_thread) const

void **report\_error**(*std::size\_t* num\_thread, *std::exception\_ptr* const &e) const

API functions forwarding to notification policy.

This notifies the thread manager that the passed exception has been raised. The exception will be routed through the notifier and the scheduler (which will result in it being passed to the runtime object, which in turn will report it to the console, etc.).

*mask\_type* **get\_used\_processing\_units**() const

Returns the mask identifying all processing units used by this thread manager.

*hwloc\_bitmap\_ptr* **get\_pool\_numa\_bitmap**(*std::string* const &pool\_name) const

void **set\_scheduler\_mode**(*threads::policies::scheduler\_mode* mode,  
                          *hpx::threads::mask\_cref\_type* pu\_mask) const noexcept

void **add\_scheduler\_mode**(*threads::policies::scheduler\_mode* mode,  
                          *hpx::threads::mask\_cref\_type* pu\_mask) const noexcept

struct **async\_execute\_after\_t**

*#include* <timed\_execution\_fwd.hpp> Customization point of asynchronous execution agent creation supporting timed execution.

This asynchronously creates a single function invocation `f()` using the associated executor at the given point in time.

---

**Note:** This calls `exec.async_execute_after(rel_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::async_execute()` on the underlying non-time-scheduled execution agent.

---

#### Param **exec**

[in] The executor object to use for scheduling of the function *f*.

#### Param **rel\_time**

[in] The duration of time after which the given function should be scheduled to run.

#### Param **f**

[in] The function which will be scheduled using the given executor.

**Param ts...**

[in] Additional arguments to use to invoke *f*.

**Return**

*f*(*ts...*)'s result through a future

**Public Functions**

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_duration const

```

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_duration const
                                   &rel_time, F &&f, Ts&&... ts) const
```

struct **async\_execute\_at\_t**

*#include <timed\_execution\_fwd.hpp>* Customization point of asynchronous execution agent creation supporting timed execution.

This asynchronously creates a single function invocation *f*() using the associated executor at the given point in time.

---

**Note:** This calls `exec.async_execute_at(abs_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::async_execute()` on the underlying non-time-scheduled execution agent.

---

**Param exec**

[in] The executor object to use for scheduling of the function *f*.

**Param abs\_time**

[in] The point in time the given function should be scheduled at to run.

**Param f**

[in] The function which will be scheduled using the given executor.

**Param ts...**

[in] Additional arguments to use to invoke *f*.

**Return**

*f*(*ts...*)'s result through a future

**Public Functions**

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_time_point const
                                   &abs_time, F &&f, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_time_point const
                                   &abs_time, F &&f, Ts&&... ts) const
```

struct **post\_after\_t**

*#include <timed\_execution\_fwd.hpp>* Customization point of asynchronous fire & forget execution agent creation supporting timed execution.

This asynchronously (fire & forget) creates a single function invocation  $f()$  using the associated executor at the given point in time.

---

**Note:** This calls `exec.post_after(rel_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::post()` on the underlying non-time-scheduled execution agent.

---

**Param exec**

[in] The executor object to use for scheduling of the function  $f$ .

**Param rel\_time**

[in] The duration of time after which the given function should be scheduled to run.

**Param f**

[in] The function which will be scheduled using the given executor.

**Param ts...**

[in] Additional arguments to use to invoke  $f$ .

## Public Functions

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_duration const
                                   &rel_time, F &&f, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_duration const
                                   &rel_time, F &&f, Ts&&... ts) const
```

struct **post\_at\_t**

*#include <timed\_execution\_fwd.hpp>* Customization point of asynchronous fire & forget execution agent creation supporting timed execution.

This asynchronously (fire & forget) creates a single function invocation  $f()$  using the associated executor at the given point in time.

---

**Note:** This calls `exec.post_at(abs_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::post()` on the underlying non-time-scheduled execution agent.

---

**Param exec**

[in] The executor object to use for scheduling of the function  $f$ .

**Param abs\_time**

[in] The point in time the given function should be scheduled at to run.

**Param f**

[in] The function which will be scheduled using the given executor.

**Param ts...**

[in] Additional arguments to use to invoke  $f$ .

## Public Functions

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_time_point const
                                     &abs_time, F &&f, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_time_point const
                                     &abs_time, F &&f, Ts&&... ts) const
```

struct **sync\_execute\_after\_t**

*#include <timed\_execution\_fwd.hpp>* Customization point of synchronous execution agent creation supporting timed execution.

This synchronously creates a single function invocation *f*() using the associated executor at the given point in time.

---

**Note:** This calls `exec.sync_execute_after(rel_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::sync_execute()` on the underlying non-time-scheduled execution agent.

---

**Param exec**

[in] The executor object to use for scheduling of the function *f*.

**Param rel\_time**

[in] The duration of time after which the given function should be scheduled to run.

**Param f**

[in] The function which will be scheduled using the given executor.

**Param ts...**

[in] Additional arguments to use to invoke *f*.

**Return**

*f*(*ts...*)'s result

## Public Functions

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_duration const
                                     &rel_time, F &&f, Ts&&... ts) const
```

```
template<executor_any Executor, typename F, typename ...Ts>
inline decltype(auto) operator() (Executor &&exec, hpx::chrono::steady_duration const
                                     &rel_time, F &&f, Ts&&... ts) const
```

struct **sync\_execute\_at\_t**

*#include <timed\_execution\_fwd.hpp>* Customization point of synchronous execution agent creation supporting timed execution.

This synchronously creates a single function invocation *f*() using the associated executor at the given point in time.

---

**Note:** This calls `exec.sync_execute_at(abs_time, f, ts...)`, if available, otherwise it emulates timed scheduling by delaying calling `execution::sync_execute()` on the underlying non-time-scheduled

---

execution agent.

---

**Param exec**

## timing

See *Public API* for a list of names and headers that are part of the public HPX API.

### **hpx::chrono::high\_resolution\_clock**

Defined in header [hpx/chrono.hpp](#)<sup>809</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **chrono**

struct **high\_resolution\_clock**

*#include <high\_resolution\_clock.hpp>* Class *hpx::chrono::high\_resolution\_clock* represents the clock with the smallest tick period provided by the implementation. It may be an alias of *std::chrono::system\_clock* or *std::chrono::steady\_clock*, or a third, independent clock. *hpx::chrono::high\_resolution\_clock* meets the requirements of *TrivialClock*.

<sup>809</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/chrono.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/chrono.hpp)

### Public Static Functions

static inline `std::uint64_t now()` noexcept  
returns a `std::chrono::time_point` representing the current value of the clock

static inline constexpr `std::uint64_t() min ()` noexcept

static inline constexpr `std::uint64_t() max ()` noexcept

### `hpx::chrono::high_resolution_timer`

Defined in header `hpx/chrono.hpp`<sup>810</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **chrono**

class **high\_resolution\_timer**

*#include <high\_resolution\_timer.hpp>* *high\_resolution\_timer* is a timer object which measures the elapsed time

### Public Types

enum class **init**

*Values:*

enumerator **no\_init**

### Public Functions

inline **high\_resolution\_timer()** noexcept

inline explicit constexpr **high\_resolution\_timer(init)** noexcept

inline explicit constexpr **high\_resolution\_timer(double t)** noexcept

inline void **restart()** noexcept

restarts the timer

inline double **elapsed()** const noexcept

returns the elapsed time in seconds

inline `std::int64_t elapsed_microseconds()` const noexcept

returns the elapsed time in microseconds

inline `std::int64_t elapsed_nanoseconds()` const noexcept

returns the elapsed time in nanoseconds

---

<sup>810</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include\\_local/include/hpx/chrono.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/core/include_local/include/hpx/chrono.hpp)

### Public Static Functions

```
static inline double now() noexcept
    returns the current time

static inline constexpr double elapsed_max() noexcept
    returns the estimated maximum value for elapsed()

static inline constexpr double elapsed_min() noexcept
    returns the estimated minimum value for elapsed()
```

### Protected Static Functions

```
static inline std::uint64_t take_time_stamp() noexcept
```

### Private Members

```
std::uint64_t start_time_
```

## topology

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/topology/cpu\_mask.hpp

Defined in header `hpx/topology/cpu_mask.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace threads
```

### hpx/topology/topology.hpp

Defined in header `hpx/topology/topology.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace threads
```

## Typedefs

```
using hwloc_bitmap_ptr = std::shared_ptr<hpx_hwloc_bitmap_wrapper>
```

## Enums

```
enum hpx_hwloc_membind_policy
```

Please see hwloc documentation for the corresponding enums HWLOC\_MEMBIND\_XXX.

*Values:*

enumerator **membind\_default**

enumerator **membind\_firsttouch**

enumerator **membind\_bind**

enumerator **membind\_interleave**

enumerator **membind\_replicate**

enumerator **membind\_nexttouch**

enumerator **membind\_mixed**

enumerator **membind\_user**

## Functions

```
topology &create_topology()
```

```
inline topology const &get_topology()
```

Get the global topology instance.

```
inline std::size_t get_memory_page_size()
```

```
struct hpx_hwloc_bitmap_wrapper
```

## Public Functions

**~topology**()

inline *std::size\_t* **get\_socket\_number**(*std::size\_t* num\_thread, [[maybe\_unused]] *error\_code* &ec = *throws*) const noexcept

Return the Socket number of the processing unit the given thread is running on.

### Parameters

- **num\_thread** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline *std::size\_t* **get\_numa\_node\_number**(*std::size\_t* num\_thread, [[maybe\_unused]] *error\_code* &ec = *throws*) const noexcept

Return the NUMA node number of the processing unit the given thread is running on.

### Parameters

- **num\_thread** – [in]

- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline *std::size\_t* **get\_numa\_distance**(*std::size\_t* node\_a, *std::size\_t* node\_b) const noexcept

Return the hardware latency distance between two NUMA nodes. Values are sourced from hwloc's distance matrix when available; otherwise a standard default (10 = local, 20 = remote) is returned.

**Parameters**

- **node\_a** – [in] logical index of the first NUMA node
- **node\_b** – [in] logical index of the second NUMA node

mask\_cref\_type **get\_machine\_affinity\_mask**(*error\_code* &ec = *throws*) const noexcept

Return a bit mask where each set bit corresponds to a processing unit available to the application.

**Parameters**

- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask\_type **get\_service\_affinity\_mask**(mask\_cref\_type used\_processing\_units, *error\_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the service threads in the application.

**Parameters**

- **used\_processing\_units** – [in] This is the mask of processing units which are not available for service threads.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask\_cref\_type **get\_socket\_affinity\_mask**(*std::size\_t* num\_thread, *error\_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the socket it is running on.

**Parameters**

- **num\_thread** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask\_cref\_type **get\_numa\_node\_affinity\_mask**(*std::size\_t* num\_thread, *error\_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the NUMA domain it is running on.

**Parameters**

- **num\_thread** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask\_cref\_type **get\_core\_affinity\_mask**(*std::size\_t* num\_thread, *error\_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the core it is running on.

**Parameters**

- **num\_thread** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask\_cref\_type **get\_thread\_affinity\_mask**(*std::size\_t* num\_thread, *error\_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread.

**Parameters**

- **num\_thread** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **set\_thread\_affinity\_mask**(mask\_cref\_type mask, error\_code &ec = *throws*) const

Use the given bit mask to set the affinity of the given thread. Each set bit corresponds to a processing unit the thread will be allowed to run on.

---

**Note:** Use this function on systems where the affinity must be set from inside the thread itself.

---

**Parameters**

- **mask** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask\_type **get\_thread\_affinity\_mask\_from\_lva**(void const \*lva, error\_code &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit co-located with the memory the given address is currently allocated on.

**Parameters**

- **lva** – [in]
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **print\_affinity\_mask**(std::ostream &os, std::size\_t num\_thread, mask\_cref\_type m, std::string const &pool\_name) const

Prints the given mask *m* to os in a human-readable form.

bool **reduce\_thread\_priority**(error\_code &ec = *throws*) const

Reduce thread priority of the current thread.

**Parameters**

- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::size\_t **get\_number\_of\_sockets**() const

Return the number of available NUMA domains.

std::size\_t **get\_number\_of\_numa\_nodes**() const

Return the number of available NUMA domains.

std::size\_t **get\_number\_of\_cores**() const

Return the number of available cores.

std::size\_t **get\_number\_of\_pus**() const noexcept

Return the number of available hardware processing units.

std::size\_t **get\_number\_of\_numa\_node\_cores**(std::size\_t numa) const

Return number of cores in given numa domain.

std::size\_t **get\_number\_of\_numa\_node\_pus**(std::size\_t numa) const

Return number of processing units in a given numa domain.

std::size\_t **get\_number\_of\_socket\_pus**(std::size\_t socket) const

Return number of processing units in a given socket.

`std::size_t` **get\_number\_of\_core\_pus**(`std::size_t` core) const  
Return number of processing units in given core.

`std::size_t` **get\_number\_of\_socket\_cores**(`std::size_t` socket) const  
Return number of cores units in given socket.

inline `std::size_t` **get\_core\_number**(`std::size_t` num\_thread, *error\_code* &= *throws*) const

`std::size_t` **get\_pu\_number**(`std::size_t` num\_core, `std::size_t` num\_pu, *error\_code* &ec = *throws*) const

`std::size_t` **get\_cache\_size**(*mask\_cref\_type* mask, int level) const  
Return the size of the cache associated with the given mask.

*mask\_type* **get\_cpubind\_mask**(*error\_code* &ec = *throws*) const

*mask\_type* **get\_cpubind\_mask**(`std::thread` &handle, *error\_code* &ec = *throws*) const

*hwloc\_bitmap\_ptr* **cpuset\_to\_nodese**(*mask\_cref\_type* mask) const  
convert a cpu mask into a numa node mask in hwloc bitmap form

void **write\_to\_log**() const

void **\*allocate**(`std::size_t` len) const  
This is equivalent to malloc(), except that it tries to allocate page-aligned memory from the OS.

void **\*allocate\_membind**(`std::size_t` len, *hwloc\_bitmap\_ptr* const &bitmap, *hpx\_hwloc\_membind\_policy* policy, int flags) const  
allocate memory with binding to a numa node set as specified by the policy and flags (see hwloc docs)

*threads::mask\_type* **get\_area\_membind\_nodese**(void const \*addr, `std::size_t` len) const

bool **set\_area\_membind\_nodese**(void const \*addr, `std::size_t` len, void \*nodese) const

int **get\_numa\_domain**(void const \*addr) const

void **deallocate**(void \*addr, `std::size_t` len) const noexcept  
Free memory that was previously allocated by allocate.

void **print\_hwloc**(`std::ostream` &) const

*mask\_type* **init\_socket\_affinity\_mask\_from\_socket**(`std::size_t` num\_socket) const

*mask\_type* **init\_numa\_node\_affinity\_mask\_from\_numa\_node**(`std::size_t` num\_numa\_node) const

*mask\_type* **init\_core\_affinity\_mask\_from\_core**(`std::size_t` num\_core, *mask\_cref\_type* default\_mask = *empty\_mask*) const

*mask\_type* **init\_thread\_affinity\_mask**(`std::size_t` num\_thread) const

*mask\_type* **init\_thread\_affinity\_mask**(`std::size_t` num\_core, `std::size_t` num\_pu) const

*hwloc\_bitmap\_t* **mask\_to\_bitmap**(*mask\_cref\_type* mask, *hwloc\_obj\_type\_t* htype, unsigned \*count = nullptr) const

*mask\_type* **bitmap\_to\_mask**(*hwloc\_bitmap\_t* bitmap, *hwloc\_obj\_type\_t* htype) const

```

struct **lock\_context**

*#include <tracing.hpp>* Context for annotating lock acquisitions and releases.

This struct is used to provide tracing annotations for synchronization primitives such as spinlocks and mutexes. It registers the creation, acquisition, and release of locks to the active tracing backend.

### Public Functions

explicit **lock\_context**(char const \*name = nullptr, void const \*addr = nullptr) noexcept

Constructs a lock context.

#### Parameters

- **name** – The name or description of the lock.
- **addr** – The memory address of the lock, used to track it uniquely.

explicit **lock\_context**(char const \*prefix, char const \*suffix, void const \*addr = nullptr) noexcept

Constructs a lock context with a dynamic name.

#### Parameters

- **prefix** – The prefix for the lock name.
- **suffix** – The suffix for the lock name.
- **addr** – The memory address of the lock, used to track it uniquely.

bool **before\_lock**() const noexcept

Called immediately before attempting to acquire the lock.

#### Returns

true if the prepare event was recorded and `after_lock` should be called.

void **after\_lock**() const noexcept

Called immediately after the lock is successfully acquired.

void **after\_try\_lock**(bool success) const noexcept

Called after a try-lock operation completes.

**Parameters**

**success** – true if the lock was acquired, false if it failed.

void **before\_unlock**() const noexcept

Called immediately before releasing the lock.

void **after\_unlock**() const noexcept

Called immediately after releasing the lock.

### **hpx/util/sed\_transform.hpp**

Defined in header `hpx/util/sed_transform.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

## **Functions**

bool **parse\_sed\_expression**(std::string const &input, std::string &search, std::string &replace)

Parse a sed command.

---

**Note:** Currently, only supports search and replace syntax (s/search/replace/)

---

**Parameters**

- **input** – [in] The content to parse.
- **search** – [out] If the parsing is successful, this string is set to the search expression.
- **replace** – [out] If the parsing is successful, this string is set to the replace expression.

**Returns**

*true* if the parsing was successful, false otherwise.

struct **sed\_transform**

*#include <sed\_transform.hpp>* An unary function object which applies a sed command to its subject and returns the resulting string.

---

**Note:** Currently, only supports search and replace syntax (s/search/replace/)

---

## Public Functions

## hpx/util/insert\_checked.hpp

Defined in header `hpx/util/insert_checked.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **util**

## Functions

template<typename **Iterator**>

constexpr bool **insert\_checked**(*std::pair*<*Iterator*, bool> const &r) noexcept

Helper function for writing predicates that test whether an `std::map` insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy `std::pair<Iterator, bool>` type.

### Parameters

**r** – [in] The return value of a `std::map` insert operation.

### Returns

This function returns **r.second**.

template<typename **Iterator**>

bool **insert\_checked**(*std::pair*<*Iterator*, bool> const &r, *Iterator* &it)

Helper function for writing predicates that test whether an `std::map` insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy `std::pair<Iterator, bool>` type.

### Parameters

- r** – [in] The return value of a `std::map` insert operation.
- r** – [out] A reference to an `Iterator`, which is set to **r.first**.
- it** – [out] on exit, will hold the iterator referring to the inserted element

### Returns

This function returns **r.second**.

### actions

```

### hpx/actions\_base/macros.hpp

Defined in header `hpx/actions_base/macros.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### Defines

**HPX\_REGISTER\_ACTION\_INVOCATION\_COUNT**(Action)

**HPX\_REGISTER\_PER\_ACTION\_DATA\_COUNTER\_TYPES**(Action)

**HPX\_MAKE\_ACTION**(func)

**HPX\_MAKE\_DIRECT\_ACTION**(func)

**HPX\_DECLARE\_ACTION**(...)

Declares an action type.

**HPX\_REGISTER\_ACTION\_DECLARATION**(...)

Declare the necessary component action boilerplate code.

The macro *HPX\_REGISTER\_ACTION\_DECLARATION* can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to declare the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```

namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
    : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }
    }
}

```

(continues on next page)

(continued from previous page)

```
// Component actions need to be declared, this also defines the
// type 'print_greeting_action' representing the action.
HPX_DEFINE_COMPONENT_ACTION(server,
    print_greeting, print_greeting_action);
};
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action)
```

**Example:**

---

**Note:** This macro has to be used once for each of the component actions defined using one of the *HPX\_DEFINE\_COMPONENT\_ACTION* macros. It has to be visible in all translation units using the action, thus it is recommended to place it into the header file defining the component.

---

**HPX\_REGISTER\_ACTION\_DECLARATION(...)****HPX\_REGISTER\_ACTION\_DECLARATION\_1(action)****HPX\_REGISTER\_ACTION(...)**

Define the necessary component action boilerplate code.

The macro *HPX\_REGISTER\_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

---

**Note:** This macro has to be used once for each of the component actions defined using one of the *HPX\_DEFINE\_COMPONENT\_ACTION* or *HPX\_DEFINE\_PLAIN\_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

---

---

**Note:** Only one of the forms of this macro *HPX\_REGISTER\_ACTION* or *HPX\_REGISTER\_ACTION\_ID* should be used for a particular action, never both.

---

**HPX\_REGISTER\_ACTION\_ID(action, actionname, actionid)**

Define the necessary component action boilerplate code and assign a predefined unique id to the action.

The macro *HPX\_REGISTER\_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

The parameter *actionname* specifies a unique name of the action to be used for serialization purposes. The second parameter has to be usable as a plain (nonqualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

The parameter *actionid* specifies a unique integer value which will be used to represent the action during serialization.

---

**Note:** This macro has to be used once for each of the component actions defined using one of the *HPX\_DEFINE\_COMPONENT\_ACTION* or global actions *HPX\_DEFINE\_PLAIN\_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

---

---

**Note:** Only one of the forms of this macro *HPX\_REGISTER\_ACTION* or *HPX\_REGISTER\_ACTION\_ID* should be used for a particular action, never both.

---

### HPX\_DEFINE\_COMPONENT\_ACTION(...)

Registers a member function of a component as an action type with HPX.

The macro *HPX\_DEFINE\_COMPONENT\_ACTION* can be used to register a member function of a component as an action type named *action\_type*.

The parameter *component* is the type of the component exposing the member function *func* which should be associated with the newly defined action type. The parameter *action\_type* is the name of the action type to register with HPX.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
    : public hpx::components::component_base<server>
    {
    public:
        void print_greeting() const
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting,
            print_greeting_action);
    };
}
```

#### Example:

The first argument must provide the type name of the component the action is defined for.

The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending ‘\_action’. The third argument can be omitted only if the second argument with an appended suffix ‘\_action’ resolves to a valid, unqualified C++ type name.

---

**Note:** The macro *HPX\_DEFINE\_COMPONENT\_ACTION* can be used with 2 or 3 arguments. The third argument is optional.

---

#### **HPX\_DEFINE\_PLAIN\_ACTION(...)**

Defines a plain action type.

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // This will define the action type 'app::some_global_action' which
    // represents the function 'app::some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
```

#### **Example:**

---

**Note:** Usually this macro will not be used in user code unless the intent is to avoid defining the action\_type in global namespace. Normally, the use of the macro *HPX\_PLAIN\_ACTION* is recommended.

---

---

**Note:** The macro *HPX\_DEFINE\_PLAIN\_ACTION* can be used with 1 or 2 arguments. The second argument is optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending ‘\_action’. The second argument can be omitted only if the first argument with an appended suffix ‘\_action’ resolves to a valid, unqualified C++ type name.

---

#### **HPX\_DECLARE\_PLAIN\_ACTION(...)**

Declares a plain action type.

#### **HPX\_PLAIN\_ACTION(...)**

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX\_PLAIN\_ACTION* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *name* representing the given function. This macro additionally registers the newly define action type with HPX.

The parameter *func* is a global or free (non-member) function which should be encapsulated into a plain action. The parameter *name* is the name of the action type defined by this macro.

```

namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which
// represents the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action)

```

**Example:**

---

**Note:** The macro `HPX_PLAIN_ACTION` has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

---

---

**Note:** The macro `HPX_PLAIN_ACTION_ID` can be used with 1, 2, or 3 arguments. The second and third arguments are optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending ‘\_action’. The second argument can be omitted only if the first argument with an appended suffix ‘\_action’ resolves to a valid, unqualified C++ type name. The default value for the third argument is `hpx::components::factory_state::check`.

---

---

**Note:** Only one of the forms of this macro `HPX_PLAIN_ACTION` or `HPX_PLAIN_ACTION_ID` should be used for a particular action, never both.

---

**HPX\_PLAIN\_ACTION\_ID(func, name, id)**

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro `HPX_PLAIN_ACTION_ID` can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *actionname* representing the given function.

The parameter *actionid* specifies a unique integer value which will be used to represent the action during serialization.

The parameter *func* is a global or free (non-member) function which should be encapsulated into a plain action. The parameter *name* is the name of the action type defined by this macro.

The second parameter has to be usable as a plain (nonqualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘.’.

```

namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which
// represents the function 'app::some_global_function'.

```

(continues on next page)

(continued from previous page)

```
HPX_PLAIN_ACTION_ID(app::some_global_function, some_global_action,  
    some_unique_id);
```

**Example:**

---

**Note:** The macro *HPX\_PLAIN\_ACTION\_ID* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

---

---

**Note:** Only one of the forms of this macro *HPX\_PLAIN\_ACTION* or *HPX\_PLAIN\_ACTION\_ID* should be used for a particular action, never both.

                      std::uint32_t num_threads, error_code &ec = throws)
    Add a locality to the runtime.

parcelset::endpoints_type const &resolve_locality(naming::gid_type const &gid, error_code
                                                &ec = throws)
    Resolve a locality to its prefix.
Returns
    Returns an empty vector if the locality is not registered.

bool has_resolved_locality(naming::gid_type const &gid)

bool unregister_locality(naming::gid_type const &gid, error_code &ec = throws)
    Remove a locality from the runtime.

void remove_resolved_locality(naming::gid_type const &gid)
    remove given locality from locality cache

bool get_console_locality(naming::gid_type &locality, error_code &ec = throws)
    Get locality locality_id of the console locality.
```

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters**

- **locality** – [out] The locality\_id value uniquely identifying the console locality. This is valid only, if the return value of this function is true.
- **try\_cache** – [in] If this is set to true the console is first tried to be found in the local cache. Otherwise this function will always query AGAS, even if the console locality\_id is already known locally.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function returns *true* if a console locality\_id exists and returns *false* otherwise.

```
bool get_localities(std::vector<naming::gid_type> &locality_ids,
                    components::component_type type, error_code &ec = throws) const
```

Query for the locality\_ids of all known localities.

This function returns the locality\_ids of all localities known to the AGAS server or all localities having a registered factory for a given component type.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **locality\_ids** – [out] The vector will contain the prefixes of all localities registered with the AGAS server. The returned vector holds the prefixes representing the runtime\_support components of these localities.
- **type** – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component\_enum\_type::invalid*, which will return prefixes of all localities.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
inline bool get_localities(std::vector<naming::gid_type> &locality_ids, error_code &ec =
                           throws) const
```

```
hpx::future<std::uint32_t> get_num_localities_async(components::component_type type =
                                                    to_int(hpx::components::component_enum_type::invalid))
                                                    const
```

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **type** – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component\_type::invalid*, which will return prefixes of all localities.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

```
std::uint32_t get_num_localities(components::component_type type, error_code &ec = throws)
                                const
```

```
inline std::uint32_t get_num_localities(error_code &ec = throws) const  
  
hpx::future<std::uint32_t> get_num_overall_threads_async() const  
  
std::uint32_t get_num_overall_threads(error_code &ec = throws) const  
  
hpx::future<std::vector<std::uint32_t>> get_num_threads_async() const  
  
std::vector<std::uint32_t> get_num_threads(error_code &ec = throws) const  
  
components::component_type get_component_id(std::string const &name, error_code &ec =  
                                              throws) const
```

Return a unique id usable as a component type.

This function returns the component type id associated with the given component name. If this is the first request for this component name a new unique id will be created.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **name** – [in] The component name (string) to get the component type for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

The function returns the currently associated component type. Any error results in an exception thrown from this function.

```
void iterate_types(iterate_types_function_type const &f, error_code &ec = throws) const  
  
std::string get_component_type_name(components::component_type id, error_code &ec =  
                                     throws) const  
  
inline components::component_type register_factory(naming::gid_type const &locality_id,  
                                                    std::string const &name, error_code &ec  
                                                    = throws) const
```

Register a factory for a specific component type.

This function allows to register a component factory for a given locality and component type.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **locality\_id** – [in] The locality value uniquely identifying the given locality the factory needs to be registered for.
- **name** – [in] The component name (string) to register a factory for the given component type for.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

The function returns the currently associated component type. Any error results in an exception thrown from this function. The returned component type is the same as if the function *get\_component\_id* was called using the same component name.

---

```
components::component_type register_factory(std::uint32_t locality_id, std::string const
&name, error_code &ec = throws) const
```

```
bool get_id_range(std::uint64_t count, naming::gid_type &lower_bound, naming::gid_type
&upper_bound, error_code &ec = throws)
```

Get unique range of freely assignable global ids.

Every locality needs to be able to assign global ids to different components without having to consult the AGAS server for every id to generate. This function can be called to preallocate a range of ids usable for this purpose.

---

**Note:** This function assigns a range of global ids usable by the given locality for newly created components. Any of the returned global ids still has to be bound to a local address, either by calling *bind* or *bind\_range*.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **l** – [in] The locality the locality id needs to be generated for. Repeating calls using the same locality results in identical *locality\_id* values.
- **count** – [in] The number of global ids to be generated.
- **lower\_bound** – [out] The lower bound of the assigned id range. The returned value can be used as the first id to assign. This is valid only, if the return value of this function is true.
- **upper\_bound** – [out] The upper bound of the assigned id range. The returned value can be used as the last id to assign. This is valid only, if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

```
inline bool bind_local(naming::gid_type const &id, naming::address const &addr, error_code
&ec = throws)
```

Bind a global address to a local address.

Every element in the HPX namespace has a unique global address (global id). This global address has to be associated with a concrete local address to be able to address an instance of a component using its global address.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** Binding a gid to a local address sets its global reference count to one.

---

#### Parameters

- **id** – [in] The global address which has to be bound to the local address.

- **addr** – [in] The local address to be bound to the global address.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function returns *true*, if this global id got associated with an local address. It returns *false* otherwise.

```
inline hpx::future<bool> bind_async(naming::gid_type const &id, naming::address const &addr,  
                                   std::uint32_t locality_id)
```

```
inline hpx::future<bool> bind_async(naming::gid_type const &id, naming::address const &addr,  
                                   naming::gid_type const &locality)
```

```
bool bind_range_local(naming::gid_type const &lower_id, std::uint64_t count, naming::address  
                     const &baseaddr, std::uint64_t offset, error_code &ec = throws)
```

Bind unique range of global ids to given base address.

Every locality needs to be able to bind global ids to different components without having to consult the AGAS server for every id to bind. This function can be called to bind a range of consecutive global ids to a range of consecutive local addresses (separated by a given *offset*).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** Binding a gid to a local address sets its global reference count to one.

---

**Parameters**

- **lower\_id** – [in] The lower bound of the assigned id range. The value can be used as the first id to assign.
- **count** – [in] The number of consecutive global ids to bind starting at *lower\_id*.
- **baseaddr** – [in] The local address to bind to the global id given by *lower\_id*. This is the base address for all additional local addresses to bind to the remaining global ids.
- **offset** – [in] The offset to use to calculate the local addresses to be bound to the range of global ids.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function returns *true*, if the given range was successfully bound. It returns *false* otherwise.

```
hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t count,  
                                   naming::address const &baseaddr, std::uint64_t offset,  
                                   naming::gid_type const &locality)
```

```
inline hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t  
                                         count, naming::address const &baseaddr,  
                                         std::uint64_t offset, std::uint32_t locality_id)
```

```
inline bool unbind_local(naming::gid_type const &id, error_code &ec = throws)
```

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

---

**Note:** You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind\_range*.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!

---

#### Parameters

- **id** – [in] The global address (id) for which the association has to be removed.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

```
inline bool unbind_local(naming::gid_type const &id, naming::address &addr, error_code &ec =
    throws)
```

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

---

**Note:** You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind\_range*.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!

---

#### Parameters

- **id** – [in] The global address (id) for which the association has to be removed.
- **addr** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

```
inline bool unbind_range_local(naming::gid_type const &lower_id, std::uint64_t count,
    error_code &ec = throws)
```

Unbind the given range of global ids.

---

**Note:** You can unbind only global ids bound using the function *bind\_range*. Do not use this function to unbind any of the global ids bound using *bind*.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!

---

#### Parameters

- **lower\_id** – [in] The lower bound of the assigned id range. The value must be the first id of the range as specified to the corresponding call to *bind\_range*.
- **count** – [in] The number of consecutive global ids to unbind starting at *lower\_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind\_range*.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

```
bool unbind_range_local(naming::gid_type const &lower_id, std::uint64_t count,  
                        naming::address &addr, error_code &ec = throws)
```

Unbind the given range of global ids.

---

**Note:** You can unbind only global ids bound using the function *bind\_range*. Do not use this function to unbind any of the global ids bound using *bind*.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** This function will raise an error if the global reference count of the given gid is not zero!

---

#### Parameters

- **lower\_id** – [in] The lower bound of the assigned id range. The value must be the first id of the range as specified to the corresponding call to *bind\_range*.
- **count** – [in] The number of consecutive global ids to unbind starting at *lower\_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind\_range*.
- **addr** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns *true* if a new range has been generated (it has been called for the first

time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call.

```
hpx::future<naming::address> unbind_range_async(naming::gid_type const &lower_id,
                                                std::uint64_t count = 1)
```

```
inline bool is_local_address_cached(naming::gid_type const &id, error_code &ec = throws)
```

Test whether the given address refers to a local object.

This function will test whether the given address refers to an object living on the locality of the caller.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The address to test.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns *true* if the passed address refers to an object which lives on the locality of the caller.

```
bool is_local_address_cached(naming::gid_type const &id, naming::address &addr,
                             error_code &ec = throws)
```

```
bool is_local_address_cached(naming::gid_type const &id, naming::address &addr,
                             std::pair<bool, components::pinned_ptr> &r,
                             hpx::move_only_function<std::pair<bool,
                             components::pinned_ptr>(naming::address const&)> &&f,
                             error_code &ec = throws)
```

```
bool is_local_lva_encoded_address(std::uint64_t msb) const
```

```
inline bool resolve_local(naming::gid_type const &id, naming::address &addr, error_code &ec
                           = throws)
```

Resolve a given global address (*id*) to its associated local address.

This function returns the local address which is currently associated with the given global address (*id*).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **id** – [in] The global address (*id*) for which the associated local address should be returned.
- **addr** – [out] The local address which currently is associated with the given global address (*id*), this is valid only if the return value of this function is true.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function returns *true* if the global address has been resolved successfully (there exists an association to a local address) and the associated local address has been returned. The

function returns *false* if no association exists for the given global address. Any error results in an exception thrown from this function.

```
inline bool resolve_local(hpx::id_type const &id, naming::address &addr, error_code &ec =
    throws)

inline naming::address resolve_local(naming::gid_type const &id, error_code &ec = throws)

inline naming::address resolve_local(hpx::id_type const &id, error_code &ec = throws)

hpx::future_or_value<naming::address> resolve_async(naming::gid_type const &id)

inline hpx::future_or_value<naming::address> resolve_async(hpx::id_type const &id)

hpx::future_or_value<id_type> get_colocation_id_async(hpx::id_type const &id)

bool resolve_full_local(naming::gid_type const &id, naming::address &addr, error_code &ec
    = throws)

inline bool resolve_full_local(hpx::id_type const &id, naming::address &addr, error_code &ec
    = throws)

inline naming::address resolve_full_local(naming::gid_type const &id, error_code &ec =
    throws)

inline naming::address resolve_full_local(hpx::id_type const &id, error_code &ec = throws)

hpx::future_or_value<naming::address> resolve_full_async(naming::gid_type const &id)

inline hpx::future_or_value<naming::address> resolve_full_async(hpx::id_type const &id)

bool resolve_cached(naming::gid_type const &id, naming::address &addr, error_code &ec =
    throws)

inline bool resolve_cached(hpx::id_type const &id, naming::address &addr, error_code &ec =
    throws)

inline bool resolve_local(naming::gid_type const *gids, naming::address *addrs, std::size_t size,
    hpx::detail::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve_full_local(naming::gid_type const *gids, naming::address *addrs, std::size_t size,
    hpx::detail::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve_cached(naming::gid_type const *gids, naming::address *addrs, std::size_t size,
    hpx::detail::dynamic_bitset<> &locals, error_code &ec = throws)

hpx::future_or_value<std::int64_t> incref_async(naming::gid_type const &gid, std::int64_t
    credits = 1, hpx::id_type const &keep_alive =
    hpx::invalid_id)
```

Increment the global reference count for the given id.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **gid** – [in] The global address (id) for which the global reference count has to be incremented.

- **credits** – [in] The number of reference counts to add for the given id.
- **keep\_alive** – [in] Id to keep alive (if valid)
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

Whether the operation was successful.

```
inline std::int64_t incref(naming::gid_type const &gid, std::int64_t credits = 1, error_code &ec =
    throws)
```

```
void decref(naming::gid_type const &id, std::int64_t credits = 1, error_code &ec = throws)
```

Decrement the global reference count for the given id.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters**

- **id** – [in] The global address (id) for which the global reference count has to be decremented.
- **t** – [out] If this was the last outstanding global reference for the given gid (the return value of this function is zero), *t* will be set to the component type of the corresponding element. Otherwise *t* will not be modified.
- **credits** – [in] The number of reference counts to add for the given id.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

The global reference count after the decrement.

```
hpx::future<iterate_names_return_type> iterate_ids(std::string const &pattern) const
```

Invoke the supplied *hpx::function* for every registered global name.

This function iterates over all registered global ids and returns every found entry matching the given name pattern. Any error results in an exception thrown (or reported) from this function.

**Parameters**

**pattern** – [in] pattern (possibly using wildcards) to match all existing entries against

```
bool register_name(std::string const &name, naming::gid_type const &id, error_code &ec =
    throws) const
```

Register a global name with a global address (id)

This function registers an association between a global name (string) and a global address (id) usable with one of the functions above (bind, unbind, and resolve).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

**Parameters**

- **name** – [in] The global name (string) to be associated with the global address.
- **id** – [in] The global address (id) to be associated with the global address.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

The function returns *true* if the global name was registered. It returns false if the global name is not registered.

*hpx::future<bool>* **register\_name\_async**(*std::string* const &name, *hpx::id\_type* const &id) const  
*bool* **register\_name**(*std::string* const &name, *hpx::id\_type* const &id, *error\_code* &ec = *throws*) const

*hpx::future<hpx::id\_type>* **unregister\_name\_async**(*std::string* const &name) const

Unregister a global name (release any existing association)

This function releases any existing association of the given global name with a global address (id).

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **name** – [in] The global name (string) for which any association with a global address (id) has to be released.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

The function returns *true* if an association of this global name has been released, and it returns *false*, if no association existed. Any error results in an exception thrown from this function.

*hpx::id\_type* **unregister\_name**(*std::string* const &name, *error\_code* &ec = *throws*) const

*hpx::future<hpx::id\_type>* **resolve\_name\_async**(*std::string* const &name) const

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

This function returns true if it returned global address (id), which is currently associated with the given global name, and it returns false, if currently there is no association for this global name. Any error results in an exception thrown from this function.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **name** – [in] The global name (string) for which the currently associated global address has to be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

[out] The id currently associated with the given global name (valid only if the return value is true).

*hpx::id\_type* **resolve\_name**(*std::string* const &name, *error\_code* &ec = *throws*) const

*future<hpx::id\_type>* **on\_symbol\_namespace\_event**(*std::string* const &name, bool  
call\_for\_past\_events = false) const

Install a listener for a given symbol namespace event.

This function installs a listener for a given symbol namespace event. It returns a future which becomes ready as a result of the listener being triggered.

---

**Note:** The only event type which is currently supported is *symbol\_ns\_bind*, i.e. the listener is triggered whenever a global id is registered with the given name.

---

#### Parameters

- **name** – [in] The global name (string) for which the given event should be triggered.
- **evt** – [in] The event for which a listener should be installed.
- **call\_for\_past\_events** – [in, optional] Trigger the listener even if the given event has already happened in the past. The default for this parameter is *false*.

#### Returns

A future instance encapsulating the global id which is causing the registered listener to be triggered.

```
void update_cache_entry(naming::gid_type const &gid, gva const &gva, error_code &ec =
                        throws)
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
inline void update_cache_entry(naming::gid_type const &gid, naming::address const &addr,
                               std::uint64_t count = 0, std::uint64_t offset = 0, error_code &ec
                               = throws)
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
bool get_cache_entry(naming::gid_type const &gid, gva &gva, naming::gid_type &idbase,
                     error_code &ec = throws) const
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
void remove_cache_entry(naming::gid_type const &id, error_code &ec = throws) const
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
void clear_cache(error_code &ec = throws) const
```

**Warning:** This function is for internal use only. It is dangerous and may break your code if you use it.

```
void start_shutdown(error_code &ec = throws)
```

*hpx::future<std::pair<hpx::id\_type, naming::address>>* **begin\_migration**(*hpx::id\_type* const &id)

start/stop migration of an object

**Returns**

Current locality and address of the object to migrate

bool **end\_migration**(*hpx::id\_type* const &id)

*std::pair<bool, components::pinned\_ptr>* **was\_object\_migrated**(*naming::gid\_type* const &gid,  
*hpx::move\_only\_function<components::pinned\_ptr>*  
&&f)

Maintain list of migrated objects.

*hpx::future<void>* **mark\_as\_migrated**(*naming::gid\_type* const &gid,  
*hpx::move\_only\_function<std::pair<bool,*  
*hpx::future<void>>()>* &&f, bool  
expect\_to\_be\_marked\_as\_migrating)

Mark the given object as being migrated (if the object is unpinned). Delay migration until the object is unpinned otherwise.

void **unmark\_as\_migrated**(*naming::gid\_type* const &gid, *hpx::move\_only\_function<void()>*  
&&f)

Remove the given object from the table of migrated objects.

void **pre\_cache\_endpoints**(*std::vector<parcelset::endpoints\_type>* const&)

*hpx::id\_type* **bootstrap\_primary\_namespace\_id()**

### namespace **server**

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

|                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                         |

| prefix                                                                                                  | - Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.                                                                                                                                                                                                                                                                            |
| RC                                                                                                      | - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID.<br>Bit 93 is used by the locking scheme for <i>gid_types</i> .<br>Bit 94 is a flag which is set if the credit value is valid.<br>Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality).                                                       |
| identifier                                                                                              | - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For <code>\a hpx#components#component_enum_type#runtime_support</code> the high 24 bits are zeroed and the low 64 bits hold the LVA of the component. |

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```

00000000xxxxxxxxxxxxxxxxxxxxxxxxxxxx
    Historically unused address space reserved for future use.
xxxxxxxxxxx0000xxxxxxxxxxxxxxxxxxxx
    Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxxxxxx
    Prefix of the bootstrap AGAS locality.
00000001000000010000000000000001
    Address of the primary_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000002

```

(continues on next page)

(continued from previous page)

```
    Address of the component_namespace component on the bootstrap AGAS
    locality.
0000000010000000010000000000000003
    Address of the symbol_namespace component on the bootstrap AGAS
    locality.
0000000010000000010000000000000004
    Address of the locality_namespace component on the bootstrap AGAS
    locality.
```

---

**Note:** The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

---

## hpx::get\_colocation\_id

Defined in header `hpx/runtime.hpp`<sup>811</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

*hpx::id\_type* **get\_colocation\_id**(*launch::sync\_policy*, *hpx::id\_type* const &id, *error\_code* &ec = *throws*)

Return the id of the locality where the object referenced by the given id is currently located on.

The function *hpx::get\_colocation\_id()* returns the id of the locality where the given object is currently located.

### See also:

*hpx::get\_colocation\_id()*

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

## Parameters

- **id** – [in] The id of the object to locate.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

---

<sup>811</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/runtime.hpp>

```
hpx::future<hpx::id_type> get_colocation_id(hpx::id_type const &id)
```

Asynchronously return the id of the locality where the object referenced by the given id is currently located on.

**See also:**

```
hpx::get_colocation_id(launch::sync_policy)
```

**Parameters**

**id** – [in] The id of the object to locate.

## async\_distributed

See *Public API* for a list of names and headers that are part of the public HPX API.

### hpx/async\_distributed/packaged\_action.hpp

Defined in header `hpx/async_distributed/packaged_action.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **lcos**

```
template<typename Action, typename Result, bool DirectExecute>
```

```
class packaged_action
```

*#include <packaged\_action.hpp>* A *packaged\_action* can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the *packaged\_action* using the LCO's *set\_event* action

A *packaged\_action* is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on an eager evaluated remote operation returning a result of the type *Result*.

---

**Note:** The action executed using the *packaged\_action* as a continuation must return a value of a type convertible to the type as specified by the template parameter *Result*.

---

#### Template Parameters

- **Action** – The template parameter *Action* defines the action to be executed by this *packaged\_action* instance. The arguments *arg0*,... *argN* are used as parameters for this action.
- **Result** – The template parameter *Result* defines the type this *packaged\_action* is expected to return from its associated future *packaged\_action::get\_future*.
- **DirectExecute** – The template parameter *DirectExecute* is an optimization aid allowing to execute the action directly if the target is local (without spawning a new thread for this). This template does not have to be supplied explicitly as it is derived from the template parameter *Action*.

```
template<typename Action, typename Result>
```

```
class packaged_action<Action, Result, false> : public hpx::distributed::promise<Result,
hpx::traits::extract_action<Action>::remote_result_type>
```

Subclassed by *hpx::lcos::packaged\_action*< Action, Result, true >

## Public Functions

```
inline packaged_action()
```

```
template<typename Allocator>
```

```
inline packaged_action(std::allocator_arg_t, Allocator const &alloc)
```

```
template<typename ...Ts>
```

```
inline void post(hpx::id_type const &id, Ts&&... vs)
```

```
template<typename ...Ts>
```

```
inline void post(naming::address &&addr, hpx::id_type const &id, Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>
```

```
inline void post_cb(hpx::id_type const &id, Callback &&cb, Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>
```

```
inline void post_cb(naming::address &&addr, hpx::id_type const &id, Callback &&cb, Ts&&...
vs)
```

```
template<typename ...Ts>
```

```
inline void post_p(hpx::id_type const &id, hpx::launch policy, Ts&&... vs)
```

```
template<typename ...Ts>
```

```
inline void post_p(naming::address &&addr, hpx::id_type const &id, hpx::launch policy, Ts&&...
vs)
```

```

```

```
inline void post_p_cb(hpx::id_type const &id, hpx::launch policy, Callback &&cb, Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>
```

```
inline void post_p_cb(naming::address &&addr, hpx::id_type const &id, hpx::launch policy,
Callback &&cb, Ts&&... vs)
```

```
template<typename ...Ts>
```

```
inline void post_deferred(naming::address &&addr, hpx::id_type const &id, hpx::launch policy,
Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>
```

```
inline void post_deferred_cb(naming::address &&addr, hpx::id_type const &id, hpx::launch
policy, Callback &&cb, Ts&&... vs)
```

## Protected Types

```
using action_type = hpx::traits::extract_action<Action>::type
```

```
using remote_result_type = action_type::remote_result_type
```

```
using base_type = hpx::distributed::promise<Result, remote_result_type>
```

## Protected Functions

```
template<typename ...Ts>  
inline void do_post(naming::address &&addr, hpx::id_type const &id, hpx::launch policy, Ts&&...  
vs)
```

```
template<typename ...Ts>  
inline void do_post(hpx::id_type const &id, hpx::launch policy, Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>  
inline void do_post_cb(naming::address &&addr, hpx::id_type const &id, hpx::launch policy,  
Callback &&cb, Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>  
inline void do_post_cb(hpx::id_type const &id, hpx::launch policy, Callback &&cb, Ts&&... vs)
```

```
template<typename Action, typename Result>
```

```
class packaged_action<Action, Result, true> : public hpx::lcos::packaged_action<Action, Result,  
false>
```

## Public Functions

```
inline packaged_action()
```

Construct a (non-functional) instance of a `packaged_action`. To use this instance its member function `post` needs to be directly called.

```
template<typename Allocator>  
inline packaged_action(std::allocator_arg_t, Allocator const &alloc)
```

```
template<typename ...Ts>  
inline void post(hpx::id_type const &id, Ts&&... vs)
```

```
template<typename ...Ts>  
inline void post(naming::address &&addr, hpx::id_type const &id, Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>  
inline void post_cb(hpx::id_type const &id, Callback &&cb, Ts&&... vs)
```

```
template<typename Callback, typename ...Ts>  
inline void post_cb(naming::address &&addr, hpx::id_type const &id, Callback &&cb, Ts&&...  
vs)
```

## Private Types

using **action\_type** = *packaged\_action*<*Action*, *Result*, false>::action\_type

### hpx/async\_distributed/trigger\_lco.hpp

Defined in header `hpx/async_distributed/trigger_lco.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### hpx/async\_distributed/base\_lco\_with\_value.hpp

Defined in header `hpx/async_distributed/base_lco_with_value.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

namespace **lcos**

template<typename **Result**, typename **RemoteResult**, typename **ComponentTag**>

class **base\_lco\_with\_value** : public *hpx::lcos::base\_lco*, public *ComponentTag*

*#include* <*base\_lco\_with\_value.hpp*> The *base\_lco\_with\_value* class is the common base class for all LCO's synchronizing on a value. The *RemoteResult* template argument should be set to the type of the argument expected for the *set\_value* action.

#### Template Parameters

- **RemoteResult** – The type of the result value to be carried back to the LCO instance.
- **ComponentTag** – The tag type representing the type of the component (either *component\_tag* or *managed\_component\_tag*).

## Public Types

using **wrapping\_type** = detail::base\_lco\_wrapping\_type<*ComponentTag*, *base\_lco\_with\_value*>::type

using **base\_type\_holder** = *base\_lco\_with\_value*

## Public Functions

inline void **set\_value\_nonvirt**(*RemoteResult* &&result)

The *function* `set_value_nonvirt` is called whenever a *set\_value\_action* is applied on this LCO instance. This function just forwards to the virtual function *set\_value*, which is overloaded by the derived concrete LCO.

### Parameters

**result** – [in] The result value to be transferred from the remote operation back to this LCO instance.

inline *Result* **get\_value\_nonvirt**()

The *function* `get_result_nonvirt` is called whenever a *get\_result\_action* is applied on this LCO instance. This function just forwards to the virtual function *get\_result*, which is overloaded by the derived concrete LCO.

**HPX\_DEFINE\_COMPONENT\_DIRECT\_ACTION** (*base\_lco\_with\_value*, *set\_value\_nonvirt*, *set\_value\_action*) **HPX\_DEFINE\_COMPONENT\_DIRECT\_ACTION**(*base\_lco\_with\_value*

The *set\_value\_action* may be used to trigger any LCO instances while carrying an additional parameter of any type.

*RemoteResult* is taken by rvalue ref. This allows for perfect forwarding. When the action thread function is created, the values are moved into the called function. If we took it by const lvalue reference, we would disable the possibility to further move the result to the designated destination.

### Parameters

**RemoteResult** – [in] The type of the result to be transferred back to this LCO instance.

The *get\_value\_action* may be used to query the value this LCO instance exposes as its ‘result’ value.

## Public Members

**get\_value\_nonvirt**

## Public Static Functions

static inline *components::component\_type* **get\_component\_type**() noexcept

static inline void **set\_component\_type**(*components::component\_type* type)

## Protected Types

using **result\_type** = *std::conditional\_t*<*std::is\_void\_v*<*Result*>, *util::unused\_type*, *Result*>

### Protected Functions

**~base\_lco\_with\_value()** override = default

Destructor, needs to be virtual to allow for clean destruction of derived objects

inline virtual void **set\_event()** override

virtual void **set\_value**(*RemoteResult* &&result) = 0

virtual *result\_type* **get\_value()** = 0

inline virtual *result\_type* **get\_value**(*error\_code*&)

template<typename **ComponentTag**>

class **base\_lco\_with\_value**<void, void, *ComponentTag*> : public *hpx::lcos::base\_lco*, public *ComponentTag*

*#include <base\_lco\_with\_value.hpp>* The *base\_lco*<void> specialization is used whenever the *set\_event* action for a particular LCO doesn't carry any argument.

#### Template Parameters

**void** – This specialization expects no result value and is almost completely equivalent to the plain *base\_lco*.

### Public Types

using **wrapping\_type** = detail::base\_lco\_wrapping\_type<*ComponentTag*, *base\_lco\_with\_value*>::type

using **base\_type\_holder** = *base\_lco\_with\_value*

using **set\_value\_action** = *base\_lco*::set\_event\_action

Destructor, needs to be virtual to allow for clean destruction of derived objects

namespace **traits**

## hpx/async\_distributed/trigger\_lco\_fwd.hpp

Defined in header `hpx/async_distributed/trigger_lco_fwd.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

void **trigger\_lco\_event**(*hpx::id\_type* id, *naming::address* &&addr, bool move\_credits = true)

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **trigger\_lco\_event**(*hpx::id\_type* const &id, bool move\_credits = true)

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **trigger\_lco\_event**(*hpx::id\_type* id, *naming::address* &&addr, *hpx::id\_type* const &cont, bool move\_credits = true)

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **trigger\_lco\_event**(*hpx::id\_type* const &id, *hpx::id\_type* const &cont, bool move\_credits = true)

Trigger the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set\_lco\_value**(hpx::id\_type id, naming::address &&addr, Result &&t, bool move\_credits = true)

Set the result value for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set\_lco\_value**(hpx::id\_type const &id, Result &&t, bool move\_credits = true)

Set the result value for the (managed) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set\_lco\_value\_unmanaged**(hpx::id\_type const &id, Result &&t, bool move\_credits = true)

Set the result value for the (unmanaged) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set\_lco\_value**(hpx::id\_type id, naming::address &&addr, Result &&t, hpx::id\_type const &cont, bool move\_credits = true)

Set the result value for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>

void **set\_lco\_value**(hpx::id\_type const &id, Result &&t, hpx::id\_type const &cont, bool move\_credits = true)

Set the result value for the (managed) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
template<typename Result>  
void set_lco_value_unmanaged(hpx::id_type const &id, Result &&t, hpx::id_type const &cont, bool  
    move_credits = true)
```

Set the result value for the (unmanaged) LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
void set_lco_error(hpx::id_type id, naming::address &&addr, std::exception_ptr const &e, bool  
    move_credits = true)
```

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
void set_lco_error(hpx::id_type id, naming::address &&addr, std::exception_ptr &&e, bool move_credits  
    = true)
```

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

```
inline void set_lco_error(hpx::id_type const &id, std::exception_ptr const &e, bool move_credits = true)
```

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **set\_lco\_error**(hpx::id\_type const &id, std::exception\_ptr &&e, bool move\_credits = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set\_lco\_error**(hpx::id\_type id, naming::address &&addr, std::exception\_ptr const &e, hpx::id\_type const &cont, bool move\_credits = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **set\_lco\_error**(hpx::id\_type id, naming::address &&addr, std::exception\_ptr &&e, hpx::id\_type const &cont, bool move\_credits = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **set\_lco\_error**(hpx::id\_type const &id, std::exception\_ptr const &e, hpx::id\_type const &cont, bool move\_credits = true)

Set the error state for the LCO referenced by the given id.

#### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **set\_lco\_error**(hpx::id\_type const &id, std::exception\_ptr &&e, hpx::id\_type const &cont, bool move\_credits = true)

Set the error state for the LCO referenced by the given id.

### Parameters

- **id** – [in] This represents the id of the LCO which should receive the error value.
- **e** – [in] This is the error value which should be sent to the LCO.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move\_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

## hpx::sync (distributed)

Defined in header `hpx/async.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

```
template<typename Action, typename Target, typename ...Ts>  
decltype(auto) sync(Action &&action, Target &&target, Ts&&... ts)
```

The distributed implementation of `hpx::sync` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID. The action executes synchronously.

### Template Parameters

- **Action** – The type of action instance
- **Target** – The type of target where the action should be executed
- **Ts** – The type of any additional arguments

### Parameters

- **action** – The action instance to be executed
- **target** – The target where the action should be executed
- **ts** – Additional arguments

### Returns

`hpx::future` referring to the shared state created by this call to `hpx::sync`

## hpx/async\_distributed/base\_lco.hpp

Defined in header `hpx/async_distributed/base_lco.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
template<>
```

```
struct get_lva<hpx::lcos::base_lco>
```

### Public Static Functions

```
static inline constexpr hpx::lcos::base_lco *call(hpx::naming::address_type lva) noexcept
template<>
struct get_lva<hpx::lcos::base_lco const>
```

### Public Static Functions

template<> base_lco const >
```

### Public Static Functions

```
static inline constexpr hpx::lcos::base_lco const *call(hpx::naming::address_type lva) noexcept

namespace lcos
```

```
class base_lco
```

*#include <base\_lco.hpp>* The *base\_lco* class is the common base class for all LCO's implementing a simple *set\_event* action

Subclassed by *hpx::lcos::base\_lco\_with\_value< Result, RemoteResult, ComponentTag >*, *hpx::lcos::base\_lco\_with\_value< void, void, ComponentTag >*

### Public Types

```
typedef components::managed_component<base_lco> wrapping_type
```

```
typedef base_lco base_type_holder
```

## Public Functions

virtual void **set\_event**() = 0

virtual void **set\_exception**(std::exception\_ptr const &e)

virtual void **connect**(hpx::id\_type const&)

virtual void **disconnect**(hpx::id\_type const&)

virtual **~base\_lco**()

Destructor, needs to be virtual to allow for clean destruction of derived objects

void **set\_event\_nonvirt**()

The *function* `set_event_nonvirt` is called whenever a *set\_event\_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set\_event*, which is overloaded by the derived concrete LCO.

void **set\_exception\_nonvirt**(std::exception\_ptr const &e)

The *function* `set_exception` is called whenever a *set\_exception\_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set\_exception*, which is overloaded by the derived concrete LCO.

### Parameters

**e** – [in] The exception encapsulating the error to report to this LCO instance.

void **connect\_nonvirt**(hpx::id\_type const &id)

The *function* `connect_nonvirt` is called whenever a *connect\_action* is applied on a instance of a LCO. This function just forwards to the virtual function *connect*, which is overloaded by the derived concrete LCO.

### Parameters

**id** – [in] target id

void **disconnect\_nonvirt**(hpx::id\_type const &id)

The *function* `disconnect_nonvirt` is called whenever a *disconnect\_action* is applied on a instance of a LCO. This function just forwards to the virtual function *disconnect*, which is overloaded by the derived concrete LCO.

### Parameters

**id** – [in] target id

**HPX\_DEFINE\_COMPONENT\_DIRECT\_ACTION (base\_lco, set\_event\_nonvirt, set\_event\_action) HPX\_DEFINE\_COMPONENT\_DIRECT\_ACTION(base\_lco**

Each of the exposed functions needs to be encapsulated into an action type, allowing to generate all required boilerplate code for threads, serialization, etc.

The *set\_event\_action* may be used to unconditionally trigger any LCO instances, it carries no additional parameters. The *set\_exception\_action* may be used to transfer arbitrary error information from the remote site to the LCO instance specified as a continuation. This action carries 2 parameters:

### Parameters

**std::exception\_ptr** – [in] The exception encapsulating the error to report to this LCO instance.

**set\_exception\_action HPX\_DEFINE\_COMPONENT\_DIRECT\_ACTION (base\_lco, connect\_nonvirt, connect\_action) HPX\_DEFINE\_COMPONENT\_DIRECT\_ACTION(base\_lco**

The *connect\_action* may be used to.

The `set_exception_action` may be used to

## Public Members

## Public Static Functions

static `components::component_type` `get_component_type()` noexcept

static void `set_component_type(components::component_type type)`

## `hpx::distributed::promise`

Defined in header `hpx/future.hpp`<sup>812</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace `hpx`

namespace `distributed`

template<typename `Result`, typename `RemoteResult`>

class `promise`

*#include <promise.hpp>* A promise can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the promise using the LCO's `set_event` action

A promise is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*. The *promise* allows to synchronize exactly one *thread* (the one passed during construction time).

```
// Create the promise (the expected result is a id_type)
hpx::distributed::promise<hpx::id_type> p;

// Get the associated future
future<hpx::id_type> f = p.get_future();

// initiate the action supplying the promise as a
// continuation
apply<some_action>(new continuation(p.get_id()), ...);

// Wait for the result to be returned, yielding control
// in the meantime.
hpx::id_type result = f.get();
// ...
```

<sup>812</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/future.hpp>

---

**Note:** The action executed by the promise must return a value of a type convertible to the type as specified by the template parameter *RemoteResult*

---

#### Template Parameters

- **Result** – The template parameter *Result* defines the type this promise is expected to return from *promise::get*.
- **RemoteResult** – The template parameter *RemoteResult* defines the type this promise is expected to receive from the remote action.

namespace **lcos**

```
template<typename Result, typename RemoteResult, typename ComponentTag>
class base_lco_with_value : public hpx::lcos::base_lco, public ComponentTag
    #include <base_lco_with_value.hpp>
template<typename Action, typename Result, bool DirectExecute>
class packaged_action
    #include <packaged_action.hpp>
```

namespace **lcos**

### hpx/async\_distributed/transfer\_continuation\_action.hpp

Defined in header *hpx/async\_distributed/transfer\_continuation\_action.hpp*.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx::async (distributed)

Defined in header *hpx/async.hpp*.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

#### Functions

```
template<typename Action, typename Target, typename ...Ts>
auto async(Action &&action, Target &&target, Ts&&... ts)
```

The distributed implementation of **hpx::async** can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID. The action executes asynchronously.

#### Template Parameters

- **Action** – The type of action instance
- **Target** – The type of target where the action should be executed
- **Ts** – The type of any additional arguments

**Parameters**

- **action** – The action instance to be executed
- **target** – The target where the action should be executed
- **ts** – Additional arguments

**Returns**

`hpx::future` referring to the shared state created by this call to `hpx::async`

**hpx::dataflow (distributed)**

Defined in header `hpx/async.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

```
template<typename Action, typename Target, typename ...Ts>
decltype(auto) dataflow(Action &&action, Target &&target, Ts&&... ts)
```

The distributed implementation of `hpx::dataflow` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID. The action executes asynchronously.

---

**Note:** Its behavior is similar to `hpx::async` with the exception that if one of the arguments is a future, then `hpx::dataflow` will wait for the future to be ready to launch the thread.

---

**Template Parameters**

- **Action** – The type of action instance
- **Target** – The type of target where the action should be executed
- **Ts** – The type of any additional arguments

**Parameters**

- **action** – The action instance to be executed
- **target** – The target where the action should be executed
- **ts** – Additional arguments

**Returns**

`hpx::future` referring to the shared state created by this call to `hpx::dataflow`

## hpx::post (distributed)

Defined in header `hpx/async.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

```
template<typename Action, typename Target, typename ...Ts>  
bool post(Action &&action, Target &&target, Ts&&... ts)
```

The distributed implementation of `hpx::post` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID.

#### Template Parameters

- **Action** – The type of action instance
- **Target** – The type of target where the action should be executed
- **Ts** – The type of any additional arguments

#### Parameters

- **action** – The action instance to be executed
- **target** – The target where the action should be executed
- **ts** – Additional arguments

#### Returns

`true` if the action was successfully posted, `false` otherwise.

## hpx/async\_distributed/promise.hpp

Defined in header `hpx/async_distributed/promise.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
template<>
```

```
class promise<void, hpx::util::unused_type> : public lcos::detail::promise_base<void, hpx::util::unused_type,  
lcos::detail::promise_data<void>>
```

### Public Functions

```
promise() = default
```

constructs a promise object and a shared state.

```
template<typename Allocator>  
inline promise(std::allocator_arg_t, Allocator const &a)
```

constructs a promise object and a shared state. The constructor uses the allocator *to* allocate the memory for the shared state.

**promise**(*promise* &&*other*) noexcept = default

constructs a new promise object and transfers ownership of the shared state of *other* (if any) to the newly-constructed object.

**Post**

*other* has no shared state.

**~promise**() = default

Abandons any shared state.

*promise* &**operator**=(*promise* &&*other*) noexcept = default

Abandons any shared state (30.6.4) and then as if `promise(HPX_MOVE(other)).swap(*this)`.

**Returns**

\*this.

inline void **swap**(*promise* &*other*) noexcept

Exchanges the shared state of \*this and *other*.

**Post**

\*this has the shared state (if any) that *other* had prior to the call to swap. *other* has the shared state (if any) that \*this had prior to the call to swap.

inline void **set\_value**()

atomically stores the value *r* in the shared state and makes that state ready (30.6.4).

**Throws**

**future\_error** – if its shared state already has a stored value. if shared state has no stored value exception is raised. **promise\_already\_satisfied** if its shared state already has a stored value or exception. **no\_state** if \*this has no shared state.

## Private Types

```
using base_type = lcos::detail::promise_base<void, hpx::util::unused_type,
lcos::detail::promise_data<void>>
```

```
template<typename R, typename Allocator>
```

```
struct uses_allocator<hpx::distributed::promise<R>, Allocator> : public true_type
```

```
#include <promise.hpp> Requires: Allocator shall be an allocator (17.6.3.5)
```

```
namespace hpx
```

```
namespace distributed
```

## Functions

```
template<typename Result, typename RemoteResult>
void swap(promise<Result, RemoteResult> &x, promise<Result, RemoteResult> &y) noexcept

template<typename Result, typename RemoteResult>
class promise
    #include <promise.hpp>

template<> unused_type > : public lcos::detail::promise_base< void,
hpx::util::unused_type, lcos::detail::promise_data< void > >
```

## Public Functions

**promise**() = default

constructs a promise object and a shared state.

```
template<typename Allocator>
inline promise(std::allocator_arg_t, Allocator const &a)
```

constructs a promise object and a shared state. The constructor uses the allocator *to* allocate the memory for the shared state.

**promise**(*promise &&other*) noexcept = default

constructs a new promise object and transfers ownership of the shared state of other (if any) to the newly- constructed object.

**Post**

other has no shared state.

**~promise**() = default

Abandons any shared state.

*promise &operator=*(*promise &&other*) noexcept = default

Abandons any shared state (30.6.4) and then as if `promise(HPX_MOVE(other)).swap(*this)`.

**Returns**

\*this.

inline void **swap**(*promise &other*) noexcept

Exchanges the shared state of \*this and other.

**Post**

\*this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that \*this had prior to the call to swap.

inline void **set\_value**()

atomically stores the value r in the shared state and makes that state ready (30.6.4).

**Throws**

**future\_error** – if its shared state already has a stored value. if shared state has no stored value exception is raised. **promise\_already\_satisfied** if its shared state already has a stored value or exception. **no\_state** if \*this has no shared state.

## Private Types

```
using base_type = lcos::detail::promise_base<void, hpx::util::unused_type,  
lcos::detail::promise_data<void>>
```

namespace **std**

```

Allocator > : public true_type  
    #include <promise.hpp> Requires: Allocator shall be an allocator (17.6.3.5)
```

## checkpoint

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/checkpoint/checkpoint.hpp

Defined in header `hpx/checkpoint/checkpoint.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

This header defines the `save_checkpoint` and `restore_checkpoint` functions. These functions are designed to help HPX application developer's checkpoint their applications. `Save_checkpoint` serializes one or more objects and saves them as a byte stream. `Restore_checkpoint` converts the byte stream back into instances of the objects.

namespace **hpx**

namespace **util**

## Functions

```
std::ostream &operator<<(std::ostream &ost, checkpoint const &ckp)  
Operator<< Overload
```

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The `operator>>` overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

### Parameters

- **ost** – Output stream to write to.
- **ckp** – Checkpoint to copy from.

### Returns

`Operator<<` returns the ostream object.

```
std::istream &operator>>(std::istream &ist, checkpoint &ckp)  
Operator>> Overload
```

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

**Parameters**

- **ist** – Input stream to write from.
- **ckp** – Checkpoint to write to.

**Returns**

Operator>> returns the ostream object.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint(T &&t, Ts&&... ts)
    Save_checkpoint
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **U** – This parameter is used to make sure that T is not a launch policy or a checkpoint. This forces the compiler to choose the correct overload.

**Parameters**

- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

Save\_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save\_checkpoint will simply return a checkpoint.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint(checkpoint &&c, T &&t, Ts&&... ts)
    Save_checkpoint - Take a pre-initialized checkpoint
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared\_ptr to the component or by passing a component's client instance to save\_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.

**Parameters**

- **c** – Takes a pre-initialized checkpoint to copy data into.

- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

Save\_checkpoint returns a future to a checkpoint with one exception: if you pass `hpx::launch::sync` as the first argument. In this case save\_checkpoint will simply return a checkpoint.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint(hpx::launch p, T &&t, Ts&&... ts)
Save_checkpoint - Policy overload
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a `shared_ptr` to the component or by passing a component's client instance to save\_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.

**Parameters**

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. `async`, `sync`, etc.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

Save\_checkpoint returns a future to a checkpoint with one exception: if you pass `hpx::launch::sync` as the first argument. In this case save\_checkpoint will simply return a checkpoint.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint(hpx::launch p, checkpoint &&c, T &&t, Ts&&... ts)
Save_checkpoint - Policy overload & pre-initialized checkpoint
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a `shared_ptr` to the component or by passing a component's client instance to save\_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save\_checkpoint will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.
- **ts** – More containers passed to save\_checkpoint to be serialized and placed into a checkpoint object.

**Parameters**

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. `async`, `sync`, etc.
- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.

- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

Save\_checkpoint returns a future to a checkpoint with one exception: if you pass `hpx::launch::sync` as the first argument. In this case `save_checkpoint` will simply return a checkpoint.

```
template<typename T, typename ...Ts>
checkpoint save_checkpoint(hpx::launch::sync_policy sync_p, T &&t, Ts&&... ts)
    Save_checkpoint - Sync_policy overload
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a `shared_ptr` to the component or by passing a component's client instance to `save_checkpoint`. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used `save_checkpoint` will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to `save_checkpoint` to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to `save_checkpoint` to be serialized and placed into a checkpoint object.
- **U** – This parameter is used to make sure that T is not a checkpoint. This forces the compiler to choose the correct overload.

**Parameters**

- **sync\_p** – `hpx::launch::sync_policy`
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

Save\_checkpoint which is passed `hpx::launch::sync_policy` will return a checkpoint which contains the serialized values checkpoint.

```
template<typename T, typename ...Ts>
checkpoint save_checkpoint(hpx::launch::sync_policy sync_p, checkpoint &&c, T &&t, Ts&&... ts)
    Save_checkpoint - Sync_policy overload & pre-init. checkpoint
```

Save\_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a `shared_ptr` to the component or by passing a component's client instance to `save_checkpoint`. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used `save_checkpoint` will simply return a checkpoint object.

**Template Parameters**

- **T** – Containers passed to `save_checkpoint` to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to `save_checkpoint` to be serialized and placed into a checkpoint object.

**Parameters**

- **sync\_p** – `hpx::launch::sync_policy`
- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

Save\_checkpoint which is passed `hpx::launch::sync_policy` will return a checkpoint which contains the serialized values checkpoint.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> prepare_checkpoint(T const &t, Ts const&... ts)
    prepare_checkpoint
```

`prepare_checkpoint` takes the containers which have to be filled from the byte stream by a subsequent `restore_checkpoint` invocation. `prepare_checkpoint` will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

**Template Parameters**

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

`prepare_checkpoint` returns a properly resized checkpoint object that can be used for a subsequent `restore_checkpoint` operation.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> prepare_checkpoint(checkpoint &&c, T const &t, Ts const&... ts)
    prepare_checkpoint
```

`prepare_checkpoint` takes the containers which have to be filled from the byte stream by a subsequent `restore_checkpoint` invocation. `prepare_checkpoint` will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

**Template Parameters**

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

- **c** – Takes a pre-initialized checkpoint to prepare
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

`prepare_checkpoint` returns a properly resized checkpoint object that can be used for a subsequent `restore_checkpoint` operation.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> prepare_checkpoint(hpx::launch p, T const &t, Ts const&... ts)
    prepare_checkpoint
```

`prepare_checkpoint` takes the containers which have to be filled from the byte stream by a subsequent `restore_checkpoint` invocation. `prepare_checkpoint` will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

**Template Parameters**

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

prepare\_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore\_checkpoint operation.

```
template<typename T, typename ...Ts>
hpx::future<checkpoint> prepare_checkpoint(hpx::launch p, checkpoint &&c, T const &t, Ts
                                         const&... ts)
```

prepare\_checkpoint

prepare\_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore\_checkpoint invocation. prepare\_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

**Template Parameters**

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **c** – Takes a pre-initialized checkpoint to prepare
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

prepare\_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore\_checkpoint operation.

```
template<typename T, typename ...Ts>
void restore_checkpoint(checkpoint const &c, T &t, Ts&... ts)
```

Restore\_checkpoint

Restore\_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save\_checkpoint). Restore\_checkpoint can resurrect a stored component in two ways: by passing in an instance of a component's shared\_ptr or by passing in an instance of the component's client.

**Template Parameters**

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

- **c** – The checkpoint to restore.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Returns**

Restore\_checkpoint returns void.

```
class checkpoint
```

```
#include <checkpoint.hpp> Checkpoint Object
```

Checkpoint is the container object which is produced by `save_checkpoint` and is consumed by a `re-store_checkpoint`. A checkpoint may be moved into the `save_checkpoint` object to write the byte stream to the pre-created checkpoint object.

Checkpoints are able to store all containers which are serializable including components.

### hpx/collectives/all\_reduce.hpp

Defined in header `hpx/collectives/all_reduce.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

## Functions

```
template<typename T, typename F>
hpx::future<std::decay_t<T>>> all_reduce(char const *basename, T &&result, F &&op,
                                     num_sites_arg num_sites = num_sites_arg(), this_site_arg
                                     this_site = this_site_arg(), generation_arg generation =
                                     generation_arg(), root_site_arg root_site = root_site_arg())
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

### Parameters

- **basename** – The base name identifying the `all_reduce` operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the `all_reduce` operation performed on the given base name. This is optional and needs to be supplied only if the `all_reduce` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **root\_site** – The site that is responsible for creating the `all_reduce` support object. This value is optional and defaults to '0' (zero).

### Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `all_reduce` operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>>> all_reduce(communicator comm, T &&result, F &&op, this_site_arg
                                     this_site = this_site_arg(), generation_arg generation =
                                     generation_arg())
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_reduce` operation performed on the given base name. This is optional and needs to be supplied only if the `all_reduce` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the `all_reduce` operation performed on the given base name. This is optional and needs to be supplied only if the `all_reduce` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `all_reduce` operation has been completed.

#### Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `all_reduce` operation has been completed.

```
template<typename T, typename F>
decltype(auto) all_reduce(hpx::launch::sync_policy policy, char const *basename, T &&result, F
                        &&op, num_sites_arg num_sites = num_sites_arg(), this_site_arg this_site
                        = this_site_arg(), generation_arg generation = generation_arg(),
                        root_site_arg root_site = root_site_arg())
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the `all_reduce` operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_reduce` operation performed on the given base name. This is optional and needs to be supplied only if the `all_reduce` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site that is responsible for creating the `all_reduce` support object. This value is optional and defaults to '0' (zero).

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T, typename F>
decltype(auto) all_reduce(hpx::launch::sync_policy policy, communicator comm, T &&result, F
                           &&op, this_site_arg this_site = this_site_arg(), generation_arg generation
                           = generation_arg())
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_reduce` operation performed on the given base name. This is optional and needs to be supplied only if the `all_reduce` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the `all_reduce` operation performed on the given base name. This is optional and needs to be supplied only if the `all_reduce` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

### hpx/collectives/reduce\_direct.hpp

Defined in header `hpx/collectives/reduce_direct.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **lcos**

## Functions

```
template<typename Action, typename ReduceOp, typename ArgN, ...  
> hpx::future< decltype(Action(hpx::id_type, ArgN,...  
)> reduce (std::vector< hpx::id_type > const &ids, ReduceOp &&reduce_op,  
ArgN argN,...)
```

Perform a distributed reduction operation.

The function `hpx::lcos::reduce` performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **reduce\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- **argN** – [in] Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.

### Returns

This function returns a future representing the result of the overall reduction operation.

```
template<typename Action, typename ReduceOp, typename ArgN, ...  
> hpx::future< decltype(Action(hpx::id_type, ArgN,...,  
std::size_t))> reduce_with_index (std::vector< hpx::id_type > const &ids,  
ReduceOp &&reduce_op, ArgN argN,...)
```

Perform a distributed reduction operation.

The function `hpx::lcos::reduce_with_index` performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **reduce\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- **argN** – [in] Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.

### Returns

This function returns a future representing the result of the overall reduction operation.

## hpx/collectives/channel\_communicator.hpp

Defined in header `hpx/collectives/channel_communicator.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

### Functions

```
hpx::future<channel_communicator> create_channel_communicator(char const *basename,
                                                                num_sites_arg num_sites =
                                                                num_sites_arg(), this_site_arg
                                                                this_site = this_site_arg())
```

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

---

**Note:** The caller must ensure that the communicator object returned by this function is kept alive (i.e., does not go out of scope) until all participating sites have successfully connected. Destroying the communicator before all sites have reached the creation point may cause the remaining sites to hang indefinitely. Consider using a barrier or similar synchronization mechanism after creating the communicator to ensure all sites are connected before allowing it to be destroyed.

---

#### Parameters

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a future to a new communicator object usable with the collective operation.

```
channel_communicator create_channel_communicator(hpx::launch::sync_policy, char const
                                                    *basename, num_sites_arg num_sites =
                                                    num_sites_arg(), this_site_arg this_site =
                                                    this_site_arg())
```

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

---

**Note:** The caller must ensure that the communicator object returned by this function is kept alive (i.e., does not go out of scope) until all participating sites have successfully connected. Destroying the communicator before all sites have reached the creation point may cause the remaining sites to hang indefinitely. Consider using a barrier or similar synchronization mechanism after creating the communicator to ensure all sites are connected before allowing it to be destroyed.

---

**Parameters**

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a new communicator object usable with the collective operation.

```
template<typename T>
hpx::future<void> set(channel_communicator comm, that_site_arg site, T &&value, tag_arg tag =
    tag_arg())
```

Send a value to the given site

This function sends a value to the given site based on the given communicator.

**Parameters**

- **comm** – The channel communicator object to use for the data transfer
- **site** – The destination site
- **value** – The value to send
- **tag** – The (optional) tag identifying the concrete operation

**Returns**

This function returns a `future<void>` that becomes ready once the data transfer operation has finished.

```
template<typename T>
hpx::future<T> get(channel_communicator comm, that_site_arg site, tag_arg tag = tag_arg())
```

Send a value to the given site

This function receives a value from the given site based on the given communicator.

**Parameters**

- **comm** – The channel communicator object to use for the data transfer
- **site** – The source site

**Returns**

This function returns a `future<T>` that becomes ready once the data transfer operation has finished. The future will hold the received value.

```
class channel_communicator
```

```
    #include <channel_communicator.hpp> A handle identifying the communication channel to use for
    get/set operations
```

## hpx/collectives/gather.hpp

Defined in header `hpx/collectives/gather.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

## Functions

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_here(char const *basename, T &&result,
                                                num_sites_arg num_sites = num_sites_arg(),
                                                this_site_arg this_site = this_site_arg(),
                                                generation_arg generation = generation_arg())
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

### Parameters

- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

### Returns

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_here(communicator comm, T &&result, this_site_arg
                                                this_site = this_site_arg(), generation_arg
                                                generation = generation_arg())
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.

- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

**Returns**

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
hpx::future<void> gather_there(char const *basename, T &&result, this_site_arg this_site =
                                this_site_arg(), generation_arg generation = generation_arg(),
                                root_site_arg root_site = root_site_arg())
```

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

**Parameters**

- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

**Returns**

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
hpx::future<void> gather_there(communicator comm, T &&result, this_site_arg this_site =
                                this_site_arg(), generation_arg generation = generation_arg())
```

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. - **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

**Returns**

This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

```
template<typename T>
decltype(auto) gather_here(hpx::launch::sync_policy, char const *basename, T &&result,
                           num_sites_arg num_sites = num_sites_arg(), this_site_arg this_site =
                           this_site_arg(), generation_arg generation = generation_arg())
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
decltype(auto) gather_here(hpx::launch::sync_policy, communicator comm, T &&result, this_site_arg
                           this_site = this_site_arg(), generation_arg generation = generation_arg())
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. - **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
void gather_there(hpx::launch::sync_policy, char const *basename, T &&result, this_site_arg
                  this_site = this_site_arg(), generation_arg generation = generation_arg(),
                  root_site_arg root_site = root_site_arg())
```

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the gather operation
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
void gather_there(hpx::launch::sync_policy, communicator comm, T &&result, this_site_arg
                  this_site = this_site_arg(), generation_arg generation = generation_arg())
```

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

Gather a given value at the given call site

This function transmits the value given by *result* to a central gather site (where the corresponding *gather\_here* is executed)

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

---

**Note:** The generation values from corresponding *gather\_here* and *gather\_there* have to match.

---

**Parameters**

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central gather point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.

### `hpx/collectives/all_to_all.hpp`

Defined in header `hpx/collectives/all_to_all.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

### Functions

```
template<typename T>
hpx::future<std::vector<T>> all_to_all(char const *basename, std::vector<T> &&local_result,
                                     num_sites_arg num_sites = num_sites_arg(), this_site_arg
                                     this_site = this_site_arg(), generation_arg generation =
                                     generation_arg(), root_site_arg root_site = root_site_arg())
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **basename** – The base name identifying the `all_to_all` operation
- **local\_result** – A vector of values to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_to_all` operation performed on the given base name. This is optional and needs to be supplied only if the `all_to_all` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site that is responsible for creating the `all_to_all` support object. This value is optional and defaults to '0' (zero).

**Returns**

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `all_to_all` operation has been completed.

```
template<typename T>
hpx::future<std::vector<T>> all_to_all(communicator fid, std::vector<T> &&local_result,
                                     this_site_arg this_site = this_site_arg(), generation_arg
                                     generation = generation_arg())
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **fid** – A communicator object returned from *create\_communicator*
- **local\_result** – A vector of values to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_to_all` operation performed on the given base name. This is optional and needs to be supplied only if the `all_to_all` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **fid** – A communicator object returned from *create\_communicator*
- **local\_result** – A vector of values to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the `all_to_all` operation performed on the given base name. This is optional and needs to be supplied only if the `all_to_all` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `all_to_all` operation has been completed.

**Returns**

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `all_to_all` operation has been completed.

```
template<typename T>
std::vector<T> all_to_all(hpx::launch::sync_policy policy, char const *basename, std::vector<T>
                          &&local_result, num_sites_arg num_sites = num_sites_arg(), this_site_arg
                          this_site = this_site_arg(), generation_arg generation = generation_arg(),
                          root_site_arg root_site = root_site_arg())
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the `all_to_all` operation

- **local\_result** – A vector of values to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_to_all` operation performed on the given base name. This is optional and needs to be supplied only if the `all_to_all` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site that is responsible for creating the `all_to_all` support object. This value is optional and defaults to '0' (zero).

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
std::vector<T> all_to_all(hpx::launch::sync_policy policy, communicator fid, std::vector<T>
                        &&local_result, this_site_arg this_site = this_site_arg(), generation_arg
                        generation = generation_arg())
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **fid** – A communicator object returned from `create_communicator`
- **local\_result** – A vector of values to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_to_all` operation performed on the given base name. This is optional and needs to be supplied only if the `all_to_all` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **fid** – A communicator object returned from `create_communicator`
- **local\_result** – A vector of values to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the `all_to_all` operation performed on the given base name. This is optional and needs to be supplied only if the `all_to_all` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

## hpx/collectives/broadcast\_direct.hpp

Defined in header `hpx/collectives/broadcast_direct.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

namespace **lcos**

## Functions

```
template<typename Action, typename ArgN, ...
> hpx::future< std::vector< decltype(Action(hpx::id_type, ArgN,...
))> > broadcast (std::vector< hpx::id_type > const &ids, ArgN argN,...)
```

Perform a distributed broadcast operation.

The function `hpx::lcos::broadcast` performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

---

**Note:** If `decltype(Action(...))` is void, then the result of this function is `future<void>`.

---

### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

### Returns

This function returns a future representing the result of the overall reduction operation.

```
template<typename Action, typename ArgN, ...
> void broadcast_post (std::vector< hpx::id_type > const &ids, ArgN argN,...)
```

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function `hpx::lcos::broadcast_post` performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

**Parameters**

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

```
template<typename Action, typename ArgN, ...  
> hpx::future< std::vector< decltype(Action(hpx::id_type, ArgN,...,  
std::size_t))> > broadcast_with_index (std::vector< hpx::id_type > const &ids,  
ArgN argN,...)
```

Perform a distributed broadcast operation.

The function `hpx::lcos::broadcast_with_index` performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

---

**Note:** If `decltype(Action(...))` is void, then the result of this function is `future<void>`.

---

**Parameters**

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

**Returns**

This function returns a future representing the result of the overall reduction operation.

```
template<typename Action, typename ArgN, ...  
> void broadcast_post_with_index (std::vector< hpx::id_type > const &ids,  
ArgN argN,...)
```

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function `hpx::lcos::broadcast_post_with_index` performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Parameters**

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN** – [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

## hpx/collectives/fold.hpp

Defined in header `hpx/collectives/fold.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **lcos**

### Functions

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...
> hpx::future< decltype(Action(hpx::id_type, ArgN,...
))> fold (std::vector< hpx::id_type > const &ids, FoldOp &&fold_op, Init &&init,
ArgN argN,...)
```

Perform a distributed fold operation.

The function `hpx::lcos::fold` performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

#### Returns

This function returns a future representing the result of the overall folding operation.

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...
> hpx::future< decltype(Action(hpx::id_type, ArgN,...,
std::size_t))> fold_with_index (std::vector< hpx::id_type > const &ids,
FoldOp &&fold_op, Init &&init, ArgN argN,...)
```

Perform a distributed folding operation.

The function `hpx::lcos::fold_with_index` performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

#### Returns

This function returns a future representing the result of the overall folding operation.

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...  
> hpx::future< decltype(Action(hpx::id_type, ArgN,...  
>>> inverse_fold (std::vector< hpx::id_type > const &ids, FoldOp &&fold_op,  
Init &&init, ArgN argN,...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

#### Returns

This function returns a future representing the result of the overall folding operation.

```
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...  
> hpx::future< decltype(Action(hpx::id_type, ArgN,...,  
std::size_t))> inverse_fold_with_index (std::vector< hpx::id_type > const &ids,  
FoldOp &&fold_op, Init &&init, ArgN argN,...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold_with_index` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

---

**Note:** The type of the initial value must be convertible to the result type returned from the invoked action.

---

#### Parameters

- **ids** – [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold\_op** – [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init** – [in] The initial value to be used for the folding operation
- **argN** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

#### Returns

This function returns a future representing the result of the overall folding operation.

### hpx/collectives/argument\_types.hpp

Defined in header `hpx/collectives/argument_types.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

#### Typedefs

using **num\_sites\_arg** = detail::argument\_type<detail::num\_sites\_tag>

The number of participating sites (default: all localities)

using **this\_site\_arg** = detail::argument\_type<detail::this\_site\_tag>

The local end of the communication channel.

using **that\_site\_arg** = detail::argument\_type<detail::that\_site\_tag>

The opposite end of the communication channel.

using **generation\_arg** = detail::argument\_type<detail::generation\_tag>

The generational counter identifying the sequence number of the operation performed on the given base name. It needs to be supplied only if the operation on the given base name has to be performed more than once. It must be a positive number greater than zero. On any given communicator instance, operations that pass an explicit generation may not follow operations that used the default: the internal counter's position is no longer reliably known to the caller. The reverse transition, from explicit numbering back to the default, remains valid.

```
using root_site_arg = detail::argument_type<detail::root_site_tag, 0>
```

The site that is responsible for creating the support object of the operation. It defaults to '0' (zero).

```
using tag_arg = detail::argument_type<detail::tag_tag, 0>
```

The tag identifying the concrete operation.

```
using arity_arg = detail::argument_type<detail::arity_tag, 2>
```

The number of children each of the communication nodes is connected to (default: 2).

```
using flat_fallback_threshold_arg = detail::argument_type<detail::flat_fallback_threshold_tag, 16>
```

The site-count threshold below which a hierarchical\_communicator collapses to a single flat communicator spanning all sites. At small site counts, flat collectives outperform hierarchical composition because tree-walking overhead exceeds the synchronization-depth benefit. Pass 0 to disable the fallback and always build a tree.

## hpx/collectives/all\_gather.hpp

Defined in header `hpx/collectives/all_gather.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

## Functions

```
template<typename T>
```

```
hpx::future<std::vector<std::decay_t<T>>> all_gather(char const *basename, T &&result,  
                                                    num_sites_arg num_sites = num_sites_arg(),  
                                                    this_site_arg this_site = this_site_arg(),  
                                                    generation_arg generation = generation_arg(),  
                                                    root_site_arg root_site = root_site_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

### Parameters

- **basename** – The base name identifying the `all_gather` operation
- **result** – The value to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `all_gather` operation performed on the given base name. This is optional and needs to be supplied only if the `all_gather` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

- **root\_site** – The site that is responsible for creating the all\_gather support object. This value is optional and defaults to '0' (zero).

**Returns**

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_gather operation has been completed.

```
template<typename T>
hpx::future<std::vector<std::decay_t<T>>> all_gather(communicator comm, T &&result,
                                                    this_site_arg this_site = this_site_arg(),
                                                    generation_arg generation =
                                                    generation_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_gather operation has been completed.

**Returns**

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all\_gather operation has been completed.

```
template<typename T>
std::vector<std::decay_t<T>> all_gather(hpx::launch::sync_policy, char const *basename, T
&&result, num_sites_arg num_sites = num_sites_arg(),
this_site_arg this_site = this_site_arg(), generation_arg
generation = generation_arg(), root_site_arg root_site =
root_site_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Parameters**

- **sync\_policy** – The execution policy specifying synchronous execution.

- **basename** – The base name identifying the all\_gather operation
- **result** – The value to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site that is responsible for creating the all\_gather support object. This value is optional and defaults to '0' (zero).

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
std::vector<std::decay_t<T>> all_gather(hpx::launch::sync_policy, communicator comm, T
                                     &&result, this_site_arg this_site = this_site_arg(),
                                     generation_arg generation = generation_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **sync\_policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **sync\_policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the all\_gather operation performed on the given base name. This is optional and needs to be supplied only if the all\_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

## hpx/collectives/scatter.hpp

Defined in header `hpx/collectives/scatter.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

### Functions

```
template<typename T>
hpx::future<T> scatter_from(char const *basename, this_site_arg this_site = this_site_arg(),
                             generation_arg generation = generation_arg(), root_site_arg root_site =
                             root_site_arg())
```

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

#### Parameters

- **basename** – The base name identifying the scatter operation
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

#### Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_from(communicator comm, this_site_arg this_site = this_site_arg(),
                             generation_arg generation = generation_arg())
```

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

**Returns**

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_to(char const *basename, std::vector<T> &&result, num_sites_arg num_sites
                        = num_sites_arg(), this_site_arg this_site = this_site_arg(), generation_arg
                        generation = generation_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

**Parameters**

- **basename** – The base name identifying the scatter operation
- **result** – The value to transmit to the central scatter point from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns**

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
hpx::future<T> scatter_to(communicator comm, std::vector<T> &&result, this_site_arg this_site =
                        this_site_arg(), generation_arg generation = generation_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central scatter point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central scatter point from this call site.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

#### Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

```
template<typename T>
T scatter_from(hpx::launch::sync_policy, char const *basename, this_site_arg this_site =
    this_site_arg(), generation_arg generation = generation_arg(), root_site_arg root_site
    = root_site_arg())
```

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the scatter operation
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

#### Returns

This function returns the scattered value. It executes synchronously and directly returns the result.

```
template<typename T>
T scatter_from(hpx::launch::sync_policy, communicator comm, this_site_arg this_site =
    this_site_arg(), generation_arg generation = generation_arg())
```

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns the scattered value. It executes synchronously and directly returns the result.

#### Returns

This function returns the scattered value. It executes synchronously and directly returns the result.

```
template<typename T>
```

```
T scatter_to(hpx::launch::sync_policy, char const *basename, std::vector<T> &&result,  
            num_sites_arg num_sites = num_sites_arg(), this_site_arg this_site = this_site_arg(),  
            generation_arg generation = generation_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the scatter operation
- **result** – The value to transmit to the central scatter point from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

**Returns**

This function returns the scattered value. It executes synchronously and directly returns the result.

```
template<typename T>
T scatter_to(hpx::launch::sync_policy, communicator comm, std::vector<T> &&result, this_site_arg
            this_site = this_site_arg(), generation_arg generation = generation_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

Scatter (send) a part of the value set at the given call site

This function transmits the value given by *result* to a central scatter site (where the corresponding *scatter\_from* is executed)

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

---

**Note:** The generation values from corresponding *scatter\_to* and *scatter\_from* have to match.

---

**Parameters**

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central scatter point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – The value to transmit to the central scatter point from this call site.
- **generation** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns the scattered value. It executes synchronously and directly returns the result.

**Returns**

This function returns the scattered value. It executes synchronously and directly returns the result.

## hpx::distributed::barrier

Defined in header [hpx/barrier.hpp](#)<sup>813</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

namespace **distributed**

### Functions

explicit **barrier**(std::string const &base\_name)

Creates a barrier, rank is locality id, size is number of localities

A barrier *base\_name* is created. It expects that `hpx::get_num_localities()` participate and the local rank is `hpx::get_locality_id()`.

#### Parameters

**base\_name** – The name of the barrier

**barrier**(std::string const &base\_name, std::size\_t num)

Creates a barrier with a given size, rank is locality id

A barrier *base\_name* is created. It expects that *num* participate and the local rank is `hpx::get_locality_id()`.

#### Parameters

- **base\_name** – The name of the barrier
- **num** – The number of participating threads

**barrier**(std::string const &base\_name, std::size\_t num, std::size\_t rank)

Creates a barrier with a given size and rank

A barrier *base\_name* is created. It expects that *num* participate and the local rank is *rank*.

#### Parameters

- **base\_name** – The name of the barrier
- **num** – The number of participating threads
- **rank** – The rank of the calling site for this invocation

**barrier**(std::string const &base\_name, std::vector<std::size\_t> const &ranks, std::size\_t rank)

Creates a barrier with a vector of ranks

A barrier *base\_name* is created. It expects that `ranks.size()` and the local rank is *rank* (must be contained in *ranks*).

#### Parameters

- **base\_name** – The name of the barrier
- **ranks** – Gives a list of participating ranks (this could be derived from a list of locality ids)

---

<sup>813</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/barrier.hpp>

- **rank** – The rank of the calling site for this invocation

void **wait**() const

Wait until each participant entered the barrier. Must be called by all participants

**Returns**

This function returns once all participants have entered the barrier (have called *wait*).

*hpx::future<void>* **wait**(*hpx::launch::async\_policy*) const

Wait until each participant entered the barrier. Must be called by all participants

**Returns**

a future that becomes ready once all participants have entered the barrier (have called *wait*).

static void **synchronize**()

Perform a global synchronization using the default global barrier. The barrier is created once at startup and can be reused throughout the lifetime of an HPX application.

---

**Note:** This function currently does not support dynamic connection and disconnection of localities.

---

## hpx/collectives/inclusive\_scan.hpp

Defined in header `hpx/collectives/inclusive_scan.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

## Functions

template<typename **T**, typename **F**>

*hpx::future<std::decay\_t<T>>* **inclusive\_scan**(char const \*basename, *T* &&result, *F* &&op,  
                                                           *num\_sites\_arg* num\_sites = *num\_sites\_arg*(),  
                                                           *this\_site\_arg* this\_site = *this\_site\_arg*(),  
                                                           *generation\_arg* generation = *generation\_arg*(),  
                                                           *root\_site\_arg* root\_site = *root\_site\_arg*())

Inclusive `inclusive_scan` a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

**Parameters**

- **basename** – The base name identifying the `inclusive_scan` operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `inclusive_scan` operation performed on the given base name. This is optional and needs to be supplied only if the `inclusive_scan` operation on the given base name has to be performed

more than once. The generation number (if given) must be a positive number greater than zero.

- **root\_site** – The site that is responsible for creating the `inclusive_scan` support object. This value is optional and defaults to '0' (zero).

#### Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `inclusive_scan` operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> inclusive_scan(communicator comm, T &&result, F &&op,
                                           this_site_arg this_site = this_site_arg(),
                                           generation_arg generation = generation_arg())
```

Inclusive `inclusive_scan` a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Inclusive `inclusive_scan` a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

#### Parameters

- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `inclusive_scan` operation performed on the given base name. This is optional and needs to be supplied only if the `inclusive_scan` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the `inclusive_scan` operation performed on the given base name. This is optional and needs to be supplied only if the `inclusive_scan` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `inclusive_scan` operation has been completed.

#### Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `inclusive_scan` operation has been completed.

```
template<typename T, typename F>
decltype(auto) inclusive_scan(hpx::launch::sync_policy, char const *basename, T &&result, F
                               &&op, num_sites_arg num_sites = num_sites_arg(), this_site_arg
                               this_site = this_site_arg(), generation_arg generation =
                               generation_arg(), root_site_arg root_site = root_site_arg())
```

Inclusive inclusive\_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the inclusive\_scan operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the inclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site that is responsible for creating the inclusive\_scan support object. This value is optional and defaults to '0' (zero).

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T, typename F>
decltype(auto) inclusive_scan(hpx::launch::sync_policy, communicator comm, T &&result, F
                               &&op, this_site_arg this_site = this_site_arg(), generation_arg
                               generation = generation_arg())
```

Inclusive inclusive\_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Inclusive inclusive\_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the inclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive\_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the inclusive\_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive\_scan operation on the given base name has to be performed

more than once. The generation number (if given) must be a positive number greater than zero.

- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

## **hpx::distributed::latch**

Defined in header `hpx/latch.hpp`<sup>814</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

namespace **distributed**

class **latch** : public *components::client\_base*<*latch*, *hpx::lcos::server::latch*>

*#include <latch.hpp>* Latch is an implementation of a synchronization primitive that allows multiple threads to wait for a shared event to occur before proceeding. This latch can be invoked in a distributed application.

For a local only latch

**See also:**

`hpx::latch`.

### **Public Functions**

**latch**() = default

explicit **latch**(*std::ptrdiff\_t* count)

Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter\_ == count.

inline **latch**(*hpx::id\_type* const &id)

Extension: Create a client side representation for the existing *server::latch* instance with the given global id *id*.

inline **latch**(*hpx::future*<*hpx::id\_type*> &&f)

Extension: Create a client side representation for the existing *server::latch* instance with the given global id *id*.

---

<sup>814</sup> <http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/include/include/hpx/latch.hpp>

inline **latch**(*hpx::shared\_future*<*hpx::id\_type*> const &id)

Extension: Create a client side representation for the existing *server::latch* instance with the given global id *id*.

inline **latch**(*hpx::shared\_future*<*hpx::id\_type*> &&id)

inline void **count\_down\_and\_wait**()

Decrements counter\_ by 1 . Blocks at the synchronization point until counter\_ reaches 0.

Requires: counter\_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is\_ready calls on this latch that return true.

**Throws**

Nothing. –

inline void **arrive\_and\_wait**()

Decrements counter\_ by update . Blocks at the synchronization point until counter\_ reaches 0.

Requires: counter\_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is\_ready calls on this latch that return true.

**Throws**

Nothing. –

inline void **count\_down**(*std::ptrdiff\_t* n)

Decrements counter\_ by n. Does not block.

Requires: counter\_ >= n and n >= 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is\_ready calls on this latch that return true .

**Throws**

Nothing. –

inline bool **is\_ready**() const noexcept

Returns: counter\_ == 0. Does not block.

**Throws**

Nothing. –

inline bool **try\_wait**() const noexcept

Returns: counter\_ == 0. Does not block.

**Throws**

Nothing. –

inline void **wait**() const

If counter\_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter\_ reaches 0.

**Throws**

Nothing. –

## Private Types

```
typedef components::client_base<latch, hpx::lcos::server::latch> base_type
```

## hpx/collectives/reduce.hpp

Defined in header `hpx/collectives/reduce.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

## Functions

```
template<typename T, typename F>  
hpx::future<std::decay_t<T>> reduce_here(char const *basename, T &&result, F &&op,  
                                         num_sites_arg num_sites = num_sites_arg(), this_site_arg  
                                         this_site = this_site_arg(), generation_arg generation =  
                                         generation_arg())
```

Reduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

### Parameters

- **basename** – The base name identifying the reduce operation
- **result** – A value to reduce on the central reduction point from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

### Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the reduce operation has been completed.

```
template<typename T, typename F>  
hpx::future<decay_t<T>> reduce_here(communicator comm, T &&result, F &&op, this_site_arg  
                                     this_site = this_site_arg(), generation_arg generation =  
                                     generation_arg())
```

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – A value to reduce on the root\_site from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – A value to reduce on the root\_site from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the reduce operation has been completed.

#### Returns

This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the reduce operation has been completed.

```
template<typename T, typename F>
hpx::future<void> reduce_there(char const *basename, T &&result, this_site_arg this_site =
                                this_site_arg(), generation_arg generation = generation_arg(),
                                root_site_arg root_site = root_site_arg())
```

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

#### Parameters

- **basename** – The base name identifying the reduction operation
- **result** – A future referring to the value to transmit to the central reduction point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central reduction point (usually the locality

id). This value is optional and defaults to 0.

#### Returns

This function returns a `future<void>`. It will become ready once the reduction operation has been completed.

```
template<typename T>
hpx::future<void> reduce_there(communicator comm, T &&result, this_site_arg this_site =
                               this_site_arg(), generation_arg generation = generation_arg())
```

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **result** – A value to reduce on the central reduction point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – A value to reduce on the central reduction point from this call site.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the reduce operation has been completed.

#### Returns

This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the reduce operation has been completed.

```
template<typename T, typename F>
decltype(auto) reduce_here(hpx::launch::sync_policy, char const *basename, T &&result, F &&op,
                             num_sites_arg num_sites = num_sites_arg(), this_site_arg this_site =
                             this_site_arg(), generation_arg generation = generation_arg())
```

Reduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the reduce operation
- **result** – A value to reduce on the central reduction point from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

#### Returns

The final reduced value after applying `op` to all contributions.

```
template<typename T, typename F>
decltype(auto) reduce_here(hpx::launch::sync_policy, communicator comm, T &&result, F &&op,
                           this_site_arg this_site = this_site_arg(), generation_arg generation =
                           generation_arg())
```

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – A value to reduce on the root\_site from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – A value to reduce on the root\_site from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied

only if the reduce operation on the given base name has to be performed more than once.  
The generation number (if given) must be a positive number greater than zero.

- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

The final reduced value after applying *op* to all contributions.

**Returns**

The final reduced value after applying *op* to all contributions.

```
template<typename T>
void reduce_there(hpx::launch::sync_policy, char const *basename, T &&result, this_site_arg
                  this_site = this_site_arg(), generation_arg generation = generation_arg(),
                  root_site_arg root_site = root_site_arg())
```

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

**Parameters**

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the reduction operation
- **result** – A future referring to the value to transmit to the central reduction point from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The sequence number of the central reduction point (usually the locality id). This value is optional and defaults to 0.

```
template<typename T>
void reduce_there(hpx::launch::sync_policy, communicator comm, T &&result, this_site_arg
                  this_site = this_site_arg(), generation_arg generation = generation_arg())
```

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

Reduce a given value at the given call site

This function transmits the value given by *result* to a central reduce site (where the corresponding *reduce\_here* is executed)

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

---

**Note:** The generation values from corresponding *reduce\_here* and *reduce\_there* have to match.

---

**Parameters**

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **result** – A value to reduce on the central reduction point from this call site.

- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from `create_communicator`
- **result** – A value to reduce on the central reduction point from this call site.
- **generation** – The generational counter identifying the sequence number of the reduce operation performed on the given base name. This is optional and needs to be supplied only if the reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

### hpx/collectives/create\_communicator.hpp

Defined in header `hpx/collectives/create_communicator.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

### Functions

```
communicator create_communicator(char const *basename, num_sites_arg num_sites =
                                num_sites_arg(), this_site_arg this_site = this_site_arg(),
                                generation_arg generation = generation_arg(), root_site_arg
                                root_site = root_site_arg())
```

Create a new communicator object usable with any collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of the collective operations (such as *all\_gather*, *all\_reduce*, *all\_to\_all*, *broadcast*, etc.).

#### Parameters

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **root\_site** – The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

#### Throws

*hpx::exception* – with *hpx::error::bad\_parameter* if *basename* is null or empty, if the

(resolved) *num\_sites* is zero, if the (resolved) *this\_site* is not smaller than *num\_sites*, or if the (resolved) *root\_site* does not designate a participating site.

#### Returns

This function returns a new communicator object usable with the collective operation.

```
communicator create_local_communicator(char const *basename, num_sites_arg num_sites,  
                                         this_site_arg this_site, generation_arg generation =  
                                         generation_arg(), root_site_arg root_site =  
                                         root_site_arg())
```

Create a new communicator object usable with any local collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of the collective operations (such as *all\_gather*, *all\_reduce*, *all\_to\_all*, *broadcast*, etc.).

#### Parameters

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites
- **this\_site** – The sequence number of this invocation (usually the sequence number of the object participating in the collective operation). This value must be in the range [0, *num\_sites*).
- **generation** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **root\_site** – The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

#### Throws

*hpx::exception* – with *hpx::error::bad\_parameter* if *basename* is null or empty, if *num\_sites* is unspecified or zero, if *this\_site* is unspecified or not smaller than *num\_sites*, or if the (resolved) *root\_site* does not designate a participating site.

#### Returns

This function returns a new communicator object usable for all local collective operations.

```
hierarchical_communicator create_hierarchical_communicator(char const *basename,  
                                                             num_sites_arg num_sites =  
                                                             num_sites_arg(), this_site_arg  
                                                             this_site = this_site_arg(),  
                                                             arity_arg arity = arity_arg(),  
                                                             generation_arg generation =  
                                                             generation_arg(), root_site_arg  
                                                             root_site = root_site_arg(),  
                                                             flat_fallback_threshold_arg  
                                                             threshold =  
                                                             flat_fallback_threshold_arg())
```

Create a new hierarchical communicator object usable with collective operations

This functions creates a new *hierarchical\_communicator* object that can be called in order to pre-allocate a communicator object usable with multiple invocations of a collective operation (such as *all\_gather*, *all\_reduce*, *all\_to\_all*, *broadcast*, etc.).

---

**Note:** The sub-communicators of a *hierarchical\_communicator* share one generation sequence per registered name. Every hierarchical collective advances each sub-communicator it touches by exactly two internal generations per call (a single-pass collective such as *broadcast*, *gather*, *scatter* or *reduce*, and the inter-group exchange of *all\_to\_all*, skip the second generation in one step rather than performing a second round-trip). A single *hierarchical\_communicator* instance may therefore be shared freely

across collective operations, provided every call uses an explicit, strictly consecutive generation number so the shared sequence stays gap-free. Because the two-phase hierarchical collectives (*all\_gather*, *all\_reduce*, *all\_to\_all*, *inclusive\_scan*, *exclusive\_scan* and the hierarchical *barrier*) derive their phase generations from that explicit number, they require it and reject an auto (default) generation. The non-hierarchical (flat) collectives keep supporting the default generation, falling back to the internal per-communicator counter maintained in the *and\_gate*. Once any operation on a communicator has used that default, later operations on the same instance may no longer pass an explicit generation number: the counter's position is no longer reliably known to the caller. The reverse transition, from explicit numbering back to the default, remains valid. All participants of a single operation must use the same generation mode.

---

**Note:** Hierarchical collective overloads that return `hpx::future` may still perform internal waits while walking the communicator tree. They should not be treated as fully non-blocking: validation failures are reported through the returned exceptional future, but internal phase hand-offs can throw or block before that future is delivered.

---

#### Parameters

- **basename** – The base name identifying the collective operation
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **arity** – The arity of the hierarchical tree of communicators to create for the given endpoint. The default arity is 2 and the value must be at least 2.
- **generation** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **root\_site** – The site that is responsible for creating the collective support object. Hierarchical communicators currently support only site 0 as the root, which is also the default.
- **threshold** – The site-count threshold below which the communicator collapses to a single flat communicator spanning all sites (strict comparison: `num_sites < threshold`). The default is 16; pass 0 to disable the fallback and always build a tree.

#### Throws

`hpx::exception` – with `hpx::error::bad_parameter` if *basename* is null or empty, if the (resolved) *num\_sites* is zero, if the (resolved) *this\_site* is not smaller than *num\_sites*, if the (resolved) *root\_site* is not zero, or if *arity* is smaller than 2.

#### Returns

This function returns a new communicator object usable with the collective operation.

struct **communicator**

*#include <create\_communicator.hpp>* A communicator instance represents the list of sites that participate in a particular collective operation.

## Public Functions

void **set\_info**(*num\_sites\_arg* num\_sites, *this\_site\_arg* this\_site) noexcept

Store the number of used sites and the index of the current site for this communicator instance.

### Parameters

- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this site (usually the locality id).

*std::pair<num\_sites\_arg, this\_site\_arg>* **get\_info**() const noexcept

Retrieve the number of used sites and the index of the current site for this communicator instance.

bool **is\_root**() const

Return whether this communicator instance represents the root site of the communication operation.

## hpx/collectives/broadcast.hpp

Defined in header `hpx/collectives/broadcast.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

## Functions

```
template<typename T>
hpx::future<T> broadcast_to(char const *basename, T &&local_result, num_sites_arg num_sites =
    num_sites_arg(), this_site_arg this_site = this_site_arg(),
    generation_arg generation = generation_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

### Parameters

- **basename** – The base name identifying the broadcast operation
- **local\_result** – A value to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

### Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

```
template<typename T>
```

---

```
hpx::future<T> broadcast_to(communicator comm, T &&local_result, this_site_arg this_site =
    this_site_arg(), generation_arg generation = generation_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

#### Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<T> broadcast_to(communicator comm, generation_arg generation, T &&local_result,
    this_site_arg this_site = this_site_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

#### Parameters

- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to transmit to all participating sites from this call site.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<T> broadcast_from(char const *basename, this_site_arg this_site = this_site_arg(),
    generation_arg generation = generation_arg(), root_site_arg
    root_site = root_site_arg())
```

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

#### Parameters

- **basename** – The base name identifying the broadcast operation

- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **root\_site** – The site responsible for broadcasting the value. This is optional and defaults to site 0 (zero).

**Returns**

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

```
template<typename T>
hpx::future<T> broadcast_from(communicator comm, this_site_arg this_site = this_site_arg(),
                             generation_arg generation = generation_arg())
```

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

**Parameters**

- **comm** – A communicator object returned from *create\_communicator*
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create\_communicator*
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

**Returns**

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

```
template<typename T>
```

```
decltype(auto) broadcast_to(hpx::launch::sync_policy policy, char const *basename, T
    &&local_result, num_sites_arg num_sites = num_sites_arg(),
    this_site_arg this_site = this_site_arg(), generation_arg generation =
    generation_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the broadcast operation
- **local\_result** – A value to transmit to all participating sites from this call site.
- **num\_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
decltype(auto) broadcast_to(hpx::launch::sync_policy policy, communicator comm, T
    &&local_result, this_site_arg this_site = this_site_arg(), generation_arg
    generation = generation_arg())
```

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to transmit to all participating sites from this call site.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **policy** – The execution policy specifying synchronous execution.
- **comm** – A communicator object returned from *create\_communicator*
- **local\_result** – A value to transmit to all participating sites from this call site.

- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
T broadcast_from(hpx::launch::sync_policy policy, char const *basename, this_site_arg this_site =
    this_site_arg(), generation_arg generation = generation_arg(), root_site_arg
    root_site = root_site_arg())
```

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

**Parameters**

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the broadcast operation
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site responsible for broadcasting the value. This is optional and defaults to site 0 (zero).

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

```
template<typename T>
T broadcast_from(hpx::launch::sync_policy policy, communicator comm, this_site_arg this_site =
    this_site_arg(), generation_arg generation = generation_arg())
```

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

---

---

**Note:** The generation values from corresponding *broadcast\_to* and *broadcast\_from* have to match.

This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

**Returns**

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

**hpx/collectives/exclusive\_scan.hpp**

Defined in header `hpx/collectives/exclusive_scan.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

Top level HPX namespace.

namespace **collectives**

**Functions**

```
template<typename T, typename F>
hpx::future<std::decay_t<T>>> exclusive_scan(char const *basename, T &&result, F &&op,
                                             num_sites_arg num_sites = num_sites_arg(),
                                             this_site_arg this_site = this_site_arg(),
                                             generation_arg generation = generation_arg(),
                                             root_site_arg root_site = root_site_arg())
```

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

---

**Note:** This no-init overload has MPI\_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

---

**Parameters**

- **basename** – The base name identifying the `exclusive_scan` operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `exclusive_scan` operation performed on the given base name. This is optional and needs to be supplied only if the `exclusive_scan` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site that is responsible for creating the `exclusive_scan` support object. This value is optional and defaults to '0' (zero).

**Returns**

For the participating site *i* this function returns the reduction (calculated according to the function *op*) of the values passed in by the participating sites 0, ..., *i*-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the `exclusive_scan` operation has been completed.

```
template<typename T, typename F>
hpx::future<std::decay_t<T>> exclusive_scan(communicator comm, T &&result, F &&op,
                                           this_site_arg this_site = this_site_arg(),
                                           generation_arg generation = generation_arg())
```

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

---

**Note:** This no-init overload has MPI\_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

**Note:** This no-init overload has MPI\_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

---

**Parameters**

- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `exclusive_scan` operation performed on the given base name. This is optional and needs to be

supplied only if the `exclusive_scan` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

- **comm** – A communicator object returned from `create_communicator`
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the `exclusive_scan` operation performed on the given base name. This is optional and needs to be supplied only if the `exclusive_scan` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

#### Returns

For the participating site *i* this function returns the reduction (calculated according to the function *op*) of the values passed in by the participating sites 0, ..., *i*-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the `exclusive_scan` operation has been completed.

#### Returns

For the participating site *i* this function returns a future the reduction (calculated according to the function *op*) of the values passed in by the participating sites 0, ..., *i*-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the `exclusive_scan` operation has been completed.

```
template<typename T, typename F>
decltype(auto) exclusive_scan(hpx::launch::sync_policy, char const *basename, T &&result, F
                               &&op, num_sites_arg num_sites = num_sites_arg(), this_site_arg
                               this_site = this_site_arg(), generation_arg generation =
                               generation_arg(), root_site_arg root_site = root_site_arg())
```

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

---

**Note:** This no-init overload has MPI\_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

---

#### Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the `exclusive_scan` operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num\_sites** – The number of participating sites (default: all localities).
- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **generation** – The generational counter identifying the sequence number of the `exclusive_scan` operation performed on the given base name. This is optional and needs to be supplied only if the `exclusive_scan` operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root\_site** – The site that is responsible for creating the `exclusive_scan` support object. This value is optional and defaults to '0' (zero).

**Returns**

For the participating site *i* this function returns a future the reduction (calculated according to the function *op*) of the values passed in by the participating sites 0, ..., *i*-1. Participating site 0 returns a value-initialized result. The operation completes before this function returns.

```
template<typename T, typename F>
decltype(auto) exclusive_scan(hpx::launch::sync_policy, communicator comm, T &&result, F
                               &&op, this_site_arg this_site = this_site_arg(), generation_arg
                               generation = generation_arg())
```

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

Exclusive scan a set of values from different call sites

- **this\_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

**Returns**

For the participating site *i* this function returns a future the reduction (calculated according to the function *op*) of the values passed in by the participating sites 0, ..., *i*-1. Participating site 0 returns a value-initialized result. The operation completes before this function returns.

**Returns**

For the participating site *i* this function returns the reduction (calculated according to the function *op*) of the values passed in by the participating sites 0, ..., *i*-1. Participating site 0 returns a value-initialized result. The operation completes before this function returns.

**components**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

**hpx::components::client**

Defined in header `hpx/components.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

```
template<typename Component, typename Data = void>
```

```
class client : public hpx::components::client_base<client<Component, void>, Component, void>
```

*#include <client.hpp>* The client class is a wrapper that manages a distributed component. It extends *client\_base* with specific *Component* and *Data* types.

**Template Parameters**

- **Component** – The type of the component.
- **Data** – The type of the data associated with the client (default is void).

**Public Functions**

```
client() = default
```

```
inline explicit client(hpx::id_type const &id)
```

```
inline explicit client(hpx::id_type &&id)
```

```
inline explicit client(future_type const &f) noexcept
```

```
inline explicit client(future_type &&f) noexcept
```

```
inline client(future<hpx::id_type> &&f) noexcept
```

```
inline client(future<client> &&c)
```

```
client(client const &rhs) noexcept = default
```

```
client(client &&rhs) noexcept = default
```

```
~client() = default
```

```
inline client &operator=(hpx::id_type const &id)
inline client &operator=(hpx::id_type &&id)
inline client &operator=(future_type const &f) noexcept
inline client &operator=(future_type &&f) noexcept
inline client &operator=(future<hpx::id_type> &&f) noexcept
client &operator=(client const &rhs) noexcept = default
client &operator=(client &&rhs) noexcept = default
```

### Private Types

```
using base_type = client_base<client, Component, Data>

using future_type = typename base_type::future_type
```

### **hpx::components::client\_base**

Defined in header `hpx/components.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
template<typename Derived>
struct is_client<Derived, std::void_t<typename Derived::is_client_tag>> : public true_type

namespace hpx
```

```
    namespace components
```

### Functions

```
template<typename Derived, typename Stub, typename Data>
bool operator==(client_base<Derived, Stub, Data> const &lhs, client_base<Derived, Stub, Data>
               const &rhs)

template<typename Derived, typename Stub, typename Data>
bool operator<(client_base<Derived, Stub, Data> const &lhs, client_base<Derived, Stub, Data> const
             &rhs)

template<typename Derived, typename Stub, typename Data>
class client_base : public detail::make_stub::type<Stub>
```

*#include* <*client\_base.hpp*> This class template serves as a base class for client components, providing common functionality such as managing shared state, ID retrieval, and asynchronous operations.

#### Template Parameters

- **Derived** – The derived client component type.
- **Stub** – The stub type used for communication.
- **Data** – The extra data type used for additional information.

## Public Types

using **stub\_argument\_type** = *Stub*

using **server\_component\_type** = typename detail::make\_stub<*Stub*>::server\_component\_type

using **is\_client\_tag** = void

## Public Functions

**client\_base**() = default

inline explicit **client\_base**(id\_type const &id)

inline explicit **client\_base**(id\_type &&id)

## hpx/components/get\_ptr.hpp

Defined in header `hpx/components/get_ptr.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

```
template<typename Component>  
hpx::future<std::shared_ptr<Component>> get_ptr(hpx::id_type const &id)
```

Returns a future referring to the pointer to the underlying memory of a component.

The function `hpx::get_ptr` can be used to extract a future referring to the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise, the function will raise an error.

---

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned `shared_ptr` alive.

---

#### Parameters

**id** – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

#### Template Parameters

**Component** – The type of the server side component.

#### Returns

This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

```
template<typename Derived, typename Stub, typename Data>  
hpx::future<std::shared_ptr<typename components::client_base<Derived, Stub, Data>::server_component_type>> get_ptr(com  
Stu  
Da  
con  
&c
```

Returns a future referring to the pointer to the underlying memory of a component.

The function `hpx::get_ptr` can be used to extract a future referring to the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise, the function will raise an error.

---

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned `shared_ptr` alive.

---

#### Parameters

**c** – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.

#### Returns

This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

```
template<typename Component>
std::shared_ptr<Component> get_ptr(launch::sync_policy p, hpx::id_type const &id, error_code &ec =
                                throws)
```

Returns the pointer to the underlying memory of a component.

The function `hpx::get_ptr_sync` can be used to extract the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise, the function will raise an error.

---

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned `shared_ptr` alive.

---

---

**Note:** As long as *ec* is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of `hpx::exception`.

---

#### Parameters

- **p** – [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- **id** – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

#### Template Parameters

**Component** – The only template parameter has to be the type of the server side component.

#### Returns

This function returns the pointer to the underlying memory for the component instance with the given *id*.

```
template<typename Derived, typename Stub, typename Data>
```

```
std::shared_ptr<typename components::client_base<Derived, Stub, Data>::server_component_type> get_ptr(launch::sync_policy,
com-
po-
nents::client_base
Stub,
Data>
const
&c,
er-
ror_code
&ec
=
throws)
```

Returns the pointer to the underlying memory of a component.

The function `hpx::get_ptr_sync` can be used to extract the pointer to the underlying memory of a given component.

---

**Note:** This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise, the function will raise an error.

---

---

**Note:** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned `shared_ptr` alive.

---

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise, it throws an instance of `hpx::exception`.

---

### Parameters

- **p** – [in] The parameter `p` represents a placeholder type to turn make the call synchronous.
- **c** – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

### Returns

This function returns the pointer to the underlying memory for the component instance with the given `id`.

## hpx/components/basename\_registration.hpp

Defined in header `hpx/components/basename_registration.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

```
template<typename Client>
std::vector<Client> find_all_from_basename(std::string base_name, std::size_t num_ids)
```

Return all registered clients from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return all registered ids from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

---

**Note:** The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

---

**Note:** The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

### Template Parameters

**Client** – The client type to return

### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **num\_ids** – [in] The number of registered ids to expect.
- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **num\_ids** – [in] The number of registered ids to expect.

### Returns

A list of futures representing the ids which were registered using the given base name.

### Returns

A list of futures representing the ids which were registered using the given base name.

```
template<typename Client>
```

```
std::vector<Client> find_all_from_basename(hpx::launch::sync_policy policy, std::string base_name,
                                          std::size_t num_ids)
```

```
template<typename Client>
```

```
std::vector<Client> find_from_basename(std::string base_name, std::vector<std::size_t> const &ids)
```

Return registered clients from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Return registered ids from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

---

**Note:** The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

---

**Note:** The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

### Template Parameters

**Client** – The client type to return

### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **ids** – [in] The sequence numbers of the registered ids.
- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **ids** – [in] The sequence numbers of the registered ids.

### Returns

A list of futures representing the ids which were registered using the given base name and sequence numbers.

### Returns

A list of futures representing the ids which were registered using the given base name and sequence numbers.

```
template<typename Client>
```

```
std::vector<Client> find_from_basename(hpx::launch::sync_policy policy, std::string base_name,
                                          std::vector<std::size_t> const &ids)
```

```
template<typename Client>
```

```
Client find_from_basename(std::string base_name, std::size_t sequence_nr)
```

Return registered id from the given base name and sequence number.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

---

**Note:** The future embedded in the returned client object will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

---

**Note:** The future will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

---

#### Template Parameters

**Client** – The client type to return

#### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in] The sequence number of the registered id.
- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in] The sequence number of the registered id.

#### Returns

A representing the id which was registered using the given base name and sequence numbers.

#### Returns

A representing the id which was registered using the given base name and sequence numbers.

```
template<typename Client>
```

```
Client find_from_basename(hpx::launch::sync_policy policy, std::string base_name, std::size_t
                           sequence_nr)
```

```
template<typename Client, typename Stub, typename Data>
```

```
hpx::future<bool> register_with_basename(std::string base_name, components::client_base<Client, Stub,
                                         Data> &client, std::size_t sequence_nr)
```

Register the id wrapped in the given client using the given base name.

The function registers the object the given client refers to using the provided base name.

---

**Note:** The operation will fail if the given sequence number is not unique.

---

#### Template Parameters

**Client** – The client type to register

#### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **client** – [in] The client which should be registered using the given base name.

- **sequence\_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

**Returns**

A future representing the result of the registration operation itself.

```
template<typename Client>
```

```
Client unregister_with_basename(std::string base_name, std::size_t sequence_nr =  
                                ~static_cast<std::size_t>(0))
```

Unregister the given id using the given base name.

Unregister the given base name.

The function unregisters the given ids using the provided base name.

The function unregisters the given ids using the provided base name.

**Template Parameters**

**Client** – The client type to return

**Parameters**

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register\_with\_basename* before.
- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **sequence\_nr** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register\_with\_basename* before.

**Returns**

A future representing the result of the un-registration operation itself.

**Returns**

A future representing the result of the un-registration operation itself.

**hpx/components/basename\_registration\_fwd.hpp**

Defined in header `hpx/components/basename_registration_fwd.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

## Functions

```
hpx::future<bool> register_with_basename(std::string base_name, hpx::id_type const &id, std::size_t
                                         sequence_nr = ~static_cast<std::size_t>(0))
```

Register the given id using the given base name.

The function registers the given ids using the provided base name.

---

**Note:** The operation will fail if the given sequence number is not unique.

---

### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **id** – [in] The id to register using the given base name.
- **sequence\_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

### Returns

A future representing the result of the registration operation itself.

```
bool register_with_basename(hpx::launch::sync_policy, std::string base_name, hpx::id_type const &id,
                             std::size_t sequence_nr = ~static_cast<std::size_t>(0), error_code &ec =
                             throws)
```

```
hpx::future<bool> register_with_basename(std::string base_name, hpx::future<hpx::id_type> f,
                                         std::size_t sequence_nr = ~static_cast<std::size_t>(0))
```

Register the id wrapped in the given future using the given base name.

The function registers the object the given future refers to using the provided base name.

---

**Note:** The operation will fail if the given sequence number is not unique.

---

### Parameters

- **base\_name** – [in] The base name for which to retrieve the registered ids.
- **f** – [in] The future which should be registered using the given base name.
- **sequence\_nr** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

### Returns

A future representing the result of the registration operation itself.

## components\_base

## hpx/components\_base/get\_lva.hpp

Defined in header `hpx/components_base/get_lva.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

```
template<typename Component, typename Enable = void>
```

```
struct get_lva
```

*#include <get\_lva.hpp>* The `get_lva` template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function `agas::addressing_service::resolve`) to the address of the component implementing the action.

The default implementation uses the template argument *Component* to deduce the type wrapping the component implementing the action. This is used to get the needed address.

### Template Parameters

**Component** – This is the type of the component implementing the action to execute.

## Public Static Functions

```
static inline constexpr Component *call(naming::address_type lva) noexcept
```

## HPX\_REGISTER\_STARTUP\_MODULE

Defined in header `hpx/components.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace components
```

```
        template<bool (*Startup)(startup_function_type&, bool&), bool  
        (*Shutdown)(shutdown_function_type&, bool&)>  
        struct component_startup_shutdown : public component_startup_shutdown_base  
            #include <component_startup_shutdown.hpp> The component_startup_shutdown class provides a  
            minimal implementation of a component's startup/shutdown function provider.
```

## Public Functions

```
inline bool get_startup_function(startup_function_type &startup, bool &pre_startup) override
```

Return any startup function for this component.

### Parameters

- **startup** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.
- **pre\_startup** –

### Returns

Returns *true* if the parameter *startup* has been successfully initialized with the startup function.

```
inline bool get_shutdown_function(shutdown_function_type &shutdown, bool &pre_shutdown)  
                                override
```

Return any startup function for this component.

### Parameters

- **shutdown** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.
- **pre\_shutdown** –

### Returns

Returns *true* if the parameter *shutdown* has been successfully initialized with the shutdown function.

**hpx::components::component, hpx::components::component\_base**

Defined in header `hpx/components.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

template<typename **Component** = void>

class **abstract\_component\_base**

template<typename **Component**, typename **Derived** = void>

class **abstract\_managed\_component\_base**

template<typename **Component**>

class **component**

*#include <components\_base\_fwd.hpp>* The *component* class wraps around a given component type, adding additional type aliases and constructors. It inherits from the specified component type.

template<typename **Component** = void>

class **component\_base**

*#include <components\_base\_fwd.hpp>* *component\_base* serves as a base class for components. It provides common functionality needed by components, such as address and ID retrieval. The template parameter *Component* specifies the derived component type.

template<typename **Component**>

class **fixed\_component**

template<typename **Component**>

class **fixed\_component\_base**

template<typename **Component**, typename **Derived**>

class **managed\_component**

*#include <managed\_component\_base.hpp>* The *managed\_component* template is used as an indirection layer for components allowing to gracefully handle the access to non-existing components.

Additionally, it provides memory management capabilities for the wrapping instances, and it integrates the memory management with the AGAS service. Every instance of a *managed\_component* gets assigned a global id. The provided memory management allocates the *managed\_component* instances from a special heap, ensuring fast allocation and avoids a full network round trip to the AGAS service for each of the allocated instances.

**Template Parameters**

- **Component** – Component type
- **Derived** – Most derived component type

template<typename **Component**, typename **Wrapper**, typename **CtorPolicy**, typename **DtorPolicy**>

class **managed\_component\_base**

## hpx/components\_base/agas\_interface.hpp

Defined in header `hpx/components_base/agas_interface.hpp`.

## HPX\_REGISTER\_COMMANDLINE\_MODULE

Defined in header `hpx/components.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

```

struct component_commandline : public component_commandline_base
    #include <component_commandline.hpp> The component_startup_shutdown provides a minimal im-
    plementation of a component's startup/shutdown function provider.

```

### Public Functions

```

inline hpx::program_options::options_description add_commandline_options() override
    Return any additional command line options valid for this component.

```

---

**Note:** This function will be executed by the runtime system during system startup.

---

### Returns

The module is expected to fill a `options_description` object with any additional command line options this component will handle.

namespace **commandline\_options\_provider**

Defined in header hpx/distribution\_policies/target\_distribution\_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

#### Variables

const *target\_distribution\_policy* **target**

A predefined instance of the *target\_distribution\_policy*. It will represent the local locality and will place all items to create here.

struct **target\_distribution\_policy**

*#include <target\_distribution\_policy.hpp>* This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

#### Public Functions

**target\_distribution\_policy()** = default

Default-construct a new instance of a *target\_distribution\_policy*. This policy will represent one locality (the local locality).

inline *target\_distribution\_policy* **operator()** (id\_type const &id) const

Create a new *target\_distribution\_policy* representing the given locality

##### Parameters

**loc** – [in] The locality the new instance should represent

template<typename **Component**, typename ...**Ts**>

inline *hpx::future*<*hpx::id\_type*> **create**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

---

**Note:** This function is part of the placement policy implemented by this class

---

**Parameters**

**vs** – [in] The arguments which will be forwarded to the constructor of the new object.

**Returns**

A future holding the global address which represents the newly created object

```
template<bool WithCount, typename Component, typename ...Ts>
inline hpx::future<std::vector<bulk_locality_result>> bulk_create(std::size_t count, Ts&&... vs)
                                                    const
```

Create multiple objects on the localities associated by this policy instance

---

**Note:** This function is part of the placement policy implemented by this class

---

**Parameters**

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

**Returns**

A future holding the list of global addresses which represent the newly created objects

```
template<typename Action, typename ...Ts>
inline async_result<Action>::type async(launch policy, Ts&&... vs) const

template<typename Action, typename Callback, typename ...Ts>
inline async_result<Action>::type async_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Continuation, typename ...Ts>
inline bool apply(Continuation &&c, launch policy, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename ...Ts>
inline bool apply(launch policy, Ts&&... vs) const

template<typename Action, typename Continuation, typename Callback, typename ...Ts>
inline bool apply_cb(Continuation &&c, launch policy, Callback &&cb, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Callback, typename ...Ts>
inline bool apply_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

```
inline std::size_t get_num_localities() const
```

Returns the number of associated localities for this distribution policy

---

**Note:** This function is part of the creation policy implemented by this class

---

```
inline hpx::id_type get_next_target() const
```

Returns the locality which is anticipated to be used for the next async operation

```
template<typename Action>
struct async_result
    #include <target_distribution_policy.hpp>
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

## Public Types

```
using type = hpx::future<typename traits::promise_local_result<typename
hpx::traits::extract_action<Action>::remote_result_type>::type>
```

## hpx/distribution\_policies/binpacking\_distribution\_policy.hpp

Defined in header `hpx/distribution_policies/binpacking_distribution_policy.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace components
```

## Variables

```
constexpr char const *const default_binpacking_counter_name =
"/runtime{locality/total}/count/component@"
```

```
const binpacking_distribution_policy binpacked
```

A predefined instance of the binpacking *distribution\_policy*. It will represent the local locality and will place all items to create here.

```
struct binpacking_distribution_policy
```

*#include <binpacking\_distribution\_policy.hpp>* This class specifies the parameters for a binpacking distribution policy to use for creating a given number of items on a given set of localities. The binpacking policy will distribute the new objects in a way such that each of the localities will equalize the number of overall objects of this type based on a given criteria (by default this criteria is the overall number of objects of this type).

## Public Functions

inline **binpacking\_distribution\_policy**()

Default-construct a new instance of a `binpacking_distribution_policy`. This policy will represent one locality (the local locality).

inline *binpacking\_distribution\_policy* **operator**() (*std::vector<id\_type>* const &locs, char const \*perf\_counter\_name = *default\_binpacking\_counter\_name*) const

Create a new *default\_distribution* policy representing the given set of localities.

### Parameters

- **locs** – [in] The list of localities the new instance should represent
- **perf\_counter\_name** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

inline *binpacking\_distribution\_policy* **operator**() (*std::vector<id\_type>* &&locs, char const \*perf\_counter\_name = *default\_binpacking\_counter\_name*) const

Create a new *default\_distribution* policy representing the given set of localities.

### Parameters

- **locs** – [in] The list of localities the new instance should represent
- **perf\_counter\_name** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

inline *binpacking\_distribution\_policy* **operator**() (*id\_type* const &loc, char const \*perf\_counter\_name = *default\_binpacking\_counter\_name*) const

Create a new *default\_distribution* policy representing the given locality

### Parameters

- **loc** – [in] The locality the new instance should represent
- **perf\_counter\_name** – [in] The name of the performance counter that should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

template<typename **Component**, typename ...**Ts**>  
inline *hpx::future<hpx::id\_type>* **create**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

### Parameters

- **vs** – [in] The arguments which will be forwarded to the constructor of the new object.

### Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>  
inline *hpx::future<std::vector<bulk\_locality\_result>>* **bulk\_create**(*std::size\_t* count, *Ts*&&... vs) const

Create multiple objects on the localities associated by this policy instance

### Parameters

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

### Returns

A future holding the list of global addresses which represent the newly created objects

```
inline std::string const &get_counter_name() const
```

Returns the name of the performance counter associated with this policy instance.

```
inline std::size_t get_num_localities() const
```

Returns the number of associated localities for this distribution policy

---

**Note:** This function is part of the creation policy implemented by this class

---

## hpx/distribution\_policies/unwrapping\_result\_policy.hpp

Defined in header `hpx/distribution_policies/unwrapping_result_policy.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

struct **unwrapping\_result\_policy**

*#include <unwrapping\_result\_policy.hpp>* This class is a distribution policy that can be used with actions that return futures. For those actions it is possible to apply certain optimizations if the action is invoked synchronously.

### Public Functions

```
inline explicit unwrapping_result_policy(id_type const &id)
```

```
template<typename Client, typename Stub, typename Data>
```

```
inline explicit unwrapping_result_policy(client_base<Client, Stub, Data> const &client)
```

```
template<typename Action, typename ...Ts>
```

```
inline async_result<Action>::type async(launch policy, Ts&&... vs) const
```

```
template<typename Action, typename ...Ts>
```

```
inline async_result<Action>::type async(launch::sync_policy, Ts&&... vs) const
```

```
template<typename Action, typename Callback, typename ...Ts>
```

```
inline async_result<Action>::type async_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

```
template<typename Action, typename Continuation, typename ...Ts>
```

```
inline bool apply(Continuation &&c, launch policy, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename ...Ts>
```

```
inline bool apply(launch policy, Ts&&... vs) const
```

```
template<typename Action, typename Continuation, typename Callback, typename ...Ts>
```

```
inline bool apply_cb(Continuation &&c, launch policy, Callback &&cb, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Callback, typename ...Ts>
inline bool apply_cb(launch policy, Callback &&cb, Ts&&... vs) const

inline hpx::id_type const &get_next_target() const

template<typename Action>

struct async_result
```

## Public Types

```
using type = typename traits::promise_local_result<typename
hpx::traits::extract_action<Action>::remote_result_type>::type
```

## hpx/distribution\_policies/colocating\_distribution\_policy.hpp

Defined in header `hpx/distribution_policies/colocating_distribution_policy.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
namespace components
```

## Variables

```
const colocating_distribution_policy colocated
```

A predefined instance of the co-locating *distribution\_policy*. It will represent the local locality and will place all items to create here.

```
struct colocating_distribution_policy
```

*#include <colocating\_distribution\_policy.hpp>* This class specifies the parameters for a distribution policy to use for creating a given number of items on the locality where a given object is currently placed.

## Public Functions

constexpr **colocating\_distribution\_policy**() = default

Default-construct a new instance of a `colocating_distribution_policy`. This policy will represent the local locality.

inline *colocating\_distribution\_policy* **operator**()(id\_type const &id) const

Create a new `colocating_distribution_policy` representing the locality where the given object is current located

### Parameters

**id** – [in] The global address of the object with which the new instances should be colocated on

template<typename **Client**, typename **Stub**, typename **Data**>

inline *colocating\_distribution\_policy* **operator**()(*client\_base*<*Client*, *Stub*, *Data*> const &client) const

Create a new `colocating_distribution_policy` representing the locality where the given object is current located

### Parameters

**client** – [in] The client side representation of the object with which the new instances should be colocated on

template<typename **Component**, typename ...**Ts**>

inline *hpx::future*<*hpx::id\_type*> **create**(*Ts*&&... vs) const

Create one object on the locality of the object this distribution policy instance is associated with

---

**Note:** This function is part of the placement policy implemented by this class

---

### Parameters

**vs** – [in] The arguments which will be forwarded to the constructor of the new object.

### Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>

inline *hpx::future*<*std::vector*<*bulk\_locality\_result*>> **bulk\_create**(*std::size\_t* count, *Ts*&&... vs) const

Create multiple objects colocated with the object represented by this policy instance

---

**Note:** This function is part of the placement policy implemented by this class

---

### Parameters

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

### Returns

A future holding the list of global addresses which represent the newly created objects

template<typename **Action**, typename ...**Ts**>

inline *async\_result*<*Action*>::type **async**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Callback**, typename ...**Ts**>

inline *async\_result*<*Action*>::type **async\_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Continuation, typename ...Ts>
inline bool apply(Continuation &&c, launch policy, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename ...Ts>
inline bool apply(launch policy, Ts&&... vs) const

template<typename Action, typename Continuation, typename Callback, typename ...Ts>
inline bool apply_cb(Continuation &&c, launch policy, Callback &&cb, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Callback, typename ...Ts>
inline bool apply_cb(launch policy, Callback &&cb, Ts&&... vs) const

inline hpx::id_type get_next_target() const
    Returns the locality which is anticipated to be used for the next async operation
```

## Public Static Functions

```
static inline std::size_t get_num_localities()
    Returns the number of associated localities for this distribution policy
```

---

**Note:** This function is part of the creation policy implemented by this class

---

```
template<typename Action>

struct async_result
    #include <colocating_distribution_policy.hpp>
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

## Public Types

```
using type = hpx::future<typename traits::promise_local_result<typename
hpx::traits::extract_action<Action>::remote_result_type>::type>
```

## hpx/distribution\_policies/default\_distribution\_policy.hpp

Defined in header `hpx/distribution_policies/default_distribution_policy.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

### Variables

const *default\_distribution\_policy* **default\_layout**

A predefined instance of the default *distribution\_policy*. It will represent the local locality and will place all items to create here.

struct **default\_distribution\_policy**

*#include <default\_distribution\_policy.hpp>* This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

### Public Functions

constexpr **default\_distribution\_policy**() = default

Default-construct a new instance of a *default\_distribution\_policy*. This policy will represent one locality (the local locality).

inline *default\_distribution\_policy* **operator()**(std::vector<id\_type> locs) const

Create a new *default\_distribution* policy representing the given set of localities.

#### Parameters

**locs** – [in] The list of localities the new instance should represent

inline *default\_distribution\_policy* **operator()**(id\_type loc) const

Create a new *default\_distribution* policy representing the given locality

#### Parameters

**loc** – [in] The locality the new instance should represent

template<typename **Component**, typename ...**Ts**>

inline *hpx::future<hpx::id\_type>* **create**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

---

**Note:** This function is part of the placement policy implemented by this class

---

#### Parameters

**vs** – [in] The arguments which will be forwarded to the constructor of the new object.

#### Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>

---

```
inline hpx::future<std::vector<bulk_locality_result>> bulk_create(std::size_t count, Ts&&... vs)
                                                    const
```

Create multiple objects on the localities associated by this policy instance

---

**Note:** This function is part of the placement policy implemented by this class

---

#### Parameters

- **count** – [in] The number of objects to create
- **vs** – [in] The arguments which will be forwarded to the constructors of the new objects.

#### Returns

A future holding the list of global addresses that represent the newly created objects

```
template<typename Action, typename ...Ts>
inline async_result<Action>::type async(launch policy, Ts&&... vs) const

template<typename Action, typename Callback, typename ...Ts>
inline async_result<Action>::type async_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Continuation, typename ...Ts>
inline bool apply(Continuation &&c, launch policy, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename ...Ts>
inline bool apply(threads::thread_priority priority, Ts&&... vs) const

template<typename Action, typename Continuation, typename Callback, typename ...Ts>
inline bool apply_cb(Continuation &&c, launch policy, Callback &&cb, Ts&&... vs) const
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

```
template<typename Action, typename Callback, typename ...Ts>
inline bool apply_cb(launch policy, Callback &&cb, Ts&&... vs) const
```

```
inline std::size_t get_num_localities() const
```

Returns the number of associated localities for this distribution policy

---

**Note:** This function is part of the creation policy implemented by this class

---

```
inline hpx::id_type get_next_target() const
```

Returns the locality which is anticipated to be used for the next async operation

```
template<typename Action>
```

```
struct async_result
```

```
    #include <default_distribution_policy.hpp>
```

---

**Note:** This function is part of the invocation policy implemented by this class

---

## Public Types

```
using type = hpx::future<typename traits::promise_local_result<typename  
hpx::traits::extract_action<Action>::remote_result_type>::type>
```

## executors\_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/executors\_distributed/distribution\_policy\_executor.hpp

Defined in header `hpx/executors_distributed/distribution_policy_executor.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    namespace execution
```

```
        namespace experimental
```

## Functions

```
template<typename DistPolicy>  
distribution_policy_executor(DistPolicy&&) ->  
    distribution_policy_executor<std::decay_t<DistPolicy>>
```

```
template<typename DistPolicy> HPX_DEPRECATED_V (1, 9,  
"hpx::parallel::execution::make_distribution_policy_executor is " "deprecated,  
use " "hpx::parallel::execution::distribution_policy_executor instead") distribution_policy
```

Create a new *distribution\_policy\_executor* from the given *distribution\_policy*.

### Parameters

**policy** – The *distribution\_policy* to create an executor from

```
template<typename DistPolicy>
```

```
class distribution_policy_executor
```

*#include <distribution\_policy\_executor.hpp>* A *distribution\_policy\_executor* creates groups of parallel execution agents that execute in threads implicitly created by the executor and placed on any of the associated localities.

### Template Parameters

**DistPolicy** – The distribution policy type for which an executor should be created. The expression *hpx::traits::is\_distribution\_policy\_v<DistPolicy>* must evaluate to true.

## include

See *Public API* for a list of names and headers that are part of the public *HPX* API.

## hpx/experimental/sandbox.hpp

Defined in header `hpx/experimental/sandbox.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **experimental**

namespace **sandbox**

### Functions

*environment\_info* **detect\_environment**()

Detect and return information about the current environment.

inline void **describe\_environment**(*std::ostream* &os)

Print a formatted environment report.

template<typename **F**>

double **measure**(*F* &&fn, *std::size\_t* iterations = 5)

Measure the mean execution time of a callable.

template<typename **SeqFn**, typename **ParFn**>

*benchmark\_report* **benchmark**(*std::string* label, *SeqFn* &&seq\_fn, *ParFn* &&par\_fn, *std::size\_t* iterations = 5)

Compare sequential and parallel execution of the same work.

struct **benchmark\_report**

*#include <sandbox.hpp>* Holds the results of a comparative benchmark.

### Public Functions

void **print**(*std::ostream* &os) const

Print a formatted benchmark report.

#### Parameters

**os** – Output stream.

### Public Members

`std::string label`

User-provided description.

`std::size_t iterations = 0`

Measurement iterations.

`double seq_mean_ms = 0.0`

Sequential mean time (ms)

`double par_mean_ms = 0.0`

Parallel mean time (ms)

`double speedup = 0.0`

$\text{seq\_time} / \text{par\_time}$

`double efficiency_pct = 0.0`

$(\text{speedup} / \text{workers}) * 100$

`std::size_t num_workers = 0`

HPX workers during measurement.

struct **environment\_info**

*#include <sandbox.hpp>* Describes the hardware and runtime environment.

### Public Functions

void **print**(`std::ostream &os`) const

Print a formatted environment report.

#### Parameters

**os** – Output stream.

### Public Members

`std::size_t cores = 0`

Physical CPU cores.

`std::size_t pus = 0`

Processing units (hardware threads)

`std::size_t numa_nodes = 0`

NUMA domains.

```
std::size_t hpx_workers = 0
```

Active HPX worker threads.

```
bool is_sandbox = false
```

Likely constrained environment.

## init\_runtime

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/hpx\_start.hpp

Defined in header `hpx/hpx_start.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

### hpx/hpx\_init.hpp

Defined in header `hpx/hpx_init.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

### hpx::init\_params

Defined in header `hpx/init.hpp`<sup>815</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

```
namespace hpx
```

```
    struct init_params
```

```
        #include <hpx_init_params.hpp> Parameters used to initialize the HPX runtime through hpx::init and hpx::start.
```

---

<sup>815</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init\\_runtime/include/hpx/init.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init_runtime/include/hpx/init.hpp)

## Public Functions

## **hpx::suspend, hpx::resume**

Defined in header [hpx/init.hpp](#)<sup>816</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

int **suspend**(*error\_code* &ec = *throws*)

Suspend the runtime system.

The function *hpx::suspend* is used to suspend the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be empty. This function only be called when the runtime is running, or already suspended in which case this function will do nothing.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

## Parameters

**ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

---

<sup>816</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init\\_runtime/include/hpx/init.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init_runtime/include/hpx/init.hpp)

**Returns**

This function will always return zero.

```
int resume(error_code &ec = throws)
```

Resume the HPX runtime system.

The function `hpx::resume` is used to resume the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be resumed. This function only be called when the runtime suspended, or already running in which case this function will do nothing.

---

**Note:** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

---

**Parameters**

**ec** – [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Returns**

This function will always return zero.

**hpx::init**

Defined in header `hpx/init.hpp`<sup>817</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

```
namespace hpx_startup
```

**Variables**

```
std::function<int(hpx::program_options::variables_map&)> const &get_main_func()
```

```
namespace hpx
```

**Functions**

```
inline int init(std::function<int(hpx::program_options::variables_map&)> f, int argc, char **argv,  
               init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

---

<sup>817</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init\\_runtime/include/hpx/init.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init_runtime/include/hpx/init.hpp)

---

**Note:** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise, it will be executed as specified by the parameter `mode`.

---

### Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

### Returns

The function returns the value, which has been returned from the user supplied `f`.

```
inline int init(std::function<int(int, char*)> f, int argc, char **argv, init_params const &params =  
    init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

---

**Note:** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise, it will be executed as specified by the parameter `mode`.

---

### Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

### Returns

The function returns the value, which has been returned from the user supplied `f`.

---

```
inline int init(int argc, char **argv, init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. This overload expects a user-defined function named `hpx_main` at global scope, which will be used as the entry point for the HPX application.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

---

**Note:** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise, it will be executed as specified by the parameter `mode`.

---

### Parameters

- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

### Returns

The function returns the value, which has been returned from `hpx_main` (or 0 when executed in worker mode).

```
inline int init(std::nullptr_t f, int argc, char **argv, init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

---

**Note:** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise, it will be executed as specified by the parameter `mode`.

---

### Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.

- **argc** – [in] The number of command line arguments passed in **argv**. This is usually the unchanged value as passed by the operating system (to **main()**).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to **main()**).
- **params** – [in] The parameters to the *hpx::init* function (See documentation of *hpx::init\_params*)

**Returns**

The function returns the value, which has been returned from the user supplied *f*.

```
inline int init(init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings). This overload expects a user-defined function named *hpx\_main* at global scope, which will be used as the entry point for the HPX application.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

---

**Note:** The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in *argc/argv*. If not command line arguments are passed, console mode is assumed.

---

---

**Note:** If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section ‘HPX Command Line Options’.

---

**Parameters**

**params** – [in] The parameters to the *hpx::init* function (See documentation of *hpx::init\_params*)

**Returns**

The function returns the value, which has been returned from *hpx\_main* (or 0 when executed in worker mode).

**hpx::finalize, hpx::disconnect**

Defined in header [hpx/init.hpp](#)<sup>818</sup>.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

<sup>818</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init\\_runtime/include/hpx/init.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init_runtime/include/hpx/init.hpp)

## Functions

int **finalize**(double shutdown\_timeout, double localwait = -1.0, *hpx::error\_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function *hpx::finalize* is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on all localities.

The default value (-1.0) will try to find a globally set timeout value (can be set as the configuration parameter *hpx.shutdown\_timeout*), and if that is not set or -1.0 as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The default value (-1.0) will try to find a globally set wait time value (can be set as the configuration parameter "hpx.finalize\_wait\_time"), and if this is not set or -1.0 as well, it will disable any addition local wait time before proceeding.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Using this function is an alternative to *hpx::disconnect*, these functions do not need to be called both.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

### Parameters

- **shutdown\_timeout** – This parameter allows to specify a timeout (in microseconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **localwait** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

### Returns

This function will always return zero.

inline int **finalize**(*hpx::error\_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function *hpx::finalize* is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on all localities.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

Using this function is an alternative to *hpx::disconnect*, these functions do not need to be called both.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

#### Parameters

**ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

This function will always return zero.

void **terminate**()

Terminate any application non-gracefully.

The function *hpx::terminate* is the non-graceful way to exit any application immediately. It can be called from any locality and will terminate all localities currently used by the application.

---

**Note:** This function will cause HPX to call `std::terminate()` on all localities associated with this application. If the function is called not from an HPX thread it will fail and return an error using the argument *ec*.

---

int **disconnect**(double shutdown\_timeout, double localwait = -1.0, *hpx::error\_code* &ec = *throws*)

Disconnect this locality from the application.

The function *hpx::disconnect* can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on this locality.

The default value ( -1.0 ) will try to find a globally set timeout value (can be set as the configuration parameter "hpx.shutdown\_timeout"), and if that is not set or -1.0 as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The default value (-1.0) will try to find a globally set wait time value (can be set as the configuration parameter *hpx.finalize\_wait\_time*), and if this is not set or -1.0 as well, it will disable any addition local wait time before proceeding.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **shutdown\_timeout** – This parameter allows to specify a timeout (in microseconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **localwait** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function will always return zero.

```
inline int disconnect(hpx::error_code &ec = throws)
```

Disconnect this locality from the application.

The function *hpx::disconnect* can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see *hpx::init*) on this locality.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

---

**Parameters**

- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Returns**

This function will always return zero.

```
int stop(hpx::error_code &ec = throws)
```

Stop the runtime system.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called on every locality. This function should be used only if the runtime system was started using *hpx::start*.

**Returns**

The function returns the value, which has been returned from the user supplied main HPX function (usually *hpx\_main*).

## hpx::start

Defined in header `hpx/init.hpp`<sup>819</sup>.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx\_startup**

namespace **hpx**

### Functions

```
inline bool start(std::function<int(hpx::program_options::variables_map&)> f, int argc, char **argv,  
                  init_params const &params = init_params())
```

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution. This overload will not call `hpx_main`.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

---

**Note:** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise, it will be executed as specified by the parameter `mode`.

---

### Parameters

- **f** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **argc** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **argv** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **params** – [in] The parameters to the `hpx::start` function (See documentation of `hpx::init_params`)

### Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

---

<sup>819</sup> [http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init\\_runtime/include/hpx/init.hpp](http://github.com/TheHPXProject/hpx/blob/unknown/libs/full/init_runtime/include/hpx/init.hpp)

---

```
inline bool start(std::function<int(int, char**)> f, int argc, char **argv, init_params const &params =
    init_params())
```

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution. This overload will not call `hpx_main`.

### Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

```
inline bool start(init_params const &params = init_params())
```

Main non-blocking entry point for launching the HPX runtime system.

This is a simplified main, non-blocking entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings). It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution.

---

**Note:** The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. If not command line arguments are passed, console mode is assumed.

---

---

**Note:** If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

---

#### Parameters

**params** – [in] The parameters to the `hpx::start` function (See documentation of `hpx::init_params`)

#### Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

## naming\_base

See *Public API* for a list of names and headers that are part of the public HPX API.

### hpx/naming\_base/unmanaged.hpp

Defined in header `hpx/naming_base/unmanaged.hpp`.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

## Functions

`hpx::id_type unmanaged(hpx::id_type const &id)`

The helper function `hpx::unmanaged` can be used to generate a global identifier which does not participate in the automatic garbage collection.

---

**Note:** This function allows to apply certain optimizations to the process of memory management in HPX. It however requires the user to take full responsibility for keeping the referenced objects alive long enough.

---

### Parameters

**id** – [in] The id to generated the unmanaged global id from This parameter can be itself a managed or a unmanaged global id.

### Returns

This function returns a new global id referencing the same object as the parameter *id*. The only difference is that the returned global identifier does not participate in the automatic garbage collection.

namespace **naming**

## parcelset

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### hpx/parcelset/message\_handler\_fwd.hpp

## Defines

### HPX\_PARCELPORTR\_BACKGROUND\_MODE\_ENUM\_DEPRECATION\_MSG

namespace **hpx**

namespace **parcelset**

## Typedefs

using **parcel\_write\_handler\_type** = *hpx::function*<void(*std::error\_code* const&, *parcelset::parcel* const&)>

The type of the function that can be registered as a parcel write handler using the function *hpx::set\_parcel\_write\_handler*.

---

**Note:** A parcel write handler is a function which is called by the parcel layer whenever a parcel has been sent by the underlying networking library and if no explicit parcel handler function was specified for the parcel.

---

## Enums

enum class **parcelport\_background\_mode** : *std::uint8\_t*

Type of background work to perform.

*Values:*

enumerator **flush\_buffers**

perform buffer flush operations

enumerator **send**  
perform send operations (includes buffer flush)

enumerator **receive**  
perform receive operations

enumerator **all**  
perform all operations

## Functions

namespace **hpx**

namespace **performance\_counters**

class **registry**

#### Public Functions

**registry()** = default

void **clear()**

Reset registry by deleting all stored counter types.

*counter\_status* **add\_counter\_type**(*counter\_info* const &info, *create\_counter\_func* const  
&create\_counter, *discover\_counters\_func* const  
&discover\_counters, *error\_code* &ec = *throws*)

Add a new performance counter type to the (local) registry.

*counter\_status* **discover\_counter\_types**(*discover\_counter\_func* discover\_counter,  
*discover\_counters\_mode* mode, *error\_code* &ec =  
*throws*) const

Call the supplied function for all registered counter types.

*counter\_status* **discover\_counter\_type**(*std::string* const &fullname, *discover\_counter\_func*  
discover\_counter, *discover\_counters\_mode* mode,  
*error\_code* &ec = *throws*)

Call the supplied function for the given registered counter type.

inline *counter\_status* **discover\_counter\_type**(*counter\_info* const &info, *discover\_counter\_func*  
const &f, *discover\_counters\_mode* mode,  
*error\_code* &ec = *throws*)

*counter\_status* **get\_counter\_create\_function**(*counter\_info* const &info, *create\_counter\_func*  
&create\_counter, *error\_code* &ec = *throws*)  
const

Retrieve the counter creation function which is associated with a given counter type.

*counter\_status* **get\_counter\_discovery\_function**(*counter\_info* const &info,  
*discover\_counters\_func* &func, *error\_code*  
&ec) const

Retrieve the counter discovery function which is associated with a given counter type.

*counter\_status* **remove\_counter\_type**(*counter\_info* const &info, *error\_code* &ec = *throws*)

Remove an existing counter type from the (local) registry.

---

**Note:** This doesn't remove existing counters of this type, it just inhibits defining new counters using this type.

---

*counter\_status* **create\_raw\_counter\_value**(*counter\_info* const &info, *std::int64\_t* \*countervalue, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new performance counter instance of type *raw\_counter* based on given counter value.

*counter\_status* **create\_raw\_counter**(*counter\_info* const &info, *hpx::function<std::int64\_t()>* const &f, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new performance counter instance of type *raw\_counter* based on given function returning the counter value.

*counter\_status* **create\_raw\_counter**(*counter\_info* const &info, *hpx::function<std::int64\_t(bool)>* const &f, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new performance counter instance of type *raw\_counter* based on given function returning the counter value.

*counter\_status* **create\_raw\_counter**(*counter\_info* const &info, *hpx::function<std::vector<std::int64\_t>()>* const &f, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new performance counter instance of type *raw\_counter* based on given function returning the counter value.

*counter\_status* **create\_raw\_counter**(*counter\_info* const &info, *hpx::function<std::vector<std::int64\_t>(bool)>* const &f, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new performance counter instance of type *raw\_counter* based on given function returning the counter value.

*counter\_status* **create\_counter**(*counter\_info* const &info, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new performance counter instance based on given counter info.

*counter\_status* **create\_statistics\_counter**(*counter\_info* const &info, *std::string* const &base\_counter\_name, *std::vector<std::size\_t>* const &parameters, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new statistics performance counter instance based on given base counter name and given base time interval (milliseconds).

*counter\_status* **create\_arithmetics\_counter**(*counter\_info* const &info, *std::vector<std::string>* const &base\_counter\_names, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new arithmetics performance counter instance based on given base counter names.

*counter\_status* **create\_arithmetics\_counter\_extended**(*counter\_info* const &info, *std::vector<std::string>* const &base\_counter\_names, *naming::gid\_type* &id, *error\_code* &ec = *throws*)

Create a new extended arithmetics performance counter instance based on given base counter names.

```
counter_status add_counter(hpx::id_type const &id, counter_info const &info, error_code &ec =
    throws)
```

Add an existing performance counter instance to the registry.

```
counter_status remove_counter(counter_info const &info, hpx::id_type const &id, error_code
    &ec = throws)
```

remove the existing performance counter from the registry

```
counter_status get_counter_type(std::string const &name, counter_info &info, error_code &ec
    = throws)
```

Retrieve counter type information for given counter name.

## Public Static Functions

```
static registry &instance()
```

## Protected Functions

```
counter_type_map_type::iterator locate_counter_type(std::string const &type_name)
```

```
counter_type_map_type::const_iterator locate_counter_type(std::string const &type_name)

## hpx/performance\_counters/manage\_counter\_type.hpp

Defined in header `hpx/performance_counters/manage_counter_type.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **performance\_counters**

## Functions

```
counter_status install_counter_type(std::string const &name, hpx::function<std::int64_t(bool)>  
    const &counter_value, std::string const &helptext = "",  
    std::string const &uom = "", counter_type type =  
    counter_type::raw, error_code &ec = throws)
```

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new generic counter type based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this counter type will cause the provided function to be called and the returned value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `'/objectname{locality#<*>/total}/countername'` where `'<*>'` is a zero based integer identifying the locality the counter is created on.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

## Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format `/objectname/countername`.
- **counter\_value** – [in] The function to call whenever the counter value is requested by a consumer.

- **helptext** – [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom** – [in] The unit of measure for the new performance counter type.
- **type** – [in] Type for the new performance counter type.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an *error\_code* from the enum *counter\_status* (also, see note related to parameter *ec*).

```
counter_status install_counter_type(std::string const &name,
                                   hpx::function<std::vector<std::int64_t>(bool)> const
                                   &counter_value, std::string const &helptext = "", std::string
                                   const &uom = "", error_code &ec = throws)
```

Install a new generic performance counter type returning an array of values in a way, that will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new generic counter type that returns an array of values based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this counter type will cause the provided function to be called and the returned array value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `'/objectname{locality#<*>/total}/countername'` where `'<*>'` is a zero based integer identifying the locality the counter is created on.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

#### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format `/objectname/countername`.
- **counter\_value** – [in] The function to call whenever the counter value (array of values) is requested by a consumer.
- **helptext** – [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom** – [in] The unit of measure for the new performance counter type.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an *error\_code* from the enum *counter\_status* (also, see note related to parameter *ec*).

```
void install_counter_type(std::string const &name, counter_type type, error_code &ec = throws)
```

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new counter type based on the provided

*counter\_type\_info*. The counter type will be automatically unregistered during system shutdown.

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countertype.
- **type** – [in] The type of the counters of this counter\_type.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an error\_code from the enum *counter\_status* (also, see note related to parameter *ec*).

*counter\_status* **install\_counter\_type**(*std::string* const &name, *counter\_type* type, *std::string* const &helptext, *std::string* const &uom = "", *std::uint32\_t* version = *HPX\_PERFORMANCE\_COUNTER\_V1*, *error\_code* &ec = *throws*)

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new counter type based on the provided *counter\_type\_info*. The counter type will be automatically unregistered during system shutdown.

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

#### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countertype.
- **type** – [in] The type of the counters of this counter\_type.
- **helptext** – [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom** – [in] The unit of measure for the new performance counter type.
- **version** – [in] The version of the counter type. This is currently expected to be set to *HPX\_PERFORMANCE\_COUNTER\_V1*.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an error\_code from the enum *counter\_status* (also, see note related to parameter *ec*).

```

counter_status install_counter_type(std::string const &name, counter_type type, std::string const
                                   &helptext, create_counter_func const &create_counter,
                                   discover_counters_func const &discover_counters,
                                   std::uint32_t version =
                                   HPX_PERFORMANCE_COUNTER_V1, std::string const
                                   &uom = "", error_code &ec = throws)

```

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function *install\_counter\_type* will register a new generic counter type based on the provided *counter\_type\_info*. The counter type will be automatically unregistered during system shutdown.

---

**Note:** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

---

---

**Note:** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

---

#### Parameters

- **name** – [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countertype.
- **type** – [in] The type of the counters of this counter\_type.
- **helptext** – [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **version** – [in] The version of the counter type. This is currently expected to be set to HPX\_PERFORMANCE\_COUNTER\_V1.
- **create\_counter** – [in] The function which will be called to create a new instance of this counter type.
- **discover\_counters** – [in] The function will be called to discover counter instances which can be created.
- **uom** – [in] The unit of measure of the counter type (default: “”)
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

#### Returns

If successful, this function returns *valid\_data*, otherwise it will either throw an exception or return an *error\_code* from the enum *counter\_status* (also, see note related to parameter *ec*).

### hpx/performance\_counters/counters.hpp

Defined in header `hpx/performance_counters/counters.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **performance\_counters**

## Typedefs

```
typedef hpx::function<naming::gid_type(counter_info const&, error_code&)> create_counter_func
```

This declares the type of a function, which will be called by HPX whenever a new performance counter instance of a particular type needs to be created.

```
typedef hpx::function<bool(counter_info const&, error_code&)> discover_counter_func
```

This declares a type of a function, which will be passed to a *discover\_counters\_func* in order to be called for each discovered performance counter instance.

```
typedef hpx::function<bool(counter_info const&, discover_counter_func const&,  
discover_counters_mode, error_code&)> discover_counters_func
```

This declares the type of a function, which will be called by HPX whenever it needs to discover all performance counter instances of a particular type.

## Enums

```
enum class counter_type
```

*Values:*

```
enumerator text
```

*text* shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

```
enumerator raw
```

*raw* shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

```
enumerator monotonically_increasing
```

*monotonically\_increasing* shows the cumulatively accumulated observed value. It does not deliver an average.

Formula: None. Shows cumulatively accumulated data as collected. Average: None Type: Instantaneous

```
enumerator average_base
```

*average\_base* is used as the base data (denominator) in the computation of time or count averages for the *counter\_type::average\_count* and *counter\_type::average\_timer* counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in fractional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous

```
enumerator average_count
```

*average\_count* shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula:  $(N1 - N0) / (D1 - D0)$ , where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. Average:  $(Nx - N0) / (Dx - D0)$  Type: Average

enumerator **aggregating**

*aggregating* applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula:  $F(Nx)$

enumerator **average\_timer**

*average\_timer* measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula:  $((N1 - N0) / F) / (D1 - D0)$ , where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval. Average:  $((Nx - N0) / F) / (Dx - D0)$  Type: Average

enumerator **elapsed\_time**

*elapsed\_time* shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula:  $(D0 - N0) / F$ , where the nominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. Average:  $(Dx - N0) / F$  Type: Difference

enumerator **histogram**

*histogram* exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter\_value\_array* instead of a *counter\_value*. Those will also not implement the *get\_counter\_value()* functionality. The results are exposed through a separate *get\_counter\_values\_array()* function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

enumerator **raw\_values**

*raw\_values* exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter\_value\_array* instead of a *counter\_value*. Those will also not implement the *get\_counter\_value()* functionality. The results are exposed through a separate *get\_counter\_values\_array()* function.

enumerator **text**

enumerator **raw**

enumerator **monotonically\_increasing**

enumerator **average\_base**

enumerator **average\_count**

enumerator **aggregating**

enumerator **average\_timer**

enumerator **elapsed\_time**

enumerator **histogram**

enumerator **raw\_values**

*raw\_values* counter exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter\_value\_array* instead of a *counter\_value*. Those will also not implement the *get\_counter\_value()* functionality. The results are exposed through a separate *get\_counter\_values\_array()* function.

enum class **counter\_status**

Status and error codes used by the functions related to performance counters.

*Values:*

enumerator **valid\_data**

No error occurred, data is valid.

enumerator **new\_data**

Data is valid and different from last call.

enumerator **invalid\_data**

Some error occurred, data is not value.

enumerator **already\_defined**

The type or instance already has been defined.

enumerator **counter\_unknown**

The counter instance is unknown.

enumerator **counter\_type\_unknown**

The counter type is unknown.

enumerator **generic\_error**

A unknown error occurred.

enumerator **valid\_data**

enumerator **new\_data**

enumerator **invalid\_data**

enumerator **already\_defined**

enumerator **counter\_unknown**

enumerator **counter\_type\_unknown**

enumerator **generic\_error**

## Functions

struct **counter\_info**

## Public Functions

inline explicit **counter\_info**(*counter\_type* type = *counter\_type::raw*)

inline explicit **counter\_info**(*std::string* const &name)

inline **counter\_info**(*counter\_type* type, *std::string* const &name, *std::string* const &helptext = "",  
*std::uint32\_t* version = *HPX\_PERFORMANCE\_COUNTER\_V1*, *std::string*  
const &uom = "")

## Public Members

*counter\_type* **type\_**

The type of the described counter.

*std::uint32\_t* **version\_**

The version of the described counter using the 0xMMmmSSSS scheme

*counter\_status* **status\_**

The status of the counter object.

*std::string* **fullname\_**

The full name of this counter.

*std::string* **helptext\_**

The full descriptive text for this counter.

*std::string* **unit\_of\_measure\_**

The unit of measure for this counter.

## Private Functions

void **serialize**(*serialization::output\_archive* &ar, unsigned int) const

## Functions

bool **default\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&, *discover\_counters\_mode*, *error\_code*&)

Default discovery function for performance counters; to be registered with the counter types. It will pass the *counter\_info* and the *error\_code* to the supplied function.

bool **locality\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&, *discover\_counters\_mode*, *error\_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

*/<objectname>(locality#<locality\_id>/total)/<instancename>*

bool **locality\_pool\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&, *discover\_counters\_mode*, *error\_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

*/<objectname>(locality#<locality\_id>/pool#<pool\_name>/total)/<instancename>*

bool **locality0\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&, *discover\_counters\_mode*, *error\_code*&)

Default discoverer function for AGAS performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

*/<objectname>{locality#0/total}/<instancename>*

bool **locality\_thread\_counter\_discoverer**(*counter\_info* const&, *discover\_counter\_func* const&, *discover\_counters\_mode*, *error\_code*&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

*/<objectname>(locality#<locality\_id>/worker-thread#<threadnum>)/<instancename>*

```
bool locality_pool_thread_counter_discoverer(counter_info const &info,  
                                              discover_counter_func const &f,  
                                              discover_counters_mode mode, error_code  
                                              &ec)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>{locality#<locality_id>/pool#<poolname>/thread#<threadnum> }/<instancename>
```

```
bool locality_pool_thread_no_total_counter_discoverer(counter_info const &info,  
                                                      discover_counter_func const &f,  
                                                      discover_counters_mode mode,  
                                                      error_code &ec)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>{locality#<locality_id>/pool#<poolname>/thread#<threadnum> }/<instancename>
```

This is essentially the same as above just that locality#/total is not supported.

```
bool locality_numa_counter_discoverer(counter_info const&, discover_counter_func const&,  
                                       discover_counters_mode, error_code&)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/<objectname>(locality#<locality_id>/numa-node#<threadnum>)/<instancename>
```

```
naming::gid_type locality_raw_counter_creator(counter_info const&,  
                                                hpx::function<std::int64_t(bool)> const&,  
                                                error_code&)
```

Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

```
/<objectname>(locality#<locality_id>/total)/<instancename>
```

```
naming::gid_type locality_raw_values_counter_creator(counter_info const&,  
                                                       hpx::function<std::vector<std::int64_t>(bool)>  
                                                       const&, error_code&)
```

```
naming::gid_type agas_raw_counter_creator(counter_info const&, error_code&, char const*const)
```

Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

```
/agas(<objectinstance>/total)/<instancename>
```

```
bool agas_counter_discoverer(counter_info const&, discover_counter_func const&,  
                              discover_counters_mode, error_code&)
```

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

```
/agas(<objectinstance>/total)/<instancename>
```

```
naming::gid_type local_action_invocation_counter_creator(counter_info const&,  
                                                           error_code&)
```

```
bool local_action_invocation_counter_discoverer(counter_info const&,  
                                                discover_counter_func const&,  
                                                discover_counters_mode, error_code&)
```

## hpx/performance\_counters/counters\_fwd.hpp

Defined in header `hpx/performance_counters/counters_fwd.hpp`.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

### Defines

`HPX_COUNTER_TYPE_UNSCOPED_ENUM_DEPRECATION_MSG`

`HPX_COUNTER_STATUS_UNSCOPED_ENUM_DEPRECATION_MSG`

`HPX_DISCOVER_COUNTERS_MODE_UNSCOPED_ENUM_DEPRECATION_MSG`

namespace **hpx**

namespace **performance\_counters**

### Enums

enum class **counter\_type** : `std::uint8_t`

*Values:*

enumerator **text**

*text* shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

enumerator **raw**

*raw* shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

enumerator **monotonically\_increasing**

*monotonically\_increasing* shows the cumulatively accumulated observed value. It does not deliver an average.

Formula: None. Shows cumulatively accumulated data as collected. Average: None Type: Instantaneous

enumerator **average\_base**

*average\_base* is used as the base data (denominator) in the computation of time or count averages for the `counter_type::average_count` and `counter_type::average_timer` counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in fractional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous

**enumerator `average_count`**

*average\_count* shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula:  $(N1 - N0) / (D1 - D0)$ , where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. Average:  $(Nx - N0) / (Dx - D0)$  Type: Average

**enumerator `aggregating`**

*aggregating* applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula:  $F(Nx)$

**enumerator `average_timer`**

*average\_timer* measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula:  $((N1 - N0) / F) / (D1 - D0)$ , where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval. Average:  $((Nx - N0) / F) / (Dx - D0)$  Type: Average

**enumerator `elapsed_time`**

*elapsed\_time* shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula:  $(D0 - N0) / F$ , where the nominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. Average:  $(Dx - N0) / F$  Type: Difference

**enumerator `histogram`**

*histogram* exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter\_value\_array* instead of a *counter\_value*. Those will also not implement the *get\_counter\_value()* functionality. The results are exposed through a separate *get\_counter\_values\_array()* function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

**enumerator `raw_values`**

*raw\_values* exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter\_value\_array* instead of a *counter\_value*. Those will also not implement the *get\_counter\_value()* functionality. The results are exposed through a separate *get\_counter\_values\_array()* function.
