template<typename **`ExPolicy`**, typename **`RandomIt`**, typename **`Sent`**, typename **`Pred`** = *hpx*::*parallel*::detail::less, typename **`Proj`** = *hpx*::*identity*>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *RandomIt*> `hpx::ranges::`**`nth_element`**(*ExPolicy* &&policy, *RandomIt* first, *RandomIt* nth, *Sent* last, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel *nth_element* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *nth_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`RandomIt`** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Sent`** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for RandomIt.
- **`Pred`** – Comparison function object which returns true if the first argument is less than the second.
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`nth`** – Refers to the iterator defining the sort partition point

- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

  ```
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked. This defaults to *hpx::identity*.

Returns

The *partition* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *parallel_task_policy* and returns *RandomIt* otherwise. The *nth_element* algorithm returns an iterator equal to last.

template<typename **Rng**, typename **Pred** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::*identity*>
std::ranges::iterator_t<*Rng*> `hpx::ranges::`**`nth_element`**(*Rng* &&rng, *std*::ranges::iterator_t<*Rng*> nth, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel *nth_element* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked. This defaults to *hpx::identity*.

Returns

The *nth_element* algorithm returns returns *std::ranges::iterator_t<Rng>*. The *nth_element* algorithm returns an iterator equal to last.

template<typename **`ExPolicy`**, typename **`Rng`**, typename **`Pred`** = *hpx*::*parallel*::detail::less, typename **`Proj`** = *hpx*::*identity*>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::ranges::iterator_t<*Rng*>> `hpx::ranges::`**`nth_element`**`(`*ExPolicy* &&policy, *Rng* &&rng, *std*::ranges::iterator_ nth, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel *nth_element* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *nth_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **`Rng`** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **`Pred`** – Comparison function object which returns true if the first argument is less than the second.
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`rng`** – Refers to the sequence of elements the algorithm will be applied to.
- **`nth`** – Refers to the iterator defining the sort partition point
- **`pred`** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

  ```
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.
- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked. This defaults to *hpx::identity*.

Returns

The *partition* algorithm returns a hpx::future<*std::ranges::iterator_t<Rng>*> if the execution policy is of type *parallel_task_policy* and returns *std::ranges::iterator_t<Rng>* otherwise. The *nth_element* algorithm returns an iterator equal to last.

hpx/parallel/util/range.hpp

Defined in header hpx/parallel/util/range.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`parallel`**

namespace **`util`**

Typedefs

template<typename **Iterator**, typename **Sentinel** = *Iterator*>

using **range** = *hpx*::*util*::iterator_range<*Iterator*, *Sentinel*>

Functions

template<typename **Iter**, typename **Sent**>
range<*Iter*, *Sent*> **concat**(*range*<*Iter*, *Sent*> const &it1, *range*<*Iter*, *Sent*> const &it2)

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**>
range<*Iter2*, *Iter2*> **init_move**(*range*<*Iter2*, *Sent2*> const &dest, *range*<*Iter1*, *Sent1*> const &src)

Move objects from the range src to dest.

Parameters

- **dest** – **[in]** : range where move the objects
- **src** – **[in]** : range from where move the objects

Returns

range with the objects moved and the size adjusted

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**>
range<*Iter2*, *Sent2*> **uninit_move**(*range*<*Iter2*, *Sent2*> const &dest, *range*<*Iter1*, *Sent1*> const &src)

Move objects from the range src creating them in dest.

Parameters

- **dest** – **[in]** : range where move and create the objects
- **src** – **[in]** : range from where move the objects

Returns

range with the objects moved and the size adjusted

template<typename **Iter**, typename **Sent**>
void **destroy_range**(*range*<*Iter*, *Sent*> r)

destroy a range of objects

Parameters

r – **[in]** : range to destroy

template<typename **Iter**, typename **Sent**>
range<*Iter*, *Sent*> **init**(*range*<*Iter*, *Sent*> const &r, typename *std*::iterator_traits<*Iter*>::value_type &val)

initialize a range of objects with the object val moving across them

Parameters

- **r** – **[in]** : range of elements not initialized
- **val** – **[in]** : object used for the initialization

Returns

range initialized

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>
bool **is_mergeable**(*range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

: indicate if two ranges have a possible merge

Remark

Parameters

- **`src1`** – **[in]** : first range
- **`src2`** – **[in]** : second range
- **`comp`** – **[in]** : object for to compare elements

Returns

true : they can be merged false : they can't be merged

template<typename **`Iter1`**, typename **`Sent1`**, typename **`Iter2`**, typename **`Sent2`**, typename **`Iter3`**, typename **`Sent3`**, typename **`Compare`**>
range<*Iter3*, *Sent3*> **`full_merge`**(*range*<*Iter3*, *Sent3*> const &dest, *range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

Merge two contiguous ranges src1 and src2 , and put the result in the range dest, returning the range merged.

Parameters

- **`dest`** – **[in]** : range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2
- **`src1`** – **[in]** : first range to merge
- **`src2`** – **[in]** : second range to merge
- **`comp`** – **[in]** : comparison object

Returns

range with the elements merged and the size adjusted

template<typename **`Iter1`**, typename **`Sent1`**, typename **`Iter2`**, typename **`Sent2`**, typename **`Value`**, typename **`Compare`**>
range<*Value**> **`uninit_full_merge`**(*range*<*Value**> const &dest, *range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

Merge two contiguous ranges src1 and src2 , and create and move the result in the uninitialized range dest, returning the range merged.

Parameters

- **`dest`** – **[in]** : range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2. Initially is un-initialize memory
- **`src1`** – **[in]** : first range to merge
- **`src2`** – **[in]** : second range to merge
- **`comp`** – **[in]** : comparison object

Returns

range with the elements merged and the size adjusted

template<typename **`Iter1`**, typename **`Sent1`**, typename **`Iter2`**, typename **`Sent2`**, typename **`Compare`**>
range<*Iter2*, *Sent2*> **`half_merge`**(*range*<*Iter2*, *Sent2*> const &dest, *range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *Compare* comp)

: Merge two buffers. The first buffer is in a separate memory

Parameters

- **`dest`** – **[in]** : range where finish the two buffers merged
- **`src1`** – **[in]** : first range to merge in a separate memory
- **`src2`** – **[in]** : second range to merge, in the final part of the range where deposit the final results
- **`comp`** – **[in]** : object for compare two elements of the type pointed by the Iter1 and Iter2

Returns

: range with the two buffers merged

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Iter3**, typename **Sent3**, typename **Compare**>
bool **in_place_merge_uncontiguous**(*range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter2*, *Sent2*> const &src2, *range*<*Iter3*, *Sent3*> &aux, *Compare* comp)

: merge two non contiguous buffers src1 , src2, using the range aux as auxiliary memory

Remark

Parameters
- **src1** – **[in]** : first range to merge
- **src2** – **[in]** : second range to merge
- **aux** – **[in]** : auxiliary range used in the merge
- **comp** – **[in]** : object for to compare elements

Returns
true : not changes done false : changes in the buffers

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>
range<*Iter1*, *Sent1*> **in_place_merge**(*range*<*Iter1*, *Sent1*> const &src1, *range*<*Iter1*, *Sent1*> const &src2, *range*<*Iter2*, *Sent2*> &buf, *Compare* comp)

: merge two contiguous buffers (src1, src2) using buf as auxiliary memory

Remark

Parameters
- **src1** – **[in]** : first range to merge
- **src2** – **[in]** : second range to merge
- **buf** – **[in]** : auxiliary memory used in the merge
- **comp** – **[in]** : object for to compare elements

Returns
true : not changes done false : changes in the buffers

template<typename **Iter1**, typename **Sent1**, typename **Iter2**, typename **Sent2**, typename **Compare**>
void **merge_flow**(*range*<*Iter1*, *Sent1*> rng1, *range*<*Iter2*, *Sent2*> rbuf, *range*<*Iter1*, *Sent1*> rng2, *Compare* cmp)

hpx::remove_copy

Defined in header hpx/algorithm.hpp[707].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::remove_copy_if*

template<typename **InIter**, typename **OutIter**, typename **T** = typename *std*::iterator_traits<*InIter*>::value_type>
OutIter `hpx::remove_copy`(*InIter* first, *InIter* last, *OutIter* dest, *T* const &value)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: *it == value

The assignments in the parallel *remove_copy* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*, here comparison operator.

Template Parameters

- `InIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `OutIter` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `T` – The type that the result of dereferencing FwdIter1 is compared to.

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `value` – Value to be removed.

Returns

The *remove_copy* algorithm returns an *OutIter*. The *remove_copy* algorithm returns the iterator to the element past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **T** = typename *std*::iterator_traits<InIter>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::remove_copy`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* const &value)

---

[707] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved. Executed according to the policy.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: *it == value

The assignments in the parallel *remove_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*, here comparison operator.

Template Parameters

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- `T` – The type that the result of dereferencing FwdIter1 is compared to.

Parameters

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `value` – Value to be removed.

Returns

The *remove_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *remove_copy* algorithm returns the iterator to the element past the last element copied.

hpx::remove_copy_if

Defined in header hpx/algorithm.hpp[708].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::remove_copy*

template<typename **InIter**, typename **OutIter**, typename **Pred**>
OutIter `hpx::`**`remove_copy_if`**(*InIter* first, *InIter* last, *OutIter* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *pred* returns false. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: INVOKE(pred, *it) != false.

The assignments in the parallel *remove_copy_if* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`Pred`** – The type of the function/function object to use (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_copy_if* algorithm returns an *OutIter* The *remove_copy_if* algorithm returns the iterator to the element past the last element copied.

---

[708] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::`**`remove_copy_if`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *pred* returns false. The order of the elements that are not removed is preserved. Executed according to the policy.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: INVOKE(pred, *it) != false.

The assignments in the parallel *remove_copy_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove_copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_copy_if* requires *Pred* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_copy_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *remove_copy_if* algorithm returns the iterator to the element past the last element copied.

hpx::partial_sort_copy

Defined in header hpx/algorithm.hpp[709].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
RandIter `hpx::partial_sort_copy`(*InIter* first, *InIter* last, *RandIter* d_first, *RandIter* d_last, *Comp* &&comp = *Comp*())

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d_first, d_last). At most d_last - d_first of the elements are placed sorted to the range [d_first, d_first + n) where n is the number of elements to sort (n = min(last - first, d_last - d_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: O(N log(min(D,N))), where N = std::distance(first, last) and D = std::distance(d_first, d_last) comparisons.

Template Parameters

- `InIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `RandIter` – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- `Comp` – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `d_first` – Refers to the beginning of the destination range.
- `d_last` – Refers to the end of the destination range.

---

[709] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`comp`** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.

Returns

The *partial_sort_copy* algorithm returns a *RandomIt*. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. d_first + min(last - first, d_last - d_first)

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`RandIter`**, typename **`Comp`** = *hpx*::*parallel*::detail::less>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *RandIter*> `hpx::`**`partial_sort_copy`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *RandIter* d_first, *RandIter* d_last, *Comp* &&comp = *Comp*())

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d_first, d_last). At most d_last - d_first of the elements are placed sorted to the range [d_first, d_first + n) where n is the number of elements to sort (n = min(last - first, d_last - d_first)). Executed according to the policy.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(N log(min(D,N))), where N = std::distance(first, last) and D = std::distance(d_first, d_last) comparisons.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`RandIter`** – The type of the destination iterators used(deduced) This iterator type must meet the requirements of an random iterator.
- **`Comp`** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **`d_first`** – Refers to the beginning of the destination range.
- **`d_last`** – Refers to the end of the destination range.
- **`comp`** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.

Returns

The *partial_sort_copy* algorithm returns a *hpx::future<RandomIt>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandomIt* otherwise. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. d_first + min(last - first, d_last - d_first)

hpx::experimental::reduction_min

Defined in header hpx/algorithm.hpp[710].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *hpx*::*parallel*::detail::min_of<*T*>> `hpx::experimental::`**`reduction_min`**`(`*T*
&va

The function template *reduction_min* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::min_of{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_min* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::min_of{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

Note

In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **`T`** – The value type to be used by the induction object.
- **`Op`** – The type of the binary function (object) used to perform the reduction operation.

---

[710] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Parameters

`var` – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing. The optional *identity* value is used for the reduction operation and defaults to a copy of *var*.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **`T`**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *hpx*::*parallel*::detail::min_of<*T*>> `hpx::experimental::`**`reduction_min`**`(`*T*

hpx::transform_reduce

Defined in header hpx/algorithm.hpp[711].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`transform_reduce`**`(`*ExPolicy* &&policy,
FwdIter first, *FwdIter* last,
T init, *Reduce* &&red_op,
Convert &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))). Executed according to the policy.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

---

[711] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.

- **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel_task_policy* and returns *T* otherwise. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **`InIter`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
T `hpx::`**`transform_reduce`**`(`*InIter* first, *InIter* last, *T* init, *Reduce* &&red_op, *Convert* &&conv_op`)`

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), . . . , conv_op(*(first + (last - first) - 1))).

The difference between *transform_reduce* and *accumulate* is that the behavior of *transform_reduce* may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, . . . , aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, . . . , bK), GENERALIZED_SUM(op, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).
- **`Reduce`** – The type of the binary function object used for the reduction operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`red_op`** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.

- **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```
R fun(const Type &a);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns a *T*. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **T**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::transform_reduce`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *T* init)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2. Executed according to the policy.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as return) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **`first1`** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **`last1`** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **`init`** – The initial value for the sum.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise.

template<typename **`InIter1`**, typename **`InIter2`**, typename **`T`**>
T `hpx::`**`transform_reduce`**(*InIter1* first1, *InIter1* last1, *InIter2* first2, *T* init)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

> **Note**
>
> Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **`InIter1`** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`InIter2`** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`T`** – The type of the value to be used as return) values (deduced).

Parameters

- **`first1`** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **`last1`** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **`init`** – The initial value for the sum.

Returns

The *transform_reduce* algorithm returns a *T*.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`transform_reduce`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2. Executed according to the policy.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`T`** – The type of the value to be used as return) values (deduced).
- **`Reduce`** – The type of the binary function object used for the multiplication operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **`last1`** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **`init`** – The initial value for the sum.
- **`red_op`** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **`conv_op`** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *red_op*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise.

template<typename **InIter1**, typename **InIter2**, typename **T**, typename **Reduce**, typename **Convert**>
T *hpx*::**transform_reduce**(ExPolicy &&policy, *InIter1* first1, *InIter1* last1, *InIter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

Note

Complexity: O(*last* - *first*) applications each of *reduce* and *transform*.

Template Parameters

- **InIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **InIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the algorithm.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.
- **red_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.
- **conv_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *red_op*.

Returns

The *transform_reduce* algorithm returns a *T*.

template<typename **`ExPolicy`**, typename **`Iter`**, typename **`Sent`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`transform_reduce`**(*ExPolicy* &&policy, *Iter* first, *Sent* last, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

> **Note**
>
> GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

>   - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`Iter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.

- **`Sent`** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).
- **`Reduce`** – The type of the binary function object used for the reduction operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`red_op`** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.

- **`conv_op`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel_task_policy* and returns *T* otherwise. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **`Iter`**, typename **`Sent`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
T *hpx*::**`transform_reduce`**(*Iter* first, *Sent* last, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, . . . , aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, . . . , bK), GENERALIZED_SUM(op, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`Iter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **`Sent`** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).
- **`Reduce`** – The type of the binary function object used for the reduction operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **`first`** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`red_op`** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.

- **`conv_op`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns *T*. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **`ExPolicy`**, typename **`Iter`**, typename **`Sent`**, typename **`Iter2`**, typename **`T`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`transform_reduce`**`(`*ExPolicy* &&policy, *Iter* first, *Sent* last, *Iter2* first2, *T* init`)`

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`Iter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **`Sent`** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **`Iter2`** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.

- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel_task_policy* and returns *T* otherwise. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **`Iter`**, typename **`Sent`**, typename **`Iter2`**, typename **`T`**>
T `hpx::`**`transform_reduce`**`(`*Iter* first, *Sent* last, *Iter2* first2, *T* init`)`

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`Iter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **`Sent`** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **`Iter2`** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.

Returns

The *transform_reduce* algorithm returns *T*. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **`ExPolicy`**, typename **`Iter`**, typename **`Sent`**, typename **`Iter2`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::transform_reduce`(*ExPolicy* &&policy, *Iter* first, *Sent* last, *Iter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`Iter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **`Sent`** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **`Iter2`** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.

- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce** – The type of the binary function object used for the reduction operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.

- **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel_task_policy* and returns *T* otherwise. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **Iter**, typename **Sent**, typename **Iter2**, typename **T**, typename **Reduce**, typename **Convert**>
T *hpx*::**transform_reduce**(*Iter* first, *Sent* last, *Iter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`Iter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **`Sent`** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **`Iter2`** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).
- **`Reduce`** – The type of the binary function object used for the reduction operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **`first`** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`red_op`** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.

- **`conv_op`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns *T*. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **`ExPolicy`**, typename **`Rng`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> **`hpx::transform_reduce`**(*ExPolicy* &&policy, *Rng* &&rng, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`Rng`** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).
- **`Reduce`** – The type of the binary function object used for the reduction operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **red_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.
- **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *parallel_task_policy* and returns *T* otherwise. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **Rng**, typename **T**, typename **Reduce**, typename **Convert**>
T *hpx*::**transform_reduce**(*Rng* &&rng, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), …, conv_op(*(first + (last - first) - 1))).

The difference between *transform_reduce* and *accumulate* is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicates *red_op* and *conv_op*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`Rng`** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).
- **`Reduce`** – The type of the binary function object used for the reduction operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **`rng`** – Refers to the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`red_op`** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of *conv_op*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1*, *Type2*, and *Ret* must be such that an object of a type as returned from *conv_op* can be implicitly converted to any of those types.
- **`conv_op`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *Iter* can be dereferenced and then implicitly converted to Type. The type *R* must be such that an object of this type can be implicitly converted to *T*.

Returns

The *transform_reduce* algorithm returns *T*. The *transform_reduce* algorithm returns the result of the generalized sum over the values returned from *conv_op* when applied to the elements given by the input range [first, last).

template<typename **`ExPolicy`**, typename **`Rng`**, typename **`Iter2`**, typename **`T`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`transform_reduce`**(*ExPolicy* &&policy, *Rng* &&rng, *Iter2* first2, *T* init)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(*last* - *first*) applications of the predicate *op2*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`Rng`** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **`Iter2`** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`T`** – The type of the value to be used as return) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`rng`** – Refers to the sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **`init`** – The initial value for the sum.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise.

template<typename **`Rng`**, typename **`Iter2`**, typename **`T`**>
T `hpx::`**`transform_reduce`**`(`*Rng* &&rng, *Iter2* first2, *T* init)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

Note

Complexity: O(*last* - *first*) applications of the predicate *op2*.

Template Parameters

- **`Rng`** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **`Iter2`** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`T`** – The type of the value to be used as return) values (deduced).

Parameters

- **`rng`** – Refers to the sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **`init`** – The initial value for the sum.

Returns

The *transform_reduce* algorithm returns *T*.

template<typename **ExPolicy**, typename **Rng**, typename **Iter2**, typename **T**, typename **Reduce**, typename **Convert**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::transform_reduce`(*ExPolicy* &&policy, *Rng* &&rng, *Iter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(*last* - *first*) applications of the predicate *op2*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.
- **red_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *op2*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **`conv_op`** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *op1*.

Returns

The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise.

template<typename **`Rng`**, typename **`Iter2`**, typename **`T`**, typename **`Reduce`**, typename **`Convert`**>
T *hpx*::**`transform_reduce`**(*Rng* &&rng, *Iter2* first2, *T* init, *Reduce* &&red_op, *Convert* &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

Note

Complexity: O(*last* - *first*) applications of the predicate *op2*.

Template Parameters

- **`Rng`** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **`Iter2`** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`T`** – The type of the value to be used as return) values (deduced).
- **`Reduce`** – The type of the binary function object used for the multiplication operation.
- **`Convert`** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **`rng`** – Refers to the sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **`init`** – The initial value for the sum.
- **`red_op`** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *op2*. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **`conv_op`** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *op1*.

Returns

The *transform_reduce* algorithm returns *T*.

hpx::is_sorted

Defined in header hpx/algorithm.hpp[712].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_sorted_until*

template<typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>
bool `hpx::`**`is_sorted`**(*FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel *is_sorted* algorithm executes in sequential order in the calling thread.

> **Note**
>
> Complexity: at most (N+S-1) comparisons where *N* = distance(first, last). *S* = number of partitions

Template Parameters

- **`FwdIter`** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of an optional function/function object to use.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **`pred`** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

---

[712] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_sorted* algorithm returns a *bool*. The *is_sorted* algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> **hpx::is_sorted**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Determines if the range [first, last) is sorted. Uses pred to compare elements. Executed according to the policy.

The comparison operations in the parallel *is_sorted* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is_sorted* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: at most (N+S-1) comparisons where *N* = distance(first, last). *S* = number of partitions

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is_sorted* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_sorted* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task_execution_policy* and returns *bool* otherwise. The *is_sorted* algorithm returns a bool if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

hpx::is_sorted_until

Defined in header hpx/algorithm.hpp[713].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_sorted*

template<typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>
FwdIter `hpx::is_sorted_until`(*FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel *is_sorted_until* algorithm execute in sequential order in the calling thread.

Note

Complexity: at most (N+S-1) comparisons where *N* = distance(first, last). *S* = number of partitions

Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use.

Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

---

[713] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Returns

The *is_sorted_until* algorithm returns a *FwdIter*. The *is_sorted_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*>::type **hpx::is_sorted_until**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator. Executed according to the policy.

The comparison operations in the parallel *is_sorted_until* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is_sorted_until* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *is_sorted_until* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

  ```
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_sorted_until* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *is_sorted_until* algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

hpx::count

Defined in header hpx/algorithm.hpp[714].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::count_if*

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>
util::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::difference_type>::type `hpx::count`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &value)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*. Executed according to the policy.

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

Note

Complexity: Performs exactly *last* - *first* comparisons.

Note

The comparisons in the parallel *count* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an forward iterator.

---

[714] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **T** – The type of the value to search for (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

Returns

The *count* algorithm returns a *hpx::future<difference_type>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *std::iterator_traits<FwdIterB>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

template<typename **InIter**, typename **T**>
std::iterator_traits<*InIter*>::difference_type `hpx::`**`count`**`(`*InIter* first, *InIter* last, *T* const &value`)`

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given *value*.

Note

Complexity: Performs exactly *last* - *first* comparisons.

Template Parameters

- **InIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

Returns

The *count* algorithm returns a *difference_type* (where *difference_type* is defined by *std::iterator_traits<InIter>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

hpx::count_if

Defined in header hpx/algorithm.hpp[715].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::count*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
util::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::difference_type>::type hpx::**count_if**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true. Executed according to the policy.

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

> **Note**
>
> The assignments in the parallel *count_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

> **Note**
>
> The assignments in the parallel *count_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

---

[715] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *count_if* algorithm returns *hpx::future<difference_type>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *std::iterator_traits<FwdIter>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

template<typename **`InIter`**, typename **`F`**>
std::iterator_traits<*InIter*>::difference_type `hpx::`**`count_if`**(*InIter* first, *InIter* last, *F* &&f)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate *f* returns true.

> **Note**
>
> Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **`InIter`** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *count_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

The *count_if* algorithm returns *difference_type* (where a difference_type is defined by *std::iterator_traits<InIter>::difference_type*. The *count* algorithm returns the number of elements satisfying the given criteria.

hpx::reduce_by_key

Defined in header hpx/algorithm.hpp[716].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Warning

doxygenfunction: Cannot find function "hpx::reduce_by_key" in doxygen xml output for project "hpx" from directory: ../hpx_autodoc

hpx::is_heap

Defined in header hpx/algorithm.hpp[717].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_heap_until*

template<typename **ExPolicy**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> **hpx::is_heap**(*ExPolicy* &&policy, *RandIter* first, *RandIter* last, *Comp* &&comp = *Comp*())

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator<()). Executed according to the policy.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Linear in the distance between *first* and *last*.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

---

[716] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

[717] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`RandIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Comp`** – The type of the function/function object to use (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`comp`** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

Returns

The *is_heap* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *is_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

template<typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
bool `hpx::`**`is_heap`**(*RandIter* first, *RandIter* last, *Comp* &&comp = *Comp*())

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object *comp* (defaults to using operator<()).

comp has to induce a strict weak ordering on the values.

Note

Complexity: Linear in the distance between *first* and *last*.

Template Parameters

- **`RandIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Comp`** – The type of the function/function object to use (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`comp`** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

Returns

The *is_heap* a *bool*. The *is_heap* algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

hpx::is_heap_until

Defined in header hpx/algorithm.hpp[718].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_heap*

template<typename **ExPolicy**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *RandIter*> **hpx::is_heap_until**(*ExPolicy* &&policy, *RandIter* first, *RandIter* last, *Comp* &&comp = *Comp*())

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()). Executed according to the policy.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*.

The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

---

[718] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Returns

The *is_heap_until* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandIter* otherwise. The *is_heap_until* algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

template<typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
RandIter **hpx::is_heap_until**(*RandIter* first, *RandIter* last, *Comp* &&comp = *Comp*())

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

comp has to induce a strict weak ordering on the values.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*.

Template Parameters

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

Returns

The *is_heap_until* algorithm returns a *RandIter*. The *is_heap_until* algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

hpx::make_heap

Defined in header hpx/algorithm.hpp[719].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **RndIter**, typename **Comp**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **hpx::make_heap**(*ExPolicy* &&policy, *RndIter* first, *RndIter* last, *Comp* &&comp)

Constructs a *max heap* in the range [first, last). Executed according to the policy.

---

[719] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The predicate operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *sequential_execution_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *parallel_execution_policy* or *parallel_task_execution_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`RndIter`** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.
- **`Comp`** – Comparison function object (i.e. an object that satisfies the requirements of Compare) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

  ```
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  While the signature does not need to have const &, the function must not modify the objects passed to it and must be able to accept all values of type (possibly *const*) *Type1* and *Type2* regardless of value category (thus, *Type1* & is not allowed, nor is *Type1* unless for *Type1* a move is equivalent to a copy. The types *Type1* and *Type2* must be such that an object of type *RandomIt* can be dereferenced and then implicitly converted to both of them.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **`comp`** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

  ```
  bool comp(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to Type.

Returns

The *make_heap* algorithm returns a *hpx::future<void>* if the execution policy is of type *task_execution_policy* and returns *void* otherwise.

template<typename **`ExPolicy`**, typename **`RndIter`**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> `hpx::make_heap`(*ExPolicy* &&policy, *RndIter* first, *RndIter* last)

Constructs a *max heap* in the range [first, last). Uses the operator < for comparisons. Executed according to the policy.

The predicate operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *sequential_execution_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *make_heap* algorithm invoked with an execution policy object of type *parallel_execution_policy* or *parallel_task_execution_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`RndIter`** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

Returns

The *make_heap* algorithm returns a *hpx::future<void>* if the execution policy is of type *task_execution_policy* and returns *void* otherwise.

template<typename **`RndIter`**, typename **`Comp`**>
void `hpx::make_heap`(*RndIter* first, *RndIter* last, *Comp* &&comp)

Constructs a *max heap* in the range [first, last).

> **Note**
>
> Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

- **`RndIter`** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.
- **`Comp`** – Comparison function object (i.e. an object that satisfies the requirements of Compare) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

```
bool cmp(const Type1 &a, const Type2 &b);
```

While the signature does not need to have const &, the function must not modify the objects passed to it and must be able to accept all values of type (possibly *const*) *Type1* and *Type2* regardless of value category (thus, *Type1* & is not allowed, nor is *Type1* unless for *Type1* a move is equivalent to a copy. The types *Type1* and *Type2* must be such that an object of type *RandomIt* can be dereferenced and then implicitly converted to both of them.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **`comp`** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

  ```
  bool comp(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *RndIter* can be dereferenced and then implicitly converted to Type.

Returns

The *make_heap* algorithm returns a *void*.

template<typename **`RndIter`**>
void *hpx*::**`make_heap`**(*RndIter* first, *RndIter* last)

Constructs a *max heap* in the range [first, last).

Note

Complexity: at most (3*N) comparisons where *N* = distance(first, last).

Template Parameters

`RndIter` – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

Returns

The *make_heap* algorithm returns a *void*.

hpx::mismatch

Defined in header hpx/algorithm.hpp[720].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> `hpx::mismatch`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op* or *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator*== are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

---

[720] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a hpx::future*<std::pair<FwdIter1,FwdIter2>>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> `hpx::`**`mismatch`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most min(last1 - first1, last2 - first2) applications of *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator*== are made.

> **Note**
>
> The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`**>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> `hpx::mismatch`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most last1 - first1 applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator==* are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>> `hpx::`**`mismatch`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most last1 - first1 applications of *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator==* are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`**>
std::pair<*FwdIter1*, *FwdIter2*> `hpx`::**`mismatch`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op* or *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator==* are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **FwdIter1**, typename **FwdIter2**>
std::pair<*FwdIter1*, *FwdIter2*> `hpx`::**`mismatch`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator==* are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>
std::pair<*FwdIter1*, *FwdIter2*> `hpx::mismatch`(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

Note

Complexity: At most last1 - first1 applications of the predicate *op* or *operator*==. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *op* or *operator*== are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename **`FwdIter1`**, typename **`FwdIter2`**>
std::pair<*FwdIter1*, *FwdIter2*> `hpx::`**`mismatch`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

Note

Complexity: At most last1 - first1 applications of *operator==*. If *FwdIter1* and *FwdIter2* meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of *operator==* are made.

Note

The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *mismatch* algorithm returns a *std::pair<FwdIter1,FwdIter2>*. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

hpx::uninitialized_relocate

Defined in header hpx/algorithm.hpp[721].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_relocate_n*

template<typename **InIter1**, typename **InIter2**, typename **FwdIter**>
FwdIter `hpx::`**`uninitialized_relocate`**(*InIter1* first, *InIter2* last, *FwdIter* dest)

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

Note

Complexity: time: O(n), space: O(1) 1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, last): std::distance(first, last)*sizeof(T) bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, last): std::distance(first, last) memory copies of sizeof(T) bytes each are performed. 3) For “non-trivially relocatable” underlying types (T): std::distance(first, last) move assignments and destructions are performed.

Note

Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

Template Parameters

- **`InIter1`** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **`InIter2`** – The type of the source iterator last (deduced). This iterator type must meet the requirements of an input iterator.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

---

[721] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_relocate* algorithm returns *FwdIter*. The *uninitialized_relocate* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

template<typename **ExPolicy**, typename **InIter1**, typename **InIter2**, typename **FwdIter**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::`**`uninitialized_relocate`**(*ExPolicy* &&policy, *InIter1* first, *InIter2* last, *FwdIter* dest)

Relocates the elements in the range defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: time: O(n), space: O(1) 1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, last): std::distance(first, last)*sizeof(T) bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, last): std::distance(first, last) memory copies of sizeof(T) bytes each are performed. 3) For “non-trivially relocatable” underlying types (T): std::distance(first, last) move assignments and destructions are performed.

> **Note**
>
> Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

> **Note**
>
> Parallel execution requires both *first* and *dest* to be contiguous iterators. If either iterator is non-contiguous, the algorithm cannot determine whether the source and destination ranges overlap, and will silently fall back to sequential execution regardless of the execution policy provided.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **`InIter1`** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **`InIter2`** – The type of the source iterator last (deduced). This iterator type must meet the requirements of an input iterator.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range. The assignments in the parallel *uninitialized_relocate_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

Returns

The *uninitialized_relocate* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_relocate* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

hpx::uninitialized_relocate_n

Defined in header hpx/algorithm.hpp[722].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_relocate*

template<typename **`InIter`**, typename **`Size`**, typename **`FwdIter`**>
FwdIter `hpx::`**`uninitialized_relocate_n`**`(`*InIter* first, *Size* count, *FwdIter* dest)

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate_n* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: time: O(n), space: O(1) 1) For "trivially relocatable" underlying types (T) and a contiguous iterator range [first, first+count): `count*sizeof(T)` bytes are copied. 2) For "trivially relocatable" underlying types (T) and a non-contiguous iterator range [first, first+count): `count` memory copies of sizeof(T) bytes each are performed. 3) For "non-trivially relocatable" underlying types (T): `count` move assignments and destructions are performed.

---

[722] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

> **Note**
>
> Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

Template Parameters

- **`InIter`** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **`Size`** – The type of the argument specifying the number of elements to relocate.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_relocate_n* algorithm returns *FwdIter*. The *uninitialized_relocate_n* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

template<typename **`ExPolicy`**, typename **`InIter`**, typename **`Size`**, typename **`FwdIter`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx`::**`uninitialized_relocate_n`**(*ExPolicy* &&policy, *InIter* first, *Size* count, *FwdIter* dest)

Relocates the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the move-construction of an element, all elements left in the input range, as well as all objects already constructed in the destination range are destroyed. After this algorithm completes, the source range should be freed or reused without destroying the objects.

The assignments in the parallel *uninitialized_relocate_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_relocate_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: time: O(n), space: O(1) 1) For “trivially relocatable” underlying types (T) and a contiguous iterator range [first, first+count): `count*sizeof(T)` bytes are copied. 2) For “trivially relocatable” underlying types (T) and a non-contiguous iterator range [first, first+count): `count` memory copies of sizeof(T) bytes each are performed. 3) For “non-trivially relocatable” underlying types (T): `count` move assignments and destructions are performed.

Note

Declare a type as “trivially relocatable” using the `HPX_DECLARE_TRIVIALLY_RELOCATABLE` macros found in <hpx/type_support/is_trivially_relocatable.hpp>.

Note

Parallel execution requires both *first* and *dest* to be contiguous iterators. If either iterator is non-contiguous, the algorithm cannot determine whether the source and destination ranges overlap, and will silently fall back to sequential execution regardless of the execution policy provided.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`InIter`** – The type of the source iterator first (deduced). This iterator type must meet the requirements of an input iterator.
- **`Size`** – The type of the argument specifying the number of elements to relocate.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_relocate_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_relocate_n* algorithm returns the output iterator to the element in the destination range, one past the last element relocated.

hpx::destroy

Defined in header hpx/algorithm.hpp[723].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::destroy_n*

template<typename **`ExPolicy`**, typename **`FwdIter`**>

---

[723] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

util::detail::algorithm_result_t<*ExPolicy*> `hpx::destroy`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last). Executed according to the policy.

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* operations.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *destroy* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

template<typename **`FwdIter`**>
void `hpx::destroy`(*FwdIter* first, *FwdIter* last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).

> **Note**
>
> Complexity: Performs exactly *last* - *first* operations.

Template Parameters

`FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *destroy* algorithm returns a *void*

hpx::destroy_n

Defined in header hpx/algorithm.hpp[724].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::destroy*

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::destroy_n`(*ExPolicy* &&policy, *FwdIter* first, *Size* count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count). Executed according to the policy.

The operations in the parallel *destroy_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The operations in the parallel *destroy_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* operations, if count > 0, no assignments otherwise.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply this algorithm to.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *destroy_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *destroy_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

---

[724] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

template<typename **FwdIter**, typename **Size**>
FwdIter `hpx::destroy_n`(*FwdIter* first, *Size* count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count).

Note

Complexity: Performs exactly *count* operations, if count > 0, no assignments otherwise.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *destroy_n* algorithm returns a *FwdIter* . The *destroy_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

hpx::set_symmetric_difference

Defined in header hpx/algorithm.hpp[725].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter3*>::type `hpx::set_symmetric_difference`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted ranges [first1, last1) and [first2, last2), but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

---

[725] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly std::abs(m-n) times. If m>n, then the last m-n of those elements are copied from [first1,last1), otherwise the last n-m elements are copied from [first2,last2). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (for *sequenced_task_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **`FwdIter1`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_symmetric_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_symmetric_difference* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter3* otherwise. The *set_symmetric_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>
FwdIter3 `hpx::set_symmetric_difference`(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted ranges [first1, last1) and [first2, last2), but not in both of them are copied to the range beginning at *dest*. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly std::abs(m-n) times. If m>n, then the last m-n of those elements are copied from [first1,last1), otherwise the last n-m elements are copied from [first2,last2). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

> **Note**
>
> Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_symmetric_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_symmetric_difference* algorithm returns a *FwdIter3*. The *set_symmetric_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::experimental::for_each_index

Defined in header hpx/algorithm.hpp[726].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`Mapping`**, typename **`Fun`**>
constexpr void `hpx::experimental::`**`for_each_index`**(*Mapping* const &mapping, *Fun* fun)

Calls *fun* with every multidimensional index in the domain of *mapping* (i.e., its extents), in sequential order.

If *fun* returns a result, the result is ignored.

The layout mapping is a hint; implementations are encouraged to choose an iteration order that performs well for the given mapping.

> **Note**
>
> Complexity: Applies *fun* exactly the product of all extents of *mapping* times.

Template Parameters

- **`Mapping`** – A type meeting the layout mapping requirements. Must expose *index_type*, *extents_type*, `static` *rank()*, and *extents()*.
- **`Fun`** – The type of the function/function object to use (deduced). *Fun* must meet *CopyConstructible* and be invocable with exactly *Mapping::rank()* arguments of type *Mapping::index_type*.

Parameters

---

[726] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **mapping** – The layout mapping whose extents define the iteration domain.
- **fun** – Callable invoked as `fun(i0, i1, ...)` for every multidimensional index in the domain.

template<typename **ExPolicy**, typename **Mapping**, typename **Fun**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> `hpx::experimental::`**`for_each_index`**(*ExPolicy* &&policy, *Mapping* const &mapping, *Fun* fun)

Calls *fun* with every multidimensional index in the domain of *mapping* (i.e., its extents), executed according to *policy*.

If *fun* returns a result, the result is ignored.

Note

Complexity: Applies *fun* exactly the product of all extents of *mapping* times.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced).
- **Mapping** – A type meeting the layout mapping requirements. Must meet *CopyConstructible*.
- **Fun** – The type of the function/function object to use (deduced). Must meet *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for scheduling.
- **mapping** – The layout mapping whose extents define the iteration domain.
- **fun** – Callable invoked as `fun(i0, i1, ...)` for every multidimensional index in the domain.

Returns

hpx::future<void> if the execution policy is *sequenced_task_policy* or *parallel_task_policy*, *void* otherwise.

hpx::is_partitioned

Defined in header hpx/algorithm.hpp[727].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter**, typename **Pred**>
bool `hpx::`**`is_partitioned`**(*FwdIter* first, *FwdIter* last, *Pred* &&pred)

Determines if the range [first, last) is partitioned.

---

[727] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: at most (N) predicate evaluations where *N* = distance(first, last).

Template Parameters

- **`FwdIter`** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **`pred`** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_partitioned* algorithm returns *bool*. The *is_partitioned* algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise is_partitioned returns false. If the range [first, last) contains less than two elements, the function is always true.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::`**`is_partitioned`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred)

Determines if the range [first, last) is partitioned. Executed according to the policy.

The predicate operations in the parallel *is_partitioned* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The comparison operations in the parallel *is_partitioned* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: at most (N) predicate evaluations where *N* = distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). *Pred* must be *CopyConstructible* when using a parallel policy.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **`pred`** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *is_partitioned* algorithm returns a *hpx::future<bool>* if the execution policy is of type *task_execution_policy* and returns *bool* otherwise. The *is_partitioned* algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise is_partitioned returns false. If the range [first, last) contains less than two elements, the function is always true.

hpx::transform

Defined in header hpx/algorithm.hpp[728].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`F`**>
FwdIter2 `hpx::`**`transform`**`(`*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *F* &&f`)`

Applies the given function *f* to the range [first, last) and stores the result in another range, beginning at dest.

Note

Complexity: Exactly *last* - *first* applications of *f*

Template Parameters

- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

---

[728] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *Ret* must be such that an object of type *FwdIter2* can be dereferenced and assigned a value of type *Ret*.

Returns

The *transform* algorithm returns a *FwdIter2*. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`F`**>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::`**`transform`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *F* &&f)

Applies the given function *f* to the range [first, last) and stores the result in another range, beginning at dest. Executed according to the policy.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly *last* - *first* applications of *f*

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type &a);
  ```

  The signature does not need to have const&. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*. The type *Ret* must be such that an object of type *FwdIter2* can be dereferenced and assigned a value of type *Ret*.

Returns

The *transform* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel_task_policy* and returns *FwdIter2* otherwise. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`FwdIter3`**, typename **`F`**>
FwdIter3 `hpx::`**`transform`**`(`*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter3* dest, *F* &&f`)`

Applies the given function *f* to pairs of elements from two ranges: one defined by [first1, last1) and the other beginning at first2, and stores the result in another range, beginning at dest.

Note

Complexity: Exactly *last* - *first* applications of *f*

Template Parameters

- **`FwdIter1`** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first1`** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.

- **`last1`** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&. The types *Type1* and *Type2* must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively. The type *Ret* must be such that an object of type *FwdIter3* can be dereferenced and assigned a value of type *Ret*.

Returns

The *transform* algorithm returns a *FwdIter3*. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`FwdIter3`**, typename **`F`**>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter3*> `hpx::`**`transform`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter3* dest, *F* &&f)

Applies the given function *f* to pairs of elements from two ranges: one defined by [first1, last1) and the other beginning at first2, and stores the result in another range, beginning at dest. Executed according to the policy.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The invocations of *f* in the parallel *transform* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Exactly *last* - *first* applications of *f*

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **`FwdIter1`** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&. The types *Type1* and *Type2* must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively. The type *Ret* must be such that an object of type *FwdIter3* can be dereferenced and assigned a value of type *Ret*.

Returns

The *transform* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *parallel_task_policy* and returns *FwdIter3* otherwise. The *transform* algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

hpx::all_of

Defined in header hpx/algorithm.hpp[729].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::any_of*
- *hpx::none_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
util::detail::algorithm_result_t<*ExPolicy*, bool> **hpx::all_of**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Checks if unary predicate *f* returns true for all elements in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

---

[729] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most *last* - *first* applications of the predicate *f*

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *all_of* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *all_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *all_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

template<typename **`ExPolicy`**, typename **`InIter`**, typename **`F`**>
bool *hpx*::**`all_of`**(*InIter* first, *InIter* last, *F* &&f)

Checks if unary predicate *f* returns true for all elements in the range [first, last).

> **Note**
>
> Complexity: At most *last* - *first* applications of the predicate *f*

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *all_of* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

The *all_of* algorithm returns a *bool* . The *all_of* algorithm returns true if the unary predicate *f* returns true for all elements in the range, false otherwise. It returns true if the range is empty.

hpx::any_of

Defined in header hpx/algorithm.hpp[730].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::all_of*
- *hpx::none_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
util::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::`**`any_of`**`(`*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f`)`

Checks if unary predicate *f* returns true for at least one element in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most *last* - *first* applications of the predicate *f*

Template Parameters

---

[730] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *any_of* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *any_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *any_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

template<typename **InIter**, typename **F**>
bool `hpx::any_of(InIter first, InIter last, F &&f)`

Checks if unary predicate *f* returns true for at least one element in the range [first, last).

Note

Complexity: At most *last* - *first* applications of the predicate *f*

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *any_of* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

The *any_of* algorithm returns a *bool* . The *any_of* algorithm returns true if the unary predicate *f* returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

hpx::none_of

Defined in header hpx/algorithm.hpp[731].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::all_of*
- *hpx::any_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
util::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::none_of`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Checks if unary predicate *f* returns true for no elements in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most *last* - *first* applications of the predicate *f*

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none_of* requires *F* to meet the requirements of *CopyConstructible*.

---

[731] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *none_of* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *none_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

template<typename **`InIter`**, typename **`F`**>
bool `hpx::`**`none_of`**`(`*InIter* first, *InIter* last, *F* &&f`)`

Checks if unary predicate *f* returns true for no elements in the range [first, last).

> **Note**
>
> Complexity: At most *last* - *first* applications of the predicate *f*

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *none_of* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

The *none_of* algorithm returns a *bool* . The *none_of* algorithm returns true if the unary predicate *f* returns true for no elements in the range, false otherwise. It returns true if the range is empty.

hpx::sort

Defined in header hpx/algorithm.hpp[732].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandomIt**, typename **Comp** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::*identity*>
void `hpx::sort`(*RandomIt* first, *RandomIt* last, *Comp* &&comp, *Proj* &&proj = *Proj*())

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The assignments in the parallel *sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- `RandomIt` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- `Comp` – The type of the function/function object to use (deduced).
- `Proj` – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `comp` – comp is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- `proj` – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *sort* algorithm returns *void*.

---

[732] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

template<typename **`ExPolicy`**, typename **`RandomIt`**, typename **`Comp`** = *hpx*::*parallel*::detail::less, typename **`Proj`** = *hpx*::*identity*>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **`hpx::sort`**(*ExPolicy* &&policy, *RandomIt* first, *RandomIt* last, *Comp* &&comp, *Proj* &&proj)

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **`RandomIt`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Comp`** – The type of the function/function object to use (deduced).
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`comp`** – comp is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **`proj`** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *sort* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::reduce_deterministic

Defined in header hpx/algorithm.hpp[733].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter**, typename **F**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::reduce_deterministic`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init, *F* &&f)

Returns GENERALIZED_SUM(f, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicate *f*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

---

[733] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
util::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`reduce_deterministic`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and

- 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **`ExPolicy`**, typename **`FwdIter`**>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::value_type>::type `hpx::reduce_deter`

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns T otherwise (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **FwdIter**, typename **F**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
T *hpx*::**`reduce_deterministic`**(*FwdIter* first, *FwdIter* last, *T* init, *F* &&f)

Returns GENERALIZED_SUM(f, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicate *f*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns *T*. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **`FwdIter`**, typename **`T`** = typename *std*::iterator_traits<*FwdIter*>::value_type>
T *hpx*::**`reduce_deterministic`**(*FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *T*. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **FwdIter**>
std::iterator_traits<*FwdIter*>::value_type `hpx`::**`reduce_deterministic`**(*FwdIter* first, *FwdIter* last)

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

`FwdIter` – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns *T* (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

hpx::find

Defined in header hpx/algorithm.hpp[734].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_if*
- *hpx::find_if_not*
- *hpx::find_end*
- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **`hpx::find`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &val)

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most last - first applications of the operator==().

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

---

[734] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **T** – The type of the value to find (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to

Returns

The *find* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

template<typename **InIter**, typename **T**>
InIter `hpx::`**find**(*InIter* first, *InIter* last, *T* const &val)

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

Note

Complexity: At most last - first applications of the operator==().

Template Parameters

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to find (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to

Returns

The *find* algorithm returns a *InIter*. The *find* algorithm returns the first element in the range [first,last) that is equal to *val*. If no such element in the range of [first,last) is equal to *val*, then the algorithm returns *last*.

hpx::find_if

Defined in header hpx/algorithm.hpp[735].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if_not*
- *hpx::find_end*
- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::find_if`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns true. Executed according to the policy.

The comparison operations in the parallel *find_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most last - first applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

---

[735] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate f, the algorithm returns *last*.

template<typename **`InIter`**, typename **`F`**>
InIter `hpx::`**`find_if`**(*InIter* first, *InIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns true.

Note

Complexity: At most last - first applications of the predicate.

Template Parameters

- **`InIter`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`f`** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if* algorithm returns a *InIter*. The *find_if* algorithm returns the first element in the range [first,last) that satisfies the predicate *f*. If no such element exists that satisfies the predicate f, the algorithm returns *last*.

hpx::find_if_not

Defined in header hpx/algorithm.hpp[736].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if*
- *hpx::find_end*
- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::find_if_not`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns false. Executed according to the policy.

The comparison operations in the parallel *find_if_not* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_if_not* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most last - first applications of the predicate.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`f`** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

---

[736] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if_not* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find_if_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate f, the algorithm returns *last*.

template<typename **FwdIter**, typename **F**>
FwdIter `hpx::`**`find_if_not`**(*FwdIter* first, *FwdIter* last, *F* &&f)

Returns the first element in the range [first, last) for which predicate *f* returns false.

Note

Complexity: At most last - first applications of the predicate.

Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

Returns

The *find_if_not* algorithm returns a *FwdIter*. The *find_if_not* algorithm returns the first element in the range [first, last) that does **not** satisfy the predicate *f*. If no such element exists that does not satisfy the predicate f, the algorithm returns *last*.

hpx::find_end

Defined in header hpx/algorithm.hpp[737].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if*
- *hpx::find_if_not*
- *hpx::find_first_of*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> `hpx::find_end`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate *op* to compare elements. Executed according to the policy.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find_end* is available if the user decides to provide the algorithm their own predicate *op*.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

---

[737] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`last2`** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **`op`** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_end* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> `hpx::`**`find_end`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the last subsequence of elements [first2, last2) found in the range [first, last). Elements are compared using *operator==*. Executed according to the policy.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_end* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`last2`** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_end* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`** = detail::equal_to>
FwdIter1 `hpx`::**`find_end`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns the last subsequence of elements [first2, last2) found in the range [first, last) using the given predicate *op* to compare elements.

This overload of *find_end* is available if the user decides to provide the algorithm their own predicate *op*.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *replace* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- **`last2`** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **`op`** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_end* algorithm returns a *FwdIter1*. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

template<typename **`FwdIter1`**, typename **`FwdIter2`**>
FwdIter1 `hpx::`**`find_end`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns the last subsequence of elements [first2, last2) found in the range [first, last). Elements are compared using *operator==*.

> **Note**
>
> Complexity: at most S*(N-S+1) comparisons where *S* = distance(first2, last2) and *N* = distance(first1, last1).

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`last2`** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_end* algorithm returns a *FwdIter1*. The *find_end* algorithm returns an iterator to the beginning of the last subsequence [first2, last2) in range [first, last). If the length of the subsequence [first2, last2) is greater than the length of the range [first1, last1), *last1* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last1* is also returned.

hpx::find_first_of

Defined in header hpx/algorithm.hpp[738].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find*
- *hpx::find_if*
- *hpx::find_if_not*
- *hpx::find_end*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> `hpx::`**`find_first_of`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses binary predicate *op* to compare elements. Executed according to the policy.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *find_first_of* is available if the user decides to provide the algorithm their own predicate *op*.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.

---

[738] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_first_of* algorithm returns a *hpx::future<FwdIter1>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter1* otherwise. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter1*> hpx::**find_first_of**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last)

Searches the range [first, last) for any elements in the range [s_first, s_last). Elements are compared using *operator==*. Executed according to the policy.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *find_first_of* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`s_first`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`s_last`** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_first_of* algorithm returns a *hpx::future<FwdIter1>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter1* otherwise. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`** = detail::equal_to>
FwdIter1 `hpx::`**`find_first_of`**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses binary predicate *op* to compare elements.

This overload of *find_first_of* is available if the user decides to provide the algorithm their own predicate *op*.

Note

Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **`s_first`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`s_last`** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **`op`** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

Returns

The *find_first_of* algorithm returns a *FwdIter1*. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

template<typename **`FwdIter1`**, typename **`FwdIter2`**>
FwdIter1 `hpx::`**`find_first_of`**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* s_first, *FwdIter2* s_last)

Searches the range [first, last) for any elements in the range [s_first, s_last). Elements are compared using *operator==*.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`s_first`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`s_last`** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The *find_first_of* algorithm returns a *FwdIter1*. The *find_first_of* algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last),

last is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *last* is also returned.

hpx::uninitialized_fill

Defined in header hpx/algorithm.hpp[739].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_fill_n*

template<typename **FwdIter**, typename **T**>
void hpx::**uninitialized_fill**(*FwdIter* first, *FwdIter* last, *T* const &value)

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *uninitialized_fill* algorithm returns nothing

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> hpx::**uninitialized_fill**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &value)

Copies the given *value* to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel *uninitialized_fill* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The initializations in the parallel *uninitialized_fill* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

[739] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: Linear in the distance between *first* and *last*

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`T`** – The type of the value to be assigned (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`value`** – The value to be assigned.

Returns

The *uninitialized_fill* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns nothing otherwise.

hpx::uninitialized_fill_n

Defined in header hpx/algorithm.hpp[740].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_fill*

template<typename **`FwdIter`**, typename **`Size`**, typename **`T`**>
FwdIter `hpx::`**`uninitialized_fill_n`**(*FwdIter* first, *Size* count, *T* const &value)

Copies the given *value* value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects.

Note

Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`T`** – The type of the value to be assigned (deduced).

---

[740] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`value`** – The value to be assigned.

Returns

The *uninitialized_fill_n* algorithm returns a returns *FwdIter*. The *uninitialized_fill_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Size`**, typename **`T`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::`**`uninitialized_fill_n`**(*ExPolicy* &&policy, *FwdIter* first, *Size* count, *T* const &value)

Copies the given *value* value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel *uninitialized_fill_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The initializations in the parallel *uninitialized_fill_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`T`** – The type of the value to be assigned (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`value`** – The value to be assigned.

Returns

The *uninitialized_fill_n* algorithm returns a *hpx::future<FwdIter>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns FwdIter otherwise. The *uninitialized_fill_n* algorithm returns the output iterator to the element in the range, one past the last element copied.

hpx::set_intersection

Defined in header hpx/algorithm.hpp[741].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter3*> **hpx::set_intersection**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (for *sequenced_task_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

---

[741] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter1`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_intersection* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_intersection* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter3* otherwise. The *set_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`FwdIter3`**, typename **`Pred`** = *hpx*::*parallel*::detail::less>
FwdIter3 **`hpx::set_intersection`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_intersection* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_intersection* algorithm returns a *FwdIter3*. The *set_intersection* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::fill

Defined in header hpx/algorithm.hpp[742].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::fill_n*

template<typename **ExPolicy**, typename **FwdIter**, typename **T**>
util::detail::algorithm_result_t<*ExPolicy*> `hpx::fill`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* value)

Assigns the given value to the elements in the range [first, last). Executed according to the policy.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

Returns

The *fill* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *void*.

template<typename **FwdIter**, typename **T**>
void `hpx::fill`(*FwdIter* first, *FwdIter* last, *T* value)

Assigns the given value to the elements in the range [first, last).

---

[742] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`T`** – The type of the value to be assigned (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`value`** – The value to be assigned.

Returns

The *fill* algorithm returns a *void*.

hpx::fill_n

Defined in header hpx/algorithm.hpp[743].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::fill*

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**, typename **T**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **`hpx::fill_n`**(*ExPolicy* &&policy, *FwdIter* first, *Size* count, *T* value)

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise. Executed according to the policy.

The comparisons in the parallel *fill_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *fill_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *count* assignments, for count > 0.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

---

[743] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- `FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- `Size` – The type of the argument specifying the number of elements to apply *f* to.
- `T` – The type of the value to be assigned (deduced).

Parameters

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `count` – Refers to the number of elements starting at *first* the algorithm will be applied to.
- `value` – The value to be assigned.

Returns

The *fill_n* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *difference_type* otherwise (where *difference_type* is defined by *void*.

template<typename `FwdIter`, typename `Size`, typename `T`>
FwdIter `hpx::fill_n`(*FwdIter* first, *Size* count, *T* value)

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

Note

Complexity: Performs exactly *count* assignments, for count > 0.

Template Parameters

- `FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- `Size` – The type of the argument specifying the number of elements to apply *f* to.
- `T` – The type of the value to be assigned (deduced).

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `count` – Refers to the number of elements starting at *first* the algorithm will be applied to.
- `value` – The value to be assigned.

Returns

The *fill_n* algorithm returns a *FwdIter*.

hpx::experimental::reduction_bit_xor

Defined in header hpx/algorithm.hpp[744].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_xor<*T*>> `hpx::experimental::`**`reduction_bit_xor`**`(`*T* &var`)`

The function template *reduction_bit_xor* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::bit_xor{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_bit_xor* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::bit_xor{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **`T`** – The value type to be used by the induction object.
- **`Op`** – The type of the binary function (object) used to perform the reduction operation.

Parameters

`var` – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing. The optional *identity* value is used for the reduction operation and defaults to `T()`.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_xor<*T*>> `hpx::experimental::`**`reduction_bit_xor`**`(`*T* &var, *T* const &identity`)`

---

[744] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::shift_left

Defined in header hpx/algorithm.hpp[745].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter**, typename **Size**>
FwdIter `hpx::shift_left`(*FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

- n), moves the element originally at position first + n + i to position first + i.

The assignment operations in the parallel *shift_left* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

Note

Complexity: At most (last - first) - n assignments.

Note

The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

Returns

The *shift_left* algorithm returns *FwdIter*. The *shift_left* algorithm returns an iterator to the end of the resulting range. Specifically: If *n* is 0 or *n* >= (last - first), does nothing and returns *last* and *first* respectively. Otherwise returns *first* + ((last - first) - n).

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*> `hpx::shift_left`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the beginning of the range. For every integer i in [0, last - first

---

[745] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- n), moves the element originally at position first + n + i to position first + i. Executed according to the policy.

The assignment operations in the parallel *shift_left* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift_left* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most (last - first) - n assignments.

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of positions to shift by.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`n`** – Refers to the number of positions to shift.

Returns

The *shift_left* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *shift_left* algorithm returns an iterator to the end of the resulting range. Specifically: If *n* is 0, does nothing and returns *last*. If *n* >= (last - first), does nothing and returns *first*. Otherwise returns *first* + ((last - first) - n).

hpx::swap_ranges

Defined in header hpx/algorithm.hpp[746].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter1**, typename **FwdIter2**>
FwdIter2 `hpx::swap_ranges`(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Exchanges elements between range [first1, last1) and another range starting at *first2*.

The swap operations in the parallel *swap_ranges* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear in the distance between *first1* and *last1*.

Template Parameters

- **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

Returns

The *swap_ranges* algorithm returns *FwdIter2*. The *swap_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::swap_ranges`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Exchanges elements between range [first1, last1) and another range starting at *first2*. Executed according to the policy.

The swap operations in the parallel *swap_ranges* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The swap operations in the parallel *swap_ranges* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

[746] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: Linear in the distance between *first1* and *last1*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the swap operations.
- **`FwdIter1`** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **`last1`** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

Returns

The *swap_ranges* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel_task_policy* and returns *FwdIter2* otherwise. The *swap_ranges* algorithm returns iterator to the element past the last element exchanged in the range beginning with *first2*.

hpx::experimental::reduction_plus

Defined in header hpx/algorithm.hpp[747].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::plus<*T*>> `hpx::experimental::`**`reduction_plus`**`(`*T* &var)

The function template *reduction_plus* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::plus{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_plus* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::plus{} operation until a single value remains, which is then assigned back to the live-out object.

---

[747] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **T** – The value type to be used by the induction object.
- **Op** – The type of the binary function (object) used to perform the reduction operation.

Parameters

var – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing. The optional *identity* value is used for the reduction operation and defaults to `T()`.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::plus<*T*>> `hpx::experimental::`**`reduction_plus`**(*T* &var, *T* const &identity)

hpx::merge

Defined in header hpx/algorithm.hpp[748].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::inplace_merge*

template<typename **ExPolicy**, typename **RandIter1**, typename **RandIter2**, typename **RandIter3**, typename **Comp** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *RandIter3*> `hpx::`**`merge`**(*ExPolicy* &&policy, *RandIter1* first1, *RandIter1* last1, *RandIter2* first2, *RandIter2* last2, *RandIter3* dest, *Comp* &&comp = *Comp*())

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at *dest*. The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges. Executed according to the policy.

---

[748] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *merge* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison *comp* and each projection.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`RandIter1`** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of a random access iterator.
- **`RandIter2`** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of a random access iterator.
- **`RandIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Comp`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **`last1`** – Refers to the end of the first range of elements the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **`last2`** – Refers to the end of the second range of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`comp`** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```
  bool comp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter1* and *RandIter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *merge* algorithm returns a *hpx::future<RandIter3>* > if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandIter3* otherwise. The *merge* algorithm returns the destination iterator to the end of the *dest* range.

template<typename **RandIter1**, typename **RandIter2**, typename **RandIter3**, typename **Comp** = *hpx*::*parallel*::detail::less>
RandIter3 **hpx::merge**(*RandIter1* first1, *RandIter1* last1, *RandIter2* first2, *RandIter2* last2, *RandIter3* dest, *Comp* &&comp = *Comp*())

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at *dest*. The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

Note

Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison *comp* and each projection.

Template Parameters

- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```
  bool comp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter1* and *RandIter2* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *merge* algorithm returns a *RandIter3*. The *merge* algorithm returns the destination iterator to the end of the *dest* range.

hpx::inplace_merge

Defined in header hpx/algorithm.hpp[749].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::merge*

template<typename **ExPolicy**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **hpx::inplace_merge**(*ExPolicy* &&policy, *RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. Executed according to the policy.

The assignments in the parallel *inplace_merge* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *inplace_merge* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs O(std::distance(first, last)) applications of the comparison *comp* and each projection.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.

---

[749] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.
- **`comp`** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```
  bool comp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *inplace_merge* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns void otherwise. The *inplace_merge* algorithm returns the source iterator *last*.

template<typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
void *hpx*::**inplace_merge**(*RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

Note

Complexity: Performs O(std::distance(first, last)) applications of the comparison *comp* and each projection.

Template Parameters

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *inplace_merge* requires *Comp* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`first`** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **`middle`** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **`last`** – Refers to the end of the second sorted range the algorithm will be applied to.
- **`comp`** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```
  bool comp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *RandIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*

Returns

The *inplace_merge* algorithm returns a *void*. The *inplace_merge* algorithm returns the source iterator *last*.

hpx::equal

Defined in header hpx/algorithm.hpp[750].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>
util::detail::algorithm_result_t<*ExPolicy*, bool> hpx::**equal**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to the policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(min(*last1* - *first1*, *last2* - *first2*)) applications of the predicate *op*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

---

[750] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**>
util::detail::algorithm_result_t<*ExPolicy*, bool> `hpx`::**`equal`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(min(*last1* - *first1*, *last2* - *first2*)) applications of the predicate *std::equal_to*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>
util::detail::algorithm_result_t<*ExPolicy*, bool> `hpx`::**`equal`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(min(*last1* - *first1*, *last2* - *first2*)) applications of the predicate *op*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**>
util::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::`**`equal`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2)

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to policy.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most *last1* - *first1* applications of the predicate *op*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *equal* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`** = detail::equal_to>
bool `hpx::`**`equal`**`(`*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *op*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *bool* . The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **`FwdIter1`**, typename **`FwdIter2`**>
bool `hpx::`**`equal`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2)

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

Note

Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *std::equal_to*.

Note

The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

Returns

The *equal* algorithm returns a *bool* . The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = detail::equal_to>
bool `hpx::`**`equal`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *Pred* &&op = *Pred*())

Returns true if the range [first1, last1) is equal to the range [first2, first2 + (last1 - first1)), and false otherwise.

> **Note**
>
> Complexity: At most *last1 - first1* applications of the predicate *op*.

> **Note**
>
> The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *equal* algorithm returns a *bool* . The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

hpx::experimental::reduction_bit_or

Defined in header hpx/algorithm.hpp[751].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_or<*T*>> `hpx::experimental::`**`reduction_bit_or`**`(`*T* &var)

The function template *reduction_bit_or* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::bit_or{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_bit_or* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::bit_or{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

Note

In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **`T`** – The value type to be used by the induction object.
- **`Op`** – The type of the binary function (object) used to perform the reduction operation.

Parameters

`var` – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing. The optional *identity* value is used for the reduction operation and defaults to `T()`.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_or<*T*>> `hpx::experimental::`**`reduction_bit_or`**`(`*T* &var, *T* const &identity)

---

[751] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::experimental::for_loop

Defined in header hpx/algorithm.hpp[752].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::experimental::for_loop_strided*
- *hpx::experimental::for_loop_n*
- *hpx::experimental::for_loop_n_strided*

template<typename **I**, typename ...**Args**>
void `hpx::experimental::`**`for_loop`**(*std*::decay_t<*I*> first, *I* last, *Args*&&... args)

The for_loop implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying *hpx::execution::seq* as the execution policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last* - *first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

Note

As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

[752] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

Template Parameters

- `I` – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- `Args` – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `args` – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

  ```
  <ignored> pred(I const& a, ...);
  ```

  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

template<typename **ExPolicy**, typename **I**, typename ...**Args**>
auto `hpx::experimental::`**`for_loop`**(*ExPolicy* &&policy, *std*::decay_t<*I*> first, *I* last, *Args*&&... args)

The for_loop implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last - first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

Note

As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

Note

The order of the elements of the input sequence is important for determining ordinal position of an application of *f*, even though the applications themselves may be unordered.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **`I`** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **`Args`** – A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`args`** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

  ```
  <ignored> pred(I const& a, ...);
  ```

  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Returns

The *for_loop* algorithm returns a *hpx::future<void>* if the execution policy is of type *hpx::execution::sequenced_task_policy* or *hpx::execution::parallel_task_policy* and returns *void* otherwise.

hpx::experimental::for_loop_strided

Defined in header hpx/algorithm.hpp[753].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::experimental::for_loop*
- *hpx::experimental::for_loop_n*
- *hpx::experimental::for_loop_n_strided*

template<typename **I**, typename **S**, typename ...**Args**>
void `hpx::experimental::for_loop_strided`(*std*::decay_t<*I*> first, *I* last, *S* stride, *Args*&&... args)

The for_loop_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying *hpx::execution::seq* as the execution policy.

Requires: *I* shall be an integral type or meet the requirements of an input iterator type. The *args* parameter pack shall have at least one element, comprising objects returned by invocations of *reduction* and/or *induction* function templates followed by exactly one element invocable element-access function, *f*. *f* shall meet the requirements of *MoveConstructible*.

Effects: Applies *f* to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the *args* parameter pack. The length of the input sequence is *last* - *first*.

The first element in the input sequence is specified by *first*. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the *args* parameter pack excluding *f*, an additional argument is passed to each application of *f* as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of *f* in the input sequence.

Complexity: Applies *f* exactly once for each element of the input sequence.

Remarks: If *f* returns a result, the result is ignored.

Note

As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

The *for_loop_n_strided* algorithm returns a *hpx::future<void>* if the execution policy is of type *hpx::execution::sequenced_task_policy* or *hpx::execution::parallel_task_policy* and returns *void* otherwise.

hpx::replace

Defined in header hpx/algorithm.hpp[756].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::replace_if*
- *hpx::replace_copy*
- *hpx::replace_copy_if*

template<typename **InIter**, typename **T** = typename *std*::iterator_traits<*InIter*>::value_type>
void *hpx*::**replace**(*InIter* first, *InIter* last, *T* const &old_value, *T* const &new_value)

Replaces all elements satisfying specific criteria with *new_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: *it == old_value

The assignments in the parallel *replace* algorithm execute in sequential order in the calling thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`T`** – The type of the old and new values to replace (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

---

[756] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`old_value`** – Refers to the old value of the elements to replace.
- **`new_value`** – Refers to the new value to use as the replacement.

Returns

The *replace* algorithm returns a *void*.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`T`** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, void> **`hpx::replace`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &old_value, *T* const &new_value)

Replaces all elements satisfying specific criteria with *new_value* in the range [first, last). Executed according to the policy.

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: *it == old_value

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last - first* assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`T`** – The type of the old and new values to replace (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`old_value`** – Refers to the old value of the elements to replace.
- **`new_value`** – Refers to the new value to use as the replacement.

Returns

The *replace* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::replace_if

Defined in header hpx/algorithm.hpp[757].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::replace*
- *hpx::replace_copy*
- *hpx::replace_copy_if*

template<typename **Iter**, typename **Pred**, typename **T** = typename *std*::iterator_traits<*Iter*>::value_type>
void *hpx*::**replace_if**(*Iter* first, *Iter* last, *Pred* &&pred, *T* const &new_value)

Replaces all elements satisfying specific criteria (for which predicate *pred* returns true) with *new_value* in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel *replace_if* algorithm execute in sequential order in the calling thread.

Note

Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.

---

[757] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`new_value`** – Refers to the new value to use as the replacement.

Returns

The *replace_if* algorithm returns *void*.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Pred`**, typename **`T`** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, void> **`hpx::replace_if`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred, *T* const &new_value)

Replaces all elements satisfying specific criteria (for which predicate *f* returns true) with *new_value* in the range [first, last). Executed according to the policy.

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel *replace_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* applications of the predicate.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **`T`** – The type of the new values to replace (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

- **`new_value`** – Refers to the new value to use as the replacement.

Returns

The *replace_if* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::replace_copy

Defined in header hpx/algorithm.hpp[758].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **OutIter**, typename **T** = typename *std*::iterator_traits<*OutIter*>::value_type>
OutIter `hpx::`**`replace_copy`**(*InIter* first, *InIter* last, *OutIter* dest, *T* const &old_value, *T* const &new_value)

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new_value*.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value

The assignments in the parallel *replace_copy* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last - first* applications of the predicate.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`T`** – The type of the old and new values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`old_value`** – Refers to the old value of the elements to replace.

---

- **`new_value`** – Refers to the new value to use as the replacement.

Returns

The *replace_copy* algorithm returns an *OutIter* The *replace_copy* algorithm returns the Iterator to the element past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`T`** = typename *std*::iterator_traits<*FwdIter2*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> **`hpx::replace_copy`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* const &old_value, *T* const &new_value)

Copies the all elements from the range [first, last) to another range beginning at *dest* replacing all elements satisfying a specific criteria with *new_value*. Executed according to the policy.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value

The assignments in the parallel *replace_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *replace_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last - first* applications of the predicate.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`T`** – The type of the old and new values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`old_value`** – Refers to the old value of the elements to replace.
- **`new_value`** – Refers to the new value to use as the replacement.

Returns

The *replace_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *replace_copy* algorithm returns the Iterator to the element past the last element copied.

hpx::replace_copy_if

Defined in header hpx/algorithm.hpp[759].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *replace_copy_if* requires *Pred* to meet the requirements of *CopyConstructible*. (deduced).
- **T** – The type of the new values to replace (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.
- **new_value** – Refers to the new value to use as the replacement.

Returns

The *replace_copy_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *replace_copy_if* algorithm returns the iterator to the element in the destination range, one past the last element copied.

hpx::inclusive_scan

Defined in header hpx/algorithm.hpp[760].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **OutIter**>
OutIter `hpx::`**`inclusive_scan`**(*InIter* first, *InIter* last, *OutIter* dest)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, *first, …, *(first + (i - result))).

The reduce operations in the parallel *inclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

---

[760] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: O(*last* - *first*) applications of the predicate *op*, here std::plus<>().

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, . . . , aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, . . . , aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, . . . , aN) where 1 < K+1 = M <= N.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *inclusive_scan* algorithm returns *OutIter*. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::`**`inclusive_scan`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, *first, . . . , *(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*, here std::plus<>().

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aK)
    - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`InIter`**, typename **`OutIter`**, typename **`Op`**>
OutIter `hpx::`**`inclusive_scan`**(*InIter* first, *InIter* last, *OutIter* dest, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, …, *(first + (i - result))).

The reduce operations in the parallel *inclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *inclusive_scan* algorithm returns *OutIter*. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Op**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::inclusive_scan`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, …, *(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Op`** – The type of the binary function object used for the reduction operation.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **Op**, typename **T**>
OutIter `hpx::inclusive_scan`(*InIter* first, *InIter* last, *OutIter* dest, *Op* &&op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, …, *(first + (i - result))).

The reduce operations in the parallel *inclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **`init`** – The initial value for the generalized sum.

Returns

The *inclusive_scan* algorithm returns *OutIter*. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Op`**, typename **`T`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx`::**`inclusive_scan`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, …, *(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Op`** – The type of the binary function object used for the reduction operation.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.
- **`init`** – The initial value for the generalized sum.

Returns

The *inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::uninitialized_copy

Defined in header hpx/algorithm.hpp[761].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_copy_n*

template<typename **`InIter`**, typename **`FwdIter`**>
FwdIter `hpx::`**`uninitialized_copy`**(*InIter* first, *InIter* last, *FwdIter* dest)

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized_copy* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

---

[761] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_copy* algorithm returns *FwdIter*. The *uninitialized_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::`**`uninitialized_copy`**`(`*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest`)`

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the copy operation, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_copy* algorithm returns a *hpx::future<FwdIter2>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *uninitialized_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::uninitialized_copy_n

Defined in header hpx/algorithm.hpp[762].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_copy*

template<typename **`InIter`**, typename **`Size`**, typename **`FwdIter`**>
FwdIter `hpx::`**`uninitialized_copy_n`**(*InIter* first, *Size* count, *FwdIter* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized_copy_n* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

---

[762] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Returns

The *uninitialized_copy_n* algorithm returns a returns *FwdIter*. The *uninitialized_copy_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **Size**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::uninitialized_copy_n`(*ExPolicy* &&policy, *FwdIter1* first, *Size* count, *FwdIter2* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel *uninitialized_copy_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_copy_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply *f* to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_copy_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *uninitialized_copy_n* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::experimental::reduction_bit_and

Defined in header hpx/algorithm.hpp[763].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_and<*T*>> `hpx::experimental::`**`reduction_bit_and`**(*T* &var)

The function template *reduction_bit_and* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::bit_and{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_bit_and* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::bit_and{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **`T`** – The value type to be used by the induction object.
- **`Op`** – The type of the binary function (object) used to perform the reduction operation.

Parameters

`var` – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing. The optional *identity* value is used for the reduction operation and defaults to `~T()`.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::bit_and<*T*>> `hpx::experimental::`**`reduction_bit_and`**(*T* &var, *T* const &identity)

---

[763] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::shift_right

Defined in header hpx/algorithm.hpp[764].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`FwdIter`**, typename **`Size`**>
FwdIter `hpx::`**`shift_right`**(*FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

- n + i.

The assignment operations in the parallel *shift_right* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: At most (last - first) - n assignments.

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of positions to shift by.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`n`** – Refers to the number of positions to shift.

Returns

The *shift_right* algorithm returns *FwdIter*. The *shift_right* algorithm returns an iterator to the beginning of the resulting range. Specifically: If *n* is 0 or *n* >= (last - first), does nothing and returns *first* and *last* respectively. Otherwise returns *first* + n.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Size`**>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*> `hpx::`**`shift_right`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Size* n)

Shifts the elements in the range [first, last) by n positions towards the end of the range. For every integer i in [0, last - first - n), moves the element originally at position first + i to position first

---

[764] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- n + i. Executed according to the policy.

The assignment operations in the parallel *shift_right* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignment operations in the parallel *shift_right* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most (last - first) - n assignments.

Note

The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of positions to shift by.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`n`** – Refers to the number of positions to shift.

Returns

The *shift_right* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *shift_right* algorithm returns an iterator to the beginning of the resulting range. Specifically: If *n* is 0, does nothing and returns *first*. If *n* >= (last - first), does nothing and returns *last*. Otherwise returns *first* + n.

hpx::reduce

Defined in header hpx/algorithm.hpp[765].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter**, typename **F**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::reduce`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init, *F* &&f)

Returns GENERALIZED_SUM(f, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicate *f*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

---

[765] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **ExPolicy**, typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
util::detail::algorithm_result_t<*ExPolicy*, *T*> `hpx::`**`reduce`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **`ExPolicy`**, typename **`FwdIter`**>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, typename *std*::iterator_traits<*FwdIter*>::value_type>::type **`hpx::reduce`**(*ExPol*
&&po
icy,
FwdIt
first,
FwdIt
last)

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the operator+().

Note

The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns T otherwise (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **FwdIter**, typename **F**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
T `hpx::`**`reduce`**`(`*FwdIter* first, *FwdIter* last, *T* init, *F* &&f`)`

Returns GENERALIZED_SUM(f, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the predicate *f*.

Note

GENERALIZED_SUM(op, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, …, bK), GENERALIZED_SUM(op, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *reduce* requires *F* to meet the requirements of *CopyConstructible*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to any of those types.

Returns

The *reduce* algorithm returns *T*. The *reduce* algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

template<typename **`FwdIter`**, typename **`T`** = typename *std*::iterator_traits<*FwdIter*>::value_type>
T `hpx::`**`reduce`**(*FwdIter* first, *FwdIter* last, *T* init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:
  - b1, …, bN may be any permutation of a1, …, aN and
  - 1 < K+1 = M <= N.

Template Parameters

- **`FwdIter`** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`init`** – The initial value for the generalized sum.

Returns

The *reduce* algorithm returns a *T*. The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename **`FwdIter`**>
std::iterator_traits<*FwdIter*>::value_type `hpx::`**`reduce`**(*FwdIter* first, *FwdIter* last)

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between *reduce* and *accumulate* is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note

Complexity: O(*last* - *first*) applications of the operator+().

Note

The type of the initial value (and the result type) *T* is determined from the value_type of the used *FwdIter*.

Note

GENERALIZED_SUM(+, a1, …, aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN)), where:

- b1, …, bN may be any permutation of a1, …, aN and
- 1 < K+1 = M <= N.

Template Parameters

FwdIter – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reduce* algorithm returns *T* (where T is the value_type of *FwdIter*). The *reduce* algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

hpx::lexicographical_compare

Defined in header hpx/algorithm.hpp[766].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter1**, typename **InIter2**, typename **Pred** = *hpx*::*parallel*::detail::less>
bool *hpx*::**lexicographical_compare**(*InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred)

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical_compare* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

Note

Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically *less* or *greater* than the other
- If one range is a prefix of another, the shorter range is lexicographically *less* than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
- An empty range is lexicographically *less* than any non-empty range

---

[766] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- Two empty ranges are lexicographically *equal*

Template Parameters

- **`InIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **`InIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`pred`** – Refers to the comparison function that the first and second ranges will be applied to

Returns

The *lexicographically_compare* algorithm returns a returns *bool* if the execution policy object is not passed in. The *lexicographically_compare* algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> `hpx::`**`lexicographical_compare`**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&pred)

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel *lexicographical_compare* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *lexicographical_compare* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

Note

Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically *less* or *greater* than the other
- If one range is a prefix of another, the shorter range is lexicographically *less* than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
- An empty range is lexicographically *less* than any non-empty range
- Two empty ranges are lexicographically *equal*

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *lexicographical_compare* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`pred`** – Refers to the comparison function that the first and second ranges will be applied to

Returns

The *lexicographically_compare* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *lexico-*

graphically_compare algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

hpx::set_difference

Defined in header hpx/algorithm.hpp[767].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter3*> `hpx::set_difference`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

Equivalent elements are treated individually, that is, if some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly std::max(m-n, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (for *sequenced_task_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **`FwdIter1`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

---

[767] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a output iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_difference* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter3* otherwise. The *set_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`FwdIter3`**, typename **`Pred`** = *hpx*::*parallel*::detail::less>
FwdIter3 `hpx::`**`set_difference`**`(`*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*.

Equivalent elements are treated individually, that is, if some element is found *m* times in [first1, last1) and *n* times in [first2, last2), it will be copied to *dest* exactly std::max(m-n, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- `FwdIter1` – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- `FwdIter2` – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- `FwdIter3` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a output iterator.
- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_difference* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- `first1` – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `last1` – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- `first2` – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- `last2` – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `op` – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_difference* algorithm returns a *FwdIter3*. The *set_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::experimental::induction

Defined in header hpx/algorithm.hpp[768].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

---

[768] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

constexpr *hpx*::*parallel*::detail::induction_stride_helper<*T*> `hpx::experimental::`**`induction`**(*T* &&value, *std*::size_t stride)

The function template returns an induction object of unspecified type having a value type and encapsulating an initial *value* of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence *S* computes an induction value from an induction variable and ordinal position *p* within *S* by the formula i + p * stride if a stride was specified or i + p otherwise. This induction value is passed to the element access function.

If the *value* argument to *induction* is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of i + n * stride to the live-out object upon return, where *n* is the number of elements in the input range.

Template Parameters

`T` – The value type to be used by the induction object.

Parameters

- **`value`** – [in] The initial value to use for the induction object
- **`stride`** – [in] The (optional) stride to use for the induction object (default: 1)

Returns

This returns an induction object with value type *T*, initial *value*, and (if specified) *stride*. If *T* is a lvalue of non-const type, *value* is used as the live-out object for the induction object; otherwise there is no live-out object.

template<typename **`T`**>
constexpr *hpx*::*parallel*::detail::induction_helper<*T*> `hpx::experimental::`**`induction`**(*T* &&value)

hpx::transform_inclusive_scan

Defined in header hpx/algorithm.hpp[769].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`InIter`**, typename **`OutIter`**, typename **`BinOp`**, typename **`UnOp`**>
OutIter `hpx::`**`transform_inclusive_scan`**(*InIter* first, *InIter* last, *OutIter* dest, *BinOp* &&binary_op, *UnOp* &&unary_op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), …, conv(*(first + (i - result)))).

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum.

---

[769] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`BinOp`** – The type of *binary_op*.
- **`UnOp`** – The type of *unary_op*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`binary_op`** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- **`unary_op`** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_inclusive_scan* algorithm returns a returns *OutIter*. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`BinOp`**, typename **`UnOp`**>
parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type `hpx::`**`transform_inclusive_scan`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *BinOp* &&binary_op, *UnOp* &&unary_op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), …, conv(*(first + (i - result)))). Executed according to the policy.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum.

> **Note**
>
> Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

> **Note**
>
> GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:
>
> - a1 when N is 1
> - op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`BinOp`** – The type of *binary_op*.
- **`UnOp`** – The type of *unary_op*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **`dest`** – Refers to the beginning of the destination range.
- **`binary_op`** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- **`unary_op`** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`InIter`**, typename **`OutIter`**, typename **`BinOp`**, typename **`UnOp`**, typename **`T`** = typename *std*::iterator_traits<*InIter*>::value_type>
OutIter `hpx::`**`transform_inclusive_scan`**(*InIter* first, *InIter* last, *OutIter* dest, *BinOp* &&binary_op, *UnOp* &&unary_op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, conv(*first), …, conv(*(first + (i - result)))).

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum. If *binary_op* is not mathematically associative, the behavior of *transform_inclusive_scan* may be non-deterministic.

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`BinOp`** – The type of *binary_op*.

- **UnOp** – The type of *unary_op*.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary_op** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- **unary_op** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.
- **init** – The initial value for the generalized sum.

Returns

The *transform_inclusive_scan* algorithm returns a returns *OutIter*. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **BinOp**, typename **UnOp**, typename **T** = typename *std*::iterator_traits<*FwdIter1*>::value_type>
parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type hpx::**transform_inclusive_scan**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *BinOp* &&binary_op, *UnOp* &&unary_op, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, conv(*first), …, conv(*(first + (i - result)))). Executed according to the policy.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum. If *binary_op* is not mathematically associative, the behavior of *transform_inclusive_scan* may be non-deterministic.

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`BinOp`** – The type of *binary_op*.
- **`UnOp`** – The type of *unary_op*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`binary_op`** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.
- **`unary_op`** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.
- **`init`** – The initial value for the generalized sum.

Returns

The *transform_inclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::experimental::sort_by_key

Defined in header hpx/algorithm.hpp[770].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **KeyIter**, typename **ValueIter**, typename **Compare** = detail::less>
util::detail::algorithm_result_t<*ExPolicy*, sort_by_key_result<*KeyIter*, *ValueIter*>> `hpx::experimental::sort_by_key`(*ExPolicy* &&policy, *KeyIter* key_first, *KeyIter* key_last, *ValueIter* value_first, *Compare* &&comp = *Compare*())

Sorts one range of data using keys supplied in another range. The key elements in the range [key_first, key_last) are sorted in ascending order with the corresponding elements in the value range moved to follow the sorted order. The algorithm is not stable, the order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, *(i + n), *i) == false.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **KeyIter** – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

---

[770] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`ValueIter`** – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Compare`** – The type of the function/function object to use (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`key_first`** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **`key_last`** – Refers to the end of the sequence of key elements the algorithm will be applied to.
- **`value_first`** – Refers to the beginning of the sequence of value elements the algorithm will be applied to, the range of elements must match [key_first, key_last)
- **`comp`** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

Returns

The *sort_by_key* algorithm returns a hpx::future<*sort_by_key_result*<*KeyIter,ValueIter*>> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *otherwise*. The algorithm returns a pair holding an iterator pointing to the first element after the last element in the input key sequence and an iterator pointing to the first element after the last element in the input value sequence.

hpx::rotate

Defined in header hpx/algorithm.hpp[771].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::rotate_copy*

template<typename **`FwdIter`**>
FwdIter **`hpx::rotate`**(*FwdIter* first, *FwdIter* new_first, *FwdIter* last)

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel *rotate* algorithm execute in sequential order in the calling thread.

Note

Complexity: Linear in the distance between *first* and *last*.

---

[771] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

Template Parameters

`FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `new_first` – Refers to the element that should appear at the beginning of the rotated range.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *rotate* algorithm returns a FwdIter. The *rotate* algorithm returns the iterator to the new location of the element pointed by first,equal to first + (last - new_first).

template<typename **ExPolicy**, typename **FwdIter**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::rotate`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* new_first, *FwdIter* last)

Performs a left rotation on a range of elements. Specifically, *rotate* swaps the elements in the range [first, last) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element. Executed according to the policy.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *rotate* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Linear in the distance between *first* and *last*.

> **Note**
>
> The type of dereferenced *FwdIter* must meet the requirements of *MoveAssignable* and *MoveConstructible*.

Template Parameters

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`new_first`** – Refers to the element that should appear at the beginning of the rotated range.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *rotate* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *rotate* algorithm returns the iterator equal to first + (last - new_first).

hpx::rotate_copy

Defined in header hpx/algorithm.hpp[772].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::rotate*

template<typename **FwdIter**, typename **OutIter**>
OutIter `hpx::`**`rotate_copy`**(*FwdIter* first, *FwdIter* new_first, *FwdIter* last, *OutIter* dest_first)

Copies the elements from the range [first, last), to another range beginning at *dest_first* in such a way, that the element *new_first* becomes the first element of the new range and *new_first* - 1 becomes the last element.

The assignments in the parallel *rotate_copy* algorithm execute in sequential order in the calling thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`OutIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a output iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`new_first`** – Refers to the element that should appear at the beginning of the rotated range.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest_first`** – Refers to the begin of the destination range.

Returns

The *rotate_copy* algorithm returns a output iterator, The *rotate_copy* algorithm returns the output iterator to the element past the last element copied.

---

[772] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::rotate_copy`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* new_first, *FwdIter1* last, *FwdIter2* dest_first)

Copies the elements from the range [first, last), to another range beginning at *dest_first* in such a way, that the element *new_first* becomes the first element of the new range and *new_first* - 1 becomes the last element. Executed according to the policy.

The assignments in the parallel *rotate_copy* algorithm execute in sequential order in the calling thread.

The assignments in the parallel *rotate_copy* algorithm execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_first** – Refers to the begin of the destination range.

Returns

The *rotate_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *parallel_task_policy* and returns FwdIter2 otherwise. The *rotate_copy* algorithm returns the output iterator to the element past the last element copied.

hpx/parallel/algorithms/iota.hpp

Defined in header hpx/parallel/algorithms/iota.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

template<typename **FwdIter**, typename **Sent**, typename **T**>
void **iota**(*FwdIter* first, *Sent* last, *T* value)

Fills the range [first, last) with sequentially increasing values, starting with *value* and repetitively evaluating `++value`.

The assignments in the *iota* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Exactly *std::distance(first, last)* assignments and increments.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input or output iterator.
- **`Sent`** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **`T`** – The type of the value to be assigned (deduced). This type must be weakly incrementable.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`value`** – The value to be stored in the first element.

Returns

The *iota* algorithm returns *void*.

template<typename **ExPolicy**, typename **FwdIter**, typename **Sent**, typename **T**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> **iota**(*ExPolicy* &&policy, *FwdIter* first, *Sent* last, *T* value)

Fills the range [first, last) with sequentially increasing values, starting with *value* and repetitively evaluating `++value`.

The assignments in the parallel *iota* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *iota* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly *std::distance(first, last)* assignments and increments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Sent`** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **`T`** – The type of the value to be assigned (deduced). This type must be weakly incrementable.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`value`** – The value to be stored in the first element.

Returns

The *iota* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::transform_exclusive_scan

Defined in header hpx/algorithm.hpp[773].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`InIter`**, typename **`OutIter`**, typename **`BinOp`**, typename **`UnOp`**, typename **`T`** = typename *std*::iterator_traits<*InIter*>::value_type>
OutIter `hpx`::**`transform_exclusive_scan`**(*InIter* first, *InIter* last, *OutIter* dest, *T* init, *BinOp* &&binary_op, *UnOp* &&unary_op)

Transforms each element in the range [first, last) with *unary_op*, then computes an exclusive prefix sum operation using *binary_op* over the resulting range, with *init* as the initial value, and writes the results to the range beginning at *dest*. "exclusive" means that the i-th input element is not included in the i-th sum. Formally, assigns through each iterator i in [dest, d_first + (last - first)) the value of the generalized noncommutative sum of init, unary_op(*j)… for every j in [first, first + (i - d_first)) over binary_op, where generalized noncommutative sum GNSUM(op, a1, …, a N) is defined as follows:

- if N=1, a1

---

[773] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- if N > 1, op(GNSUM(op, a1, …, aK), GNSUM(op, aM, …, aN)) for any K where 1 < K+1 = M <= N In other words, the summation operations may be performed in arbitrary order, and the behavior is nondeterministic if *binary_op* is not associative.

The reduce operations in the parallel *transform_exclusive_scan* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither *unary_op* nor *binary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of transform_exclusive_scan may be non-deterministic for a non-associative predicate.

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`BinOp`** – The type of *binary_op*.
- **`UnOp`** – The type of *unary_op*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`init`** – The initial value for the generalized sum.
- **`binary_op`** – Binary *FunctionObject* that will be applied to the result of *unary_op*, the results of other *binary_op*, and *init*.
- **`unary_op`** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_exclusive_scan* algorithm returns a returns *OutIter*. The *transform_exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **BinOp**, typename **UnOp**, typename **T** = typename *std*::iterator_traits<*FwdIter1*>::value_type>
parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type `hpx::transform_exclusive_scan`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* init, *BinOp* &&binary_op, *UnOp* &&unary_op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), …, conv(*(first + (i - result) - 1))). Executed according to the policy.

The reduce operations in the parallel *transform_exclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_exclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *unary_op* nor *binary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The behavior of transform_exclusive_scan may be non-deterministic for a non-associative predicate.

Note

Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`BinOp`** – The type of *binary_op*.
- **`UnOp`** – The type of *unary_op*.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`init`** – The initial value for the generalized sum.
- **`binary_op`** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init*.
- **`unary_op`** – Unary *FunctionObject* that will be applied to each element of the input range. The return type must be acceptable as input to *binary_op*.

Returns

The *transform_exclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *transform_exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::generate

Defined in header hpx/algorithm.hpp[774].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::generate_n*

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::generate`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Assign each element in range [*first*, *last*) a value generated by the given function object *f*. Executed according to the policy.

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

---

[774] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *generate* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – generator function that will be called. signature of function should be equivalent to the following:

  ```
  Ret fun();
  ```

  The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

Returns

The *generate* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise.

template<typename **FwdIter**, typename **F**>
void hpx::**generate**(*FwdIter* first, *FwdIter* last, *F* &&f)

Assign each element in range [*first*, *last*) a value generated by the given function object *f*.

Note

Complexity: Exactly *distance(first, last)* invocations of *f* and assignments.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – generator function that will be called. signature of function should be equivalent to the following:

  ```
  Ret fun();
  ```

  The type *Ret* must be such that an object of type *FwdIter* can be dereferenced and assigned a value of type *Ret*.

Returns

The *generate* algorithm returns void.

hpx::generate_n

Defined in header hpx/algorithm.hpp[775].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::generate*

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**, typename **F**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::generate_n`(*ExPolicy* &&policy, *FwdIter* first, *Size* count, *F* &&f)

Assigns each element in range [*first*, *first+)* a value generated by the given function object *f*. Executed according to the policy.

The assignments in the parallel *generate_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *generate_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Exactly *count* invocations of *f* and assignments, for count > 0.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`Size`** – The type of a non-negative integral value specifying the number of items to iterate over.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

---

[775] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **`f`** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

```
Ret fun();
```

  The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

Returns

The *generate_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. *generate_n* algorithm returns iterator one past the last element assigned if count>0, first otherwise.

template<typename **`FwdIter`**, typename **`Size`**, typename **`F`**>
FwdIter `hpx::`**`generate_n`**`(`*FwdIter* first, *Size* count, *F* &&f`)`

Assigns each element in range [*first*, *first+)* a value generated by the given function object *f*.

Note

Complexity: Exactly *count* invocations of *f* and assignments, for count > 0.

Template Parameters

- **`Size`** – The type of a non-negative integral value specifying the number of items to iterate over.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *equal* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **`f`** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

```
Ret fun();
```

  The type *Ret* must be such that an object of type *OutputIt* can be dereferenced and assigned a value of type *Ret*.

Returns

The *generate_n* algorithm returns a *FwdIter*. *generate_n* algorithm returns iterator one past the last element assigned if count>0, first otherwise.

hpx::adjacent_difference

Defined in header hpx/algorithm.hpp[776].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **FwdIter1**, typename **FwdIter2**>
FwdIter2 `hpx::adjacent_difference(`*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first.

> **Note**
>
> Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- `FwdIter1` – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- `FwdIter2` – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- `first` – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- `dest` – Refers to the beginning of the sequence of elements the results will be assigned to.

Returns

The *adjacent_difference* algorithm returns a *FwdIter2*. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::adjacent_difference(`*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first. Executed according to the policy.

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

---

[776] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1` – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- `FwdIter2` – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- `dest` – Refers to the beginning of the sequence of elements the results will be assigned to.

Returns

The *adjacent_difference* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Op**>
FwdIter2 `hpx::adjacent_difference`(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first

Note

Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- `FwdIter1` – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- `FwdIter2` – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.
- `Op` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent_difference* requires *Op* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **`op`** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

  ```
  bool op(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter1* can be dereferenced and then implicitly converted to the dereferenced type of *dest*.

Returns

The *adjacent_difference* algorithm returns *FwdIter2*. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Op`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx`::**`adjacent_difference`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Op* &&op)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The difference operations in the parallel *adjacent_difference* invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *adjacent_difference* requires *Op* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **op** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

  ```
  bool op(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter1* can be dereferenced and then implicitly converted to the dereferenced type of *dest*.

Returns

The *adjacent_difference* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *adjacent_difference* algorithm returns an iterator to the element past the last element written.

hpx::remove

Defined in header hpx/algorithm.hpp[777].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::remove_if*

template<typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
FwdIter `hpx::remove`(*FwdIter* first, *FwdIter* last, *T* const &value)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*.

The assignments in the parallel *remove* algorithm execute in sequential order in the calling thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the operator==().

Template Parameters

---

[777] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`T`** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`value`** – Specifies the value of elements to remove.

Returns

The *remove* algorithm returns a *FwdIter*. The *remove* algorithm returns the iterator to the new end of the range.

template<typename **ExPolicy**, typename **FwdIter**, typename **T** = typename *std*::iterator_traits<*FwdIter*>::value_type>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **`hpx::remove`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *T* const &value)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*. Executed according to the policy.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the operator==().

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`T`** – The type of the value to remove (deduced). This value type must meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`value`** – Specifies the value of elements to remove.

Returns

The *remove* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *remove* algorithm returns the iterator to the new end of the range.

hpx::remove_if

Defined in header hpx/algorithm.hpp[778].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::remove*

template<typename **FwdIter**, typename **Pred**>
FwdIter `hpx::`**`remove_if`**(*FwdIter* first, *FwdIter* last, *Pred* &&pred)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true.

The assignments in the parallel *remove_if* algorithm execute in sequential order in the calling thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_if* requires *Pred* to meet the requirements of *CopyConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

---

[778] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_if* algorithm returns a *FwdIter*. The *remove_if* algorithm returns the iterator to the new end of the range.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::remove_if`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate *pred* returns true. Executed according to the policy.

The assignments in the parallel *remove_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *remove_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_if* requires *Pred* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *remove_if* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *remove_if* algorithm returns the iterator to the new end of the range.

hpx/parallel/algorithms/transform_reduce_binary.hpp

Defined in header hpx/parallel/algorithms/transform_reduce_binary.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::partial_sort

Defined in header hpx/algorithm.hpp[779].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
RandIter **hpx::partial_sort**(*RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

Note

Complexity: Approximately (last - first) * log(middle - first) comparisons.

Template Parameters

- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to detail::less.

Returns

The *partial_sort* algorithm returns a *RandIter* that refers to *last*.

---

[779] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

template<typename **ExPolicy**, typename **RandIter**, typename **Comp** = *hpx*::*parallel*::detail::less>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *RandIter*> **hpx::partial_sort**(*ExPolicy* &&policy, *RandIter* first, *RandIter* middle, *RandIter* last, *Comp* &&comp = *Comp*())

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

> **Note**
>
> Complexity: Approximately (last - first) * log(middle - first) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to detail::less.

Returns

The *partial_sort* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandIter* otherwise. The iterator returned refers to *last*.

hpx::experimental::reduction

Defined in header hpx/algorithm.hpp[780].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **Op**>

---

[780] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::decay_t<*Op*>> `hpx::experimental::`**`reduction`**`(`*T* &var, *T* const &identity, *Op* &&combiner)

The function template returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, a combiner function object, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses reduction objects by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the reduction object's combiner operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*. The expression

```
var = combiner(var, var)
```

shall be well-formed.

Note

In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation. For example if the combiner is plus<T>, incrementing the view would be consistent with the combiner but doubling it or assigning to it would not.

Template Parameters

- **`T`** – The value type to be used by the induction object.
- **`Op`** – The type of the binary function (object) used to perform the reduction operation.

Parameters

- **`var`** – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **`identity`** – [in] The identity value to use for the reduction operation. This argument is optional and defaults to a copy of *var*.
- **`combiner`** – [in] The binary function (object) used to perform a pairwise reduction on the elements.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**, typename **Op**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::decay_t<*Op*>> `hpx::experimental::`**`reduction`**(*T* &var, *Op* &&combiner)

hpx::experimental::reduction_max

Defined in header hpx/algorithm.hpp[781].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *hpx*::*parallel*::detail::max_of<*T*>> `hpx::experimental::`**`reduction_max`**(*T* &va

The function template *reduction_max* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::max_of{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_max* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::max_of{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

Note

In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **`T`** – The value type to be used by the induction object.
- **`Op`** – The type of the binary function (object) used to perform the reduction operation.

Parameters

`var` – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing. The optional *identity* value is used for the reduction operation and defaults to a copy of *var*.

---

[781] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *hpx*::*parallel*::detail::max_of<*T*>> `hpx::experimental::`**`reduction_max`**`(`*T* &va *T* con &id tity)

hpx::reverse

Defined in header hpx/algorithm.hpp[782].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::reverse_copy*

template<typename **BidirIter**>
void `hpx::`**`reverse`**`(`*BidirIter* first, *BidirIter* last)

Reverses the order of the elements in the range [first, last). Behaves as if applying *std::iter_swap* to every pair of iterators first+i, (*last-i*) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel *reverse* algorithm execute in sequential order in the calling thread.

Note

Complexity: Linear in the distance between *first* and *last*.

Template Parameters

`BidirIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reverse* algorithm returns *void*.

template<typename **ExPolicy**, typename **BidirIter**>

---

[782] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, void> `hpx::reverse`(*ExPolicy* &&policy, *BidirIter* first, *BidirIter* last)

Reverses the order of the elements in the range [first, last). Behaves as if applying *std::iter_swap* to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2. Executed according to the policy.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Linear in the distance between *first* and *last*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`BidirIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *reverse* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::reverse_copy

Defined in header hpx/algorithm.hpp[783].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::reverse*

template<typename **`BidirIter`**, typename **`OutIter`**>
OutIter `hpx::reverse_copy`(*BidirIter* first, *BidirIter* last, *OutIter* dest)

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined.

---

[783] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *reverse_copy* algorithm execute in sequential order in the calling thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`BidirIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the begin of the destination range.

Returns

The *reverse_copy* algorithm returns an *OutIter*. The *reverse_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **ExPolicy**, typename **BidirIter**, typename **FwdIter**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **`hpx::reverse_copy`**(*ExPolicy* &&policy, *BidirIter* first, *BidirIter* last, *FwdIter* dest)

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined. Executed according to the policy.

The assignments in the parallel *reverse_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *reverse_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **`BidirIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the begin of the destination range.

Returns

The *reverse_copy* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *reverse_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::move

Defined in header hpx/algorithm.hpp[784].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::move`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Moves the elements in the range [first, last), to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move. Executed according to the policy.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The move assignments in the parallel *move* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* move assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the move assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

---

[784] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *move* algorithm returns a *hpx::future<FwdIter2>>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

template<typename **FwdIter1**, typename **FwdIter2**>
FwdIter2 `hpx::move`(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Moves the elements in the range [first, last), to another range beginning at *dest*. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

Note

Complexity: Performs exactly *last* - *first* move assignments.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *move* algorithm returns a *FwdIter2*. The *move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

hpx::ends_with

Defined in header hpx/algorithm.hpp[785].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter1**, typename **InIter2**, typename **Pred** = *hpx*::*parallel*::detail::equal_to>
bool `hpx::ends_with`(*InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2)

The assignments in the parallel *ends_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- `InIter1` – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `InIter2` – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a input iterator.
- `Pred` – The binary predicate that compares the elements. This defaults to *hpx::parallel::detail::equal_to*.

Parameters

- `first1` – Refers to the beginning of the source range.
- `last1` – Refers to the end of the source range.
- `first2` – Refers to the beginning of the destination range.
- `last2` – Refers to the end of the destination range.
- `pred` – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *ends_with* algorithm returns *bool*. The *ends_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *ranges*::equal_to>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, bool>::type `hpx::ends_with`(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2). Executed according to the policy.

---

[785] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *ends_with* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *ends_with* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The binary predicate that compares the elements. This defaults to *ranges::equal_to*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the source range.
- **`last1`** – Refers to the end of the source range.
- **`first2`** – Refers to the beginning of the destination range.
- **`last2`** – Refers to the end of the destination range.
- **`pred`** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *ends_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *ends_with* algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

hpx::search

Defined in header hpx/algorithm.hpp[786].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::search_n*

template<typename **`FwdIter`**, typename **`FwdIter2`**, typename **`Pred`** = *parallel*::detail::equal_to>

---

[786] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

FwdIter `hpx::search`(*FwdIter* first, *FwdIter* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search* algorithm execute in sequential order in the calling thread.

Note

Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **`FwdIter`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to<>*

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`s_first`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`s_last`** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **`op`** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *search* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`FwdIter2`**, typename **`Pred`** = *parallel*::detail::equal_to>

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **hpx::search**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to<>*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *search* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *search* algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), *last* is returned. Additionally if the size of the subsequence is empty *first* is returned. If no subsequence is found, *last* is returned.

template<typename **`FwdIter`**, typename **`Searcher`**>
FwdIter `hpx::`**`search`**`(`*FwdIter* first, *FwdIter* last, *Searcher* &&searcher`)`

Searches the range [first, last) using a searcher object.

Template Parameters

- **`FwdIter`** – The type of the source iterators (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Searcher`** – A callable searcher object meeting the C++ Searcher requirements (e.g. std::boyer_moore_searcher).

Parameters

- **`first`** – Refers to the beginning of the sequence to search.
- **`last`** – Refers to the end of the sequence to search.
- **`searcher`** – A callable object performing the search.

Returns

An iterator to the beginning of the found subsequence, or *last* if no subsequence is found.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Searcher`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::`**`search`**`(`*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Searcher* &&searcher`)`

Searches the range [first, last) using a searcher object. Executed according to the policy.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced).
- **`FwdIter`** – The type of the source iterators (deduced).
- **`Searcher`** – A callable searcher object meeting the C++ Searcher requirements.

Parameters

- **`policy`** – The execution policy to use.
- **`first`** – Refers to the beginning of the sequence to search.
- **`last`** – Refers to the end of the sequence to search.
- **`searcher`** – A callable object performing the search.

Returns

The algorithm returns a *hpx::future<FwdIter>* if the execution policy is a task policy, or *FwdIter* otherwise.

hpx::search_n

Defined in header hpx/algorithm.hpp[787].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::search*

template<typename **FwdIter**, typename **FwdIter2**, typename **Pred** = *parallel*::detail::equal_to>
FwdIter `hpx::search_n`(*FwdIter* first, *std*::size_t count, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel *search_n* algorithm execute in sequential order in the calling thread.

Note

Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = count.

Template Parameters

- **`FwdIter`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search_n* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to<>*

Parameters

- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`count`** – Refers to the range of elements of the first range the algorithm will be applied to.
- **`s_first`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`s_last`** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **`op`** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

---

[787] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Returns

The *search_n* algorithm returns *FwdIter*. The *search_n* algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`FwdIter2`**, typename **`Pred`** = *parallel*::detail::equal_to>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **`hpx::search_n`**(*ExPolicy* &&policy, *FwdIter* first, *std*::size_t count, *FwdIter2* s_first, *FwdIter2* s_last, *Pred* &&op = *Pred*())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel *search_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *search_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: at most (S*N) comparisons where *S* = distance(s_first, s_last) and *N* = count.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *search_n* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to *std::equal_to*<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`count`** – Refers to the range of elements of the first range the algorithm will be applied to.
- **`s_first`** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **`s_last`** – Refers to the end of the sequence of elements of the algorithm will be searching for.

- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *search_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *task_execution_policy* and returns *FwdIter* otherwise. The *search_n* algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

hpx::exclusive_scan

Defined in header hpx/algorithm.hpp[788].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **OutIter**, typename **T**>
OutIter hpx::**exclusive_scan**(*InIter* first, *InIter* last, *OutIter* dest, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, …, *(first + (i - result) - 1))

The reduce operations in the parallel *exclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *std::plus<T>*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

---

[788] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`init`** – The initial value for the generalized sum.

Returns

The *exclusive_scan* algorithm returns *OutIter*. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`T`**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx`::**`exclusive_scan`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* init)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, …, *(first + (i - result) - 1))

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum.

Note

Complexity: O(*last* - *first*) applications of the predicate *std::plus<T>*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.

Returns

The *exclusive_scan* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **InIter**, typename **OutIter**, typename **T**, typename **Op**>
OutIter hpx::**exclusive_scan**(*InIter* first, *InIter* last, *OutIter* dest, *T* init, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, …, *(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive_scan* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

Note

Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).
- **`Op`** – The type of the binary function object used for the reduction operation.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`init`** – The initial value for the generalized sum.
- **`op`** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *exclusive_scan* algorithm returns *OutIter*. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Op`**, typename **`T`**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx`::**`exclusive_scan`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *T* init, *Op* &&op)

Assigns through each iterator *i* in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, …, *(first + (i - result) - 1)).

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *exclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between *exclusive_scan* and *inclusive_scan* is that *inclusive_scan* includes the ith input element in the ith sum. If *op* is not mathematically associative, the behavior of *inclusive_scan* may be non-deterministic.

> **Note**
>
> Complexity: O(*last* - *first*) applications of the predicate *op*.

Note

GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Op`** – The type of the binary function object used for the reduction operation.
- **`T`** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`init`** – The initial value for the generalized sum.
- **`op`** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Ret* must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns

The *exclusive_scan* algorithm returns a *hpx::future<OutIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *OutIter* otherwise. The *exclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::partition

Defined in header hpx/algorithm.hpp[789].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::stable_partition*
- *hpx::partition_copy*

template<typename **FwdIter**, typename **Pred**, typename **Proj** = *hpx*::*identity*>
FwdIter `hpx::partition`(*FwdIter* first, *FwdIter* last, *Pred* &&pred, *Proj* &&proj = *Proj*())

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: At most 2 * (last - first) swaps. Exactly *last - first* applications of the predicate and projection.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

---

[789] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Returns

The *partition* algorithm returns returns *FwdIter*. The *partition* algorithm returns the iterator to the first element of the second group.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred**, typename **Proj** = *hpx*::*identity*>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **hpx::partition**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred, *Proj* &&proj = *Proj*())

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2 * (last - first) swaps. Exactly *last* - *first* applications of the predicate and projection.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

Returns

The *partition* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *parallel_task_policy* and returns *FwdIter* otherwise. The *partition* algorithm returns the iterator to the first element of the second group.

hpx::stable_partition

Defined in header hpx/algorithm.hpp[790].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::partition*
- *hpx::partition_copy*

template<typename **BidirIter**, typename **F**, typename **Proj** = *hpx*::*identity*>
BidirIter hpx::**stable_partition**(*BidirIter* first, *BidirIter* last, *F* &&f, *Proj* &&proj = *Proj*())

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) INVOKE(f, INVOKE (proj, *j)) != false, and for every iterator k in the range [i, last), INVOKE(f, INVOKE (proj, *k)) == false

The invocations of *f* in the parallel *stable_partition* algorithm invoked without an execution policy object executes in sequential order in the calling thread.

Note

Complexity: At most (last - first) * log(last - first) swaps, but only linear number of swaps if there is enough extra memory. Exactly *last* - *first* applications of the predicate and projection.

Template Parameters

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

---

[790] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

```
bool fun(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

Returns

The *stable_partition* algorithm returns an iterator i such that for every iterator j in the range [first, i), f(*j) != false INVOKE(f, INVOKE(proj, *j)) != false, and for every iterator k in the range [i, last), f(*k) == false INVOKE(f, INVOKE (proj, *k)) == false. The relative order of the elements in both groups is preserved.

template<typename **ExPolicy**, typename **BidirIter**, typename **F**, typename **Proj** = *hpx*::*identity*>
parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *BidirIter*> `hpx::`**`stable_partition`**(*ExPolicy* &&policy, *BidirIter* first, *BidirIter* last, *F* &&f, *Proj* &&proj = *Proj*())

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) INVOKE(f, INVOKE (proj, *j)) != false, and for every iterator k in the range [i, last), INVOKE(f, INVOKE (proj, *k)) == false

The invocations of *f* in the parallel *stable_partition* algorithm invoked with an execution policy object of type *sequenced_policy* executes in sequential order in the calling thread.

The invocations of *f* in the parallel *stable_partition* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most (last - first) * log(last - first) swaps, but only linear number of swaps if there is enough extra memory. Exactly *last* - *first* applications of the predicate and projection.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of *f*.
- **`BidirIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *transform* requires *F* to meet the requirements of *CopyConstructible*.
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool fun(const Type &a);
  ```

  The signature does not need to have const&. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

Returns

The *stable_partition* algorithm returns an iterator i such that for every iterator j in the range [first, i), f(*j) != false INVOKE(f, INVOKE(proj, *j)) != false, and for every iterator k in the range [i, last), f(*k) == false INVOKE(f, INVOKE (proj, *k)) == false. The relative order of the elements in both groups is preserved. If the execution policy is of type *parallel_task_policy* the algorithm returns a *future*<> referring to this iterator.

hpx::partition_copy

Defined in header hpx/algorithm.hpp[791].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::partition*
- *hpx::stable_partition*

template<typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred**, typename **Proj** = *hpx*::*identity*>
std::pair<*FwdIter2*, *FwdIter3*> **hpx::partition_copy**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest_true, *FwdIter3* dest_false, *Pred* &&pred, *Proj* &&proj = *Proj*())

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred* are copied to the range beginning at *dest_true*. The rest of the elements are copied to the range beginning at *dest_false*. The order of the elements is preserved.

The assignments in the parallel *partition_copy* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

---

[791] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter2`** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest_true`** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **`dest_false`** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.
- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

Returns

The *partition_copy* algorithm returns *std::pair<OutIter1, OutIter2>*. The *partition_copy* algorithm returns the pair of the destination iterator to the end of the *dest_true* range, and the destination iterator to the end of the *dest_false* range.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`FwdIter3`**, typename **`Pred`**, typename **`Proj`** = *hpx*::*identity*>

parallel::*util*::detail::algorithm_result_t<*ExPolicy*, *std*::pair<*FwdIter2*, *FwdIter3*>> `hpx::partition_copy`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest_true, *FwdIter3* dest_false, *Pred* &&pred, *Proj* &&proj = *Proj*())

Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate *pred*. The elements, that satisfy the predicate *pred*, are copied to the range beginning at *dest_true*. The rest of the elements are copied to the range beginning at *dest_false*. The order of the elements is preserved.

The assignments in the parallel *partition_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *partition_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *pred*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range for the elements that satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range for the elements that don’t satisfy the predicate *pred* (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition_copy* requires *Pred* to meet the requirements of *CopyConstructible*.
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest_true`** – Refers to the beginning of the destination range for the elements that satisfy the predicate *pred*
- **`dest_false`** – Refers to the beginning of the destination range for the elements that don't satisfy the predicate *pred*.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.
- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *is* invoked.

Returns

The *partition_copy* algorithm returns a hpx::future<*std::pair<OutIter1, OutIter2>*> if the execution policy is of type *parallel_task_policy* and returns *std::pair<OutIter1, OutIter2>* otherwise. The *partition_copy* algorithm returns the pair of the destination iterator to the end of the *dest_true* range, and the destination iterator to the end of the *dest_false* range.

hpx::unique

Defined in header hpx/algorithm.hpp[792].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::unique_copy*

template<typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to, typename **Proj** = *hpx*::*identity*>
FwdIter **hpx::unique**(*FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

Template Parameters

---

[792] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*
- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique* algorithm returns *FwdIter*. The *unique* algorithm returns the iterator to the new end of the range.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Pred`** = *hpx*::*parallel*::detail::equal_to, typename **`Proj`** = *hpx*::*identity*>
parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*>::type **`hpx::unique`**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Eliminates all but the first element from every consecutive group of equivalent elements from the range [first, last) and returns a past-the-end iterator for the new logical end of the range. Executed according to the policy.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter* can be dereferenced and then implicitly converted to both *Type1* and *Type2*
- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *unique* algorithm returns the iterator to the new end of the range.

hpx::unique_copy

Defined in header hpx/algorithm.hpp[793].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::unique*

template<typename **`InIter`**, typename **`OutIter`**, typename **`Pred`** = *hpx*::*parallel*::detail::equal_to, typename **`Proj`** = *hpx*::*identity*>
OutIter `hpx::`**`unique_copy`**(*InIter* first, *InIter* last, *OutIter* dest, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

---

[793] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`OutIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique_copy* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.
- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique_copy* algorithm returns a returns *OutIter*. The *unique_copy* algorithm returns the destination iterator to the end of the *dest* range.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`FwdIter2`**, typename **`Pred`** = *hpx*::*parallel*::detail::equal_to, typename **`Proj`** = *hpx*::*identity*>
parallel::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter2*>::type `hpx::`**`unique_copy`**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred = *Pred*(), *Proj* &&proj = *Proj*())

Copies the elements from the range [first, last), to another range beginning at *dest* in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied. Executed according to the policy.

The assignments in the parallel *unique_copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *unique_copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* - 1 applications of the predicate *pred* and no more than twice as many applications of the projection *proj*

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *unique_copy* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **`Proj`** – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`pred`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.
- **`proj`** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *pred* is invoked.

Returns

The *unique_copy* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *unique_copy* algorithm returns the pair of the source iterator to *last*, and the destination iterator to the end of the *dest* range.

hpx::experimental::reduction_multiplies

Defined in header hpx/algorithm.hpp[794].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::multiplies<*T*>> `hpx::experimental::`**`reduction_multiplies`**(*T* &var)

The function template *reduction_multiplies* returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, it uses std::multiplies{} as its combiner function, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses the *reduction_multiplies* object by allocating an unspecified number of instances, called views, of the reduction's value type. Each view is initialized with the reduction object's identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the std::multiplies{} operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of *CopyConstructible* and *MoveAssignable*.

> **Note**
>
> In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation.

Template Parameters

- **`T`** – The value type to be used by the induction object.
- **`Op`** – The type of the binary function (object) used to perform the reduction operation.

Parameters

`var` – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing. The optional *identity* value is used for the reduction operation and defaults to `T(1)`.

Returns

This returns a reduction object of unspecified type having a value type of *T*. When the return value is used by an algorithm, the reference to *var* is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

template<typename **T**>
constexpr *hpx*::*parallel*::detail::reduction_helper<*T*, *std*::multiplies<*T*>> `hpx::experimental::`**`reduction_multiplies`**(*T* &var, *T* const &identity)

---

[794] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::stable_sort

Defined in header hpx/algorithm.hpp[795].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandomIt**, typename **Comp** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::*identity*>
void *hpx*::**stable_sort**(*RandomIt* first, *RandomIt* last, *Comp* &&comp = *Comp*(), *Proj* &&proj = *Proj*())

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The assignments in the parallel *stable_sort* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *stable_sort* algorithm returns *void*.

template<typename **ExPolicy**, typename **RandomIt**, typename **Comp** = *hpx*::*parallel*::detail::less, typename **Proj** = *hpx*::*identity*>

---

[795] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> `hpx::stable_sort`(*ExPolicy* &&policy, *RandomIt* first, *RandomIt* last, *Comp* &&comp = *Comp*(), *Proj* &&proj = *Proj*())

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator *comp* and a projection *proj* if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate *comp* is invoked.

Returns

The *stable_sort* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *void* otherwise.

hpx::adjacent_find

Defined in header hpx/algorithm.hpp[796].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to>
InIter **hpx::adjacent_find**(*InIter* first, *InIter* last, *Pred* &&pred = *Pred*())

Searches the range [first, last) for two consecutive identical elements.

> **Note**
>
> Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

Template Parameters

- **InIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1* .

Returns

The *adjacent_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **Pred** = *hpx*::*parallel*::detail::equal_to>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **hpx::adjacent_find**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *Pred* &&pred = *Pred*())

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate pred

The comparison operations in the parallel *adjacent_find* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

---

[796] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The comparison operations in the parallel *adjacent_find* invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of *adjacent_find* is available if the user decides to provide their algorithm their own binary predicate *pred*.

Note

Complexity: Exactly the smaller of (*result* - *first*) + 1 and (*last* - *first*) - 1 application of the predicate where *result* is the value returned

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *adjacent_find* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **`pred`** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1* .

Returns

The *adjacent_find* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *adjacent_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

hpx::includes

Defined in header hpx/algorithm.hpp[797].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool>::type **hpx::includes**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*. Executed according to the policy.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparison operations in the parallel *includes* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

At most 2*(N1+N2-1) comparisons, where N1 = std::distance(first1, last1) and N2 = std::distance(first2, last2).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

---

[797] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *includes* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *includes* algorithm returns true every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred** = *hpx*::*parallel*::detail::less>
bool `hpx::`**`includes`**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *Pred* &&op = *Pred*())

Returns true if every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty. The version expects both ranges to be sorted with the user supplied binary predicate *f*.

> **Note**
>
> At most 2*(N1+N2-1) comparisons, where N1 = std::distance(first1, last1) and N2 = std::distance(first2, last2).

Template Parameters

- **`FwdIter1`** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Pred`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`op`** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively

Returns

The *includes* algorithm returns a *bool*. The *includes* algorithm returns true every element from the sorted range [*first2*, *last2*) is found within the sorted range [*first1*, *last1*). Also returns true if [*first2*, *last2*) is empty.

hpx::for_each

Defined in header hpx/algorithm.hpp[798].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::for_each_n*

template<typename **InIter**, typename **F**>
F `hpx::`**`for_each`**(*InIter* first, *InIter* last, *F* &&f)

Applies *f* to the result of dereferencing every iterator in the range [first, last).

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

> **Note**
>
> Complexity: Applies *f* exactly *last* - *first* times.

Template Parameters

- **`InIter`** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **`F`** – The type of the function/function object to use (deduced). F must meet requirements of *MoveConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

---

[798] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The signature does not need to have const&. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

Returns

f.

template<typename **ExPolicy**, typename **FwdIter**, typename **F**>
util::detail::algorithm_result_t<*ExPolicy*, void> `hpx::for_each`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Applies *f* to the result of dereferencing every iterator in the range [first, last). Executed according to the policy.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Applies *f* exactly *last* - *first* times.

Template Parameters

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `FwdIter` – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of a forward iterator.
- `F` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for_each* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `f` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *for_each* algorithm returns a *hpx::future<void>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns void otherwise.

hpx::for_each_n

Defined in header hpx/algorithm.hpp[799].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::for_each*

template<typename **InIter**, typename **Size**, typename **F**>
InIter `hpx::`**`for_each_n`**(*InIter* first, *Size* count, *F* &&f)

Applies *f* to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

> **Note**
>
> Complexity: Applies *f* exactly *count* times.

Template Parameters

- **`InIter`** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`F`** – The type of the function/function object to use (deduced). F must meet requirements of *MoveConstructible*.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to Type.

---

[799] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Returns

first + *count* for non-negative values of *count* and *first* for negative values.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Size`**, typename **`F`**>
util::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::`**`for_each_n`**(*ExPolicy* &&policy, *FwdIter* first, *Size* count, *F* &&f)

Applies *f* to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1. Executed according to the policy.

If *f* returns a result, the result is ignored.

If the type of *first* satisfies the requirements of a mutable iterator, *f* may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for_each_n* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Applies *f* exactly *count* times.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for_each_n* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`f`** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to Type.

Returns

The *for_each_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. It returns *first* + *count* for non-negative values of *count* and *first* for negative values.

hpx::min_element

Defined in header hpx/algorithm.hpp[800].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::max_element*
- *hpx::minmax_element*

template<typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>
FwdIter **hpx::min_element**(*FwdIter* first, *FwdIter* last, *F* &&f)

Finds the smallest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min_element* algorithm execute in sequential order in the calling thread.

Note

Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced).

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *min_element* algorithm returns *FwdIter*. The *min_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

---

[800] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

template<typename **ExPolicy**, typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> **hpx::min_element**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Finds the smallest element in the range [first, last) using the given comparison function *f*. Executed according to the policy.

The comparisons in the parallel *min_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *min_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *min_element* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *min_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *min_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

hpx::max_element

Defined in header hpx/algorithm.hpp[801].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::min_element*
- *hpx::minmax_element*

template<typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>
FwdIter **hpx::max_element**(*FwdIter* first, *FwdIter* last, *F* &&f)

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *min_element* algorithm execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if left argument is less than the right element. This argument is optional and defaults to std::less. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *max_element* algorithm returns *FwdIter*. The *max_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

template<typename **ExPolicy**, typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result<*ExPolicy*, *FwdIter*>::type **hpx::max_element**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

---

[801] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Removes all elements satisfying specific criteria from the range Finds the largest element in the range [first, last) using the given comparison function *f*. Executed according to the policy.

The comparisons in the parallel *max_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *max_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Exactly *max*(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *max_element* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – The binary predicate which returns true if left argument is less than the right element. This argument is optional and defaults to std::less. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *max_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *max_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

hpx::minmax_element

Defined in header hpx/algorithm.hpp[802].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::min_element*
- *hpx::max_element*

template<typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>
minmax_element_result<*FwdIter*> **hpx::minmax_element**(*FwdIter* first, *FwdIter* last, *F* &&f)

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *minmax_element* algorithm execute in sequential order in the calling thread.

Note

Complexity: At most *max*(floor(3/2*(N-1)), 0) applications of the predicate, where N = std::distance(first, last).

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *minmax_element* algorithm returns a *minmax_element_result<FwdIter>* The *minmax_element* algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns *minmax_element_result<FwdIter>{first*,first} if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

template<typename **ExPolicy**, typename **FwdIter**, typename **F** = *hpx*::*parallel*::detail::less>

---

[802] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, minmax_element_result<*FwdIter*>> `hpx::minmax_element`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last, *F* &&f)

Finds the largest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *minmax_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The comparisons in the parallel *minmax_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: At most *max*(floor(3/2*(N-1)), 0) applications of the predicate, where N = std::distance(first, last).

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`F`** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *minmax_element* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`f`** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.

Returns

The *minmax_element* algorithm returns a hpx::future<*minmax_element_result<FwdIter>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *minmax_element_result<FwdIter>* otherwise. The *minmax_element* algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns *std::make_pair(first,first)* if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

hpx::uninitialized_move

Defined in header hpx/algorithm.hpp[803].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_move_n*

template<typename **InIter**, typename **FwdIter**>
FwdIter hpx::**uninitialized_move**(*InIter* first, *InIter* last, *FwdIter* dest)

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move* algorithm returns *FwdIter*. The *uninitialized_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> hpx::**uninitialized_move**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

---

[803] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at *dest*. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state. Executed according to the policy.

The assignments in the parallel *uninitialized_move* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_move* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *last - first* assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move* algorithm returns a *hpx::future<FwdIter2>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *uninitialized_move* algorithm returns the output iterator to the element in the destination range, one past the last element moved.

hpx::uninitialized_move_n

Defined in header hpx/algorithm.hpp[804].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_move*

template<typename **`InIter`**, typename **`Size`**, typename **`FwdIter`**>

---

[804] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

std::pair<*InIter*, *FwdIter*> `hpx::uninitialized_move_n`(*InIter* first, *Size* count, *FwdIter* dest)

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state.

> **Note**
>
> Complexity: Performs exactly *count* movements, if count > 0, no move operations otherwise.

Template Parameters

- **`InIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`FwdIter`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move_n* algorithm returns a returns *std::pair<InIter,FwdIter>*. The *uninitialized_move_n* algorithm returns A pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`Size`**, typename **`FwdIter2`**>
parallel::*util*::detail::algorithm_result<*ExPolicy*, *std*::pair<*FwdIter1*, *FwdIter2*>>::type `hpx::uninitialized_move_n`(*ExPolicy* &&policy, *FwdIter1* first, *Size* count, *FwdIter2* dest)

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state. Executed according to the policy.

The assignments in the parallel *uninitialized_move_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_move_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *count* movements, if count > 0, no move operations otherwise.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *uninitialized_move_n* algorithm returns a hpx::future<*std::pair<FwdIter1,FwdIter2>*> if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *std::pair<FwdIter1,FwdIter2>* otherwise. The *uninitialized_move_n* algorithm returns A pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

hpx::set_union

Defined in header hpx/algorithm.hpp[805].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter3*> **hpx::set_union**(*ExPolicy* &&policy, *FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

---

[805] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), then all *m* elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (for *sequenced_task_policy*).

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **`FwdIter1`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter2`** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **`FwdIter3`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **`Op`** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **`last1`** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **`first2`** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **`last2`** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.
- **`op`** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_union* algorithm returns a *hpx::future<FwdIter3>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter3* otherwise. The *set_union* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**, typename **FwdIter3**, typename **Pred** = *hpx*::*parallel*::detail::less>
FwdIter3 **hpx::set_union**(*FwdIter1* first1, *FwdIter1* last1, *FwdIter2* first2, *FwdIter2* last2, *FwdIter3* dest, *Pred* &&op = *Pred*())

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

If some element is found *m* times in [first1, last1) and *n* times in [first2, last2), then all *m* elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

The resulting range cannot overlap with either of the input ranges.

Note

Complexity: At most 2*(N1 + N2 - 1) comparisons, where *N1* is the length of the first sequence and *N2* is the length of the second sequence.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *set_union* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::less<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*

Returns

The *set_union* algorithm returns a *FwdIter3*. The *set_union* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

hpx::uninitialized_value_construct

Defined in header hpx/algorithm.hpp[806].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_value_construct_n*

template<typename **FwdIter**>
void *hpx*::**uninitialized_value_construct**(*FwdIter* first, *FwdIter* last)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_value_construct* algorithm returns nothing

template<typename **ExPolicy**, typename **FwdIter**>

---

[806] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> `hpx::uninitialized_value_construct`(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized_value_construct* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_value_construct* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_value_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns nothing otherwise.

hpx::uninitialized_value_construct_n

Defined in header hpx/algorithm.hpp[807].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_value_construct*

template<typename **`FwdIter`**, typename **`Size`**>

---

[807] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

FwdIter `hpx::`**`uninitialized_value_construct_n`**(*FwdIter* first, *Size* count)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_value_construct_n* algorithm returns a returns *FwdIter*. The *uninitialized_value_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename **`ExPolicy`**, typename **`FwdIter`**, typename **`Size`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::`**`uninitialized_value_construct_n`**(*ExPolicy* &&policy, *FwdIter* first, *Size* count)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized_value_construct_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_value_construct_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_value_construct_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_value_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

hpx::starts_with

Defined in header hpx/algorithm.hpp[808].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`InIter1`**, typename **`InIter2`**, typename **`Pred`** = *hpx*::*parallel*::detail::equal_to>
bool `hpx::starts_with`(*InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2)

The assignments in the parallel *starts_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- **`InIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`InIter2`** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`Pred`** – The binary predicate that compares the elements. This defaults to *hpx::parallel::detail::equal_to*.

Parameters

- **`first1`** – Refers to the beginning of the source range.

---

[808] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`last1`** – Sentinel value referring to the end of the source range.
- **`first2`** – Refers to the beginning of the destination range.
- **`last2`** – Sentinel value referring to the end of the destination range.
- **`pred`** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *starts_with* algorithm returns *bool*. The *starts_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

template<typename **ExPolicy**, typename **InIter1**, typename **InIter2**, typename **Pred** = *ranges*::equal_to>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, bool> **hpx::starts_with**(*ExPolicy* &&policy, *InIter1* first1, *InIter1* last1, *InIter2* first2, *InIter2* last2, *Pred* &&pred = *Pred*())

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2). Executed according to the policy.

The assignments in the parallel *starts_with* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: Linear: at most min(N1, N2) applications of the predicate.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`InIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`InIter2`** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **`Pred`** – The binary predicate that compares the elements. This defaults to *ranges::equal_to*.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first1`** – Refers to the beginning of the source range.
- **`last1`** – Sentinel value referring to the end of the source range.
- **`first2`** – Refers to the beginning of the destination range.
- **`last2`** – Sentinel value referring to the end of the destination range.
- **`pred`** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges.

Returns

The *starts_with* algorithm returns a *hpx::future<bool>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *bool* otherwise. The *starts_with* algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

hpx::uninitialized_default_construct

Defined in header hpx/algorithm.hpp[809].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_default_construct_n*

template<typename **FwdIter**>
void *hpx*::**uninitialized_default_construct**(*FwdIter* first, *FwdIter* last)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel *uninitialized_default_construct* algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

> **Note**
>
> Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_default_construct* algorithm returns nothing

template<typename **ExPolicy**, typename **FwdIter**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*> *hpx*::**uninitialized_default_construct**(*ExPolicy* &&policy, *FwdIter* first, *FwdIter* last)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

---

[809] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

The assignments in the parallel *uninitialized_default_construct* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_default_construct* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns

The *uninitialized_default_construct* algorithm returns a *hpx::future<void>*, if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns nothing otherwise.

hpx::uninitialized_default_construct_n

Defined in header hpx/algorithm.hpp[810].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::uninitialized_default_construct*

template<typename **FwdIter**, typename **Size**>
FwdIter `hpx::uninitialized_default_construct_n`(*FwdIter* first, *Size* count)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

Note

Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

---

[810] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_default_construct_n* algorithm returns a returns *FwdIter*. The *uninitialized_default_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename **ExPolicy**, typename **FwdIter**, typename **Size**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter*> `hpx::`**`uninitialized_default_construct_n`**(*ExPolicy* &&policy, *FwdIter* first, *Size* count)

Constructs objects of type `iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel *uninitialized_default_construct_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *uninitialized_default_construct_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements starting at *first* the algorithm will be applied to.

Returns

The *uninitialized_default_construct_n* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *uninitialized_default_construct_n* algorithm returns the iterator to the element in the source range, one past the last element constructed.

hpx::copy

Defined in header hpx/algorithm.hpp[811].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::copy_n*
- *hpx::copy_if*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx::copy`(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Executed according to the policy.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

---

[811] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *copy* algorithm returns a *hpx::future<FwdIter2> >* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2>* otherwise. The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

template<typename **`FwdIter1`**, typename **`FwdIter2`**>
FwdIter2 `hpx`::**`copy`**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*.

Note

Complexity: Performs exactly *last* - *first* assignments.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *copy* algorithm returns a *FwdIter2* . The *copy* algorithm returns the pair of the input iterator *last* and the output iterator to the element in the destination range, one past the last element copied.

hpx::copy_n

Defined in header hpx/algorithm.hpp[812].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::copy*
- *hpx::copy_if*

template<typename **`ExPolicy`**, typename **`FwdIter1`**, typename **`Size`**, typename **`FwdIter2`**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> `hpx`::**`copy_n`**(*ExPolicy* &&policy, *FwdIter1* first, *Size* count, *FwdIter2* dest)

---

[812] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. Executed according to the policy.

The assignments in the parallel *copy_n* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy_n* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.
- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *copy_n* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *copy_n* algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

template<typename **`FwdIter1`**, typename **`Size`**, typename **`FwdIter2`**>
FwdIter2 `hpx::`**`copy_n`**(*FwdIter1* first, *Size* count, *FwdIter2* dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest.

> **Note**
>
> Complexity: Performs exactly *count* assignments, if count > 0, no assignments otherwise.

Template Parameters

- **`FwdIter1`** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **`Size`** – The type of the argument specifying the number of elements to apply *f* to.
- **`FwdIter2`** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`count`** – Refers to the number of elements starting at *first* the algorithm will be applied to.
- **`dest`** – Refers to the beginning of the destination range.

Returns

The *copy_n* algorithm returns a *FwdIter2* . The *copy_n* algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

hpx::copy_if

Defined in header hpx/algorithm.hpp[813].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::copy*
- *hpx::copy_n*

template<typename **ExPolicy**, typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>
hpx::*parallel*::*util*::detail::algorithm_result_t<*ExPolicy*, *FwdIter2*> **hpx::copy_if**(*ExPolicy* &&policy, *FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved. Executed according to the policy.

The assignments in the parallel *copy_if* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *copy_if* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *f*.

Template Parameters

---

[813] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.

Returns

The *copy_if* algorithm returns a *hpx::future<FwdIter2> >* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *copy_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

template<typename **FwdIter1**, typename **FwdIter2**, typename **Pred**>
FwdIter2 `hpx::`**`copy_if`**(*FwdIter1* first, *FwdIter1* last, *FwdIter2* dest, *Pred* &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at *dest*. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved.

> **Note**
>
> Complexity: Performs not more than *last* - *first* assignments, exactly *last* - *first* applications of the predicate *f*.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy_if* requires *F* to meet the requirements of *CopyConstructible*.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last).This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to Type.

Returns

The *copy_if* algorithm returns a *FwdIter2* . The *copy_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

hpx::nth_element

Defined in header hpx/algorithm.hpp[814].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **RandomIt**, typename **Pred** = *hpx*::*parallel*::detail::less>
void `hpx::nth_element`(*RandomIt* first, *RandomIt* nth, *RandomIt* last, *Pred* &&pred = *Pred*())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element. Executed according to the policy.

The comparison operations in the parallel *nth_element* algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note

Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters

- **RandomIt** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to std::less<>.

---

[814] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/algorithm.hpp

Parameters

- **`first`** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **`nth`** – Refers to the iterator defining the sort partition point
- **`last`** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **`pred`** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

  ```
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

Returns

The *nth_element* algorithms returns nothing.

template<typename **ExPolicy**, typename **RandomIt**, typename **Pred** = *hpx*::*parallel*::detail::less>
void *hpx*::**nth_element**(*ExPolicy* &&policy, *RandomIt* first, *RandomIt* nth, *RandomIt* last, *Pred* &&pred = *Pred*())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel *nth_element* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The assignments in the parallel *nth_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters

- **`ExPolicy`** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **`RandomIt`** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **`Pred`** – Comparison function object which returns true if the first argument is less than the second. This defaults to std::less<>.

Parameters

- **`policy`** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

  ```
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type *randomIt* can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

Returns

The *nth_element* algorithms returns nothing.

asio

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/asio/asio_util.hpp

Defined in header hpx/asio/asio_util.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

Functions

bool **get_endpoint**(*std*::string const &addr, *std*::uint16_t port, ::asio::ip::tcp::endpoint &ep, bool force_ipv4 = false)

std::string **get_endpoint_name**(::asio::ip::tcp::endpoint const &ep)

::asio::ip::tcp::endpoint **resolve_hostname**(*std*::string const &hostname, *std*::uint16_t port, ::asio::io_context &io_service, bool force_ipv4 = false)

detail::endpoint_iterator_type **connect_begin**(*std*::string const &address, *std*::uint16_t port, ::asio::io_context &io_service)

template<typename **Locality**>
detail::endpoint_iterator_type **connect_begin**(*Locality* const &loc, ::asio::io_context &io_service)

Returns an iterator which when dereferenced will give an endpoint suitable for a call to connect() related to this locality.

inline detail::endpoint_iterator_type **connect_end**()

void **open_socket_for_connect**(::asio::ip::tcp::socket &s, ::asio::ip::tcp::endpoint const &ep, *std*::error_code &ec)

Opens the given socket for a connection attempt to the given endpoint.

On Windows, a connection attempt to a port nobody listens on is reset by the target, but the SYN is retransmitted after the reset (twice by default), so connect() reports connection_refused only after about two seconds. The socket is configured to not retransmit the SYN, callers are expected to retry failed connection attempts themselves.

detail::endpoint_iterator_type **accept_begin**(*std*::string const &address, *std*::uint16_t port, ::asio::io_context &io_service)

template<typename **Locality**>
detail::endpoint_iterator_type **accept_begin**(*Locality* const &loc, ::asio::io_context &io_service)

Returns an iterator which when dereferenced will give an endpoint suitable for a call to accept() related to this locality.

inline detail::endpoint_iterator_type **accept_end**()

assertion

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/assertion/evaluate_assert.hpp

Defined in header hpx/assertion/evaluate_assert.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **assertion**

HPX_ASSERT

Defined in header hpx/assert.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *HPX_ASSERT_MSG*

HPX_ASSERT(expr)

This macro asserts that *expr* evaluates to true.

If `expr` evaluates to false, The source location and `msg` is being printed along with the expression and additional. Afterward, the program is being aborted. The assertion handler can be customized by calling hpx::assertion::set_assertion_handler().

Asserts are enabled if *HPX_DEBUG* is set. This is the default for `CMAKE_BUILD_TYPE=Debug`

Parameters

- **`expr`** – The expression to assert on. This can either be an expression that's convertible to bool or a callable which returns bool
- **`msg`** – The optional message that is used to give further information if the assert fails. This should be convertible to a std::string

HPX_ASSERT_MSG

Defined in header hpx/assert.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *HPX_ASSERT*

`HPX_ASSERT_MSG`(expr, msg)

↪sync(Action &&action, Target &&target, Ts&&... ts)
- template<typename F, typename ...Ts> decltype(auto) sync(F &&f, Ts&&... ts)
```

hpx::post

Defined in header hpx/future.hpp[818].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::post (distributed)

template<typename **F**, typename ...**Ts**>
bool *hpx*::**post**(*F* &&f, *Ts*&&... ts)

Runs the function `f` asynchronously (potentially in a separate thread which might be a part of a thread pool). This is done in a fire-and-forget manner, meaning there is no return value or way to synchronize with the function execution (it does not return an `hpx::future` that would hold the result of that function call).

`hpx::post` is particularly useful when synchronization mechanisms as heavyweight as futures are not desired, and instead, more lightweight mechanisms like latches or atomic variables are preferred. Essentially, the post function enables the launch of a new thread without the overhead of creating a future.

Note

`hpx::post` is similar to `hpx::async` but does not return a future. This is why there is no way of finding out the result/failure of the execution of this function.

---

[818] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

template<typename **Action**, typename **Target**, typename ...**Ts**>
bool `hpx::post`(*Action* &&action, *Target* &&target, *Ts*&&... ts)

The distributed implementation of `hpx::post` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID.

Template Parameters

- **`Action`** – The type of action instance
- **`Target`** – The type of target where the action should be executed
- **`Ts`** – The type of any additional arguments

Parameters

- **`action`** – The action instance to be executed
- **`target`** – The target where the action should be executed
- **`ts`** – Additional arguments

Returns

`true` if the action was successfully posted, `false` otherwise.

hpx::launch

Defined in header hpx/future.hpp[819].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **`launch`** : public detail::policy_holder<>

Launch policies for *hpx::async* etc.

hpx::async

Defined in header hpx/future.hpp[820].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::async (distributed)

template<typename **Action**, typename **F**, typename ...**Ts**>
auto `hpx::async`(*F* &&f, *Ts*&&... ts) -> decltype(detail::async_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *async* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a hpx::future that will eventually hold the result of that function call. If no policy is defined, *async* behaves as if it is called with policy being *hpx::launch::async* | hpx::launch::deferred. Otherwise, it calls a function *f* with arguments *ts* according to a specific launch policy.

---

[819] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp
[820] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

- If the async flag is set (i.e. (policy & hpx::launch::async) != 0), then async executes the callable object f on a new thread of execution (with all thread-locals initialized) as if spawned by *hpx::thread*(std::forward<F>(f), std::forward<Ts>(ts)…), except that if the function f returns a value or throws an exception, it is stored in the shared state accessible through the *hpx::future* that async returns to the caller.
- If the deferred flag is set (i.e. (policy & hpx::launch::deferred) != 0), then async converts f and ts… the same way as by *hpx::thread* constructor, but does not spawn a new thread of execution. Instead, lazy evaluation is performed: the first call to a non-timed wait function on the *hpx::future* that async returned to the caller will cause the copy of f to be invoked (as a rvalue) with the copies of ts… (also passed as rvalues) in the current thread (which does not have to be the thread that originally called hpx::async). The result or exception is placed in the shared state associated with the future and only then it is made ready. All further accesses to the same *hpx::future* will return the result immediately.
- If neither hpx::launch::async nor hpx::launch::deferred, nor any implementation-defined policy flag is set in policy, the behavior is undefined.

If more than one flag is set, it is implementation-defined which policy is selected. For the default (both the hpx::launch::async and hpx::launch::deferred flags are set in policy), standard recommends (but doesn't require) utilizing available concurrency, and deferring any additional tasks.

In any case, the call to hpx::async synchronizes-with (as defined in std::memory_order) the call to f, and the completion of f is sequenced-before making the shared state ready. If the async policy is chosen, the associated thread completion synchronizes-with the successful return from the first function that is waiting on the shared state, or with the return of the last function that releases the shared state, whichever comes first. If std::decay<Function>::type or each type in std::decay<Ts>::type is not constructible from its corresponding argument, the program is ill-formed.

Parameters

- **`f`** – Callable object to call
- **`ts`** – parameters to pass to f

Returns

hpx::future referring to the shared state created by this call to *hpx::async*.

template<typename **`Action`**, typename **`F`**, typename ...**`Ts`**>
auto `hpx::`**`async`**`(`*F* &&f, *Ts*&&... ts`)` -> decltype(detail::async_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *async* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a hpx::future that will eventually hold the result of that function call. If no policy is defined, *async* behaves as if it is called with policy being *hpx::launch::async* | hpx::launch::deferred. Otherwise, it calls a function *f* with arguments *ts* according to a specific launch policy.

- If the async flag is set (i.e. (policy & hpx::launch::async) != 0), then async executes the callable object f on a new thread of execution (with all thread-locals initialized) as if spawned by *hpx::thread*(std::forward<F>(f), std::forward<Ts>(ts)…), except that if the function f returns a value or throws an exception, it is stored in the shared state accessible through the *hpx::future* that async returns to the caller.
- If the deferred flag is set (i.e. (policy & hpx::launch::deferred) != 0), then async converts f and ts… the same way as by *hpx::thread* constructor, but does not spawn a new thread of execution. Instead, lazy evaluation is performed: the first call to a non-timed wait function on the *hpx::future* that async returned to the caller will cause the copy of f to be invoked (as a rvalue) with the copies of ts… (also passed as rvalues) in the current thread (which does not have to be the thread that originally called hpx::async). The result or exception is placed in the shared state associated with the future and only then it is made ready. All further accesses to the same *hpx::future* will return the result immediately.
- If neither hpx::launch::async nor hpx::launch::deferred, nor any implementation-defined policy flag is set in policy, the behavior is undefined.

If more than one flag is set, it is implementation-defined which policy is selected. For the default (both the hpx::launch::async and hpx::launch::deferred flags are set in policy), standard recommends (but doesn't require) utilizing available concurrency, and deferring any additional tasks.

In any case, the call to hpx::async synchronizes-with (as defined in std::memory_order) the call to f, and the completion of f is sequenced-before making the shared state ready. If the async policy is chosen, the associated thread completion synchronizes-with the successful return from the first function that is waiting on the shared state, or with the return of the last function that releases the shared state, whichever comes first. If std::decay<Function>::type or each type in std::decay<Ts>::type is not constructible from its corresponding argument, the program is ill-formed.

Parameters

- **`f`** – Callable object to call
- **`ts`** – parameters to pass to f

Returns

hpx::future referring to the shared state created by this call to *hpx::async*.

Warning

doxygenfunction: Unable to resolve function "hpx::async" with arguments (Executor&&, hpx::sycl::experimental::sycl_executor::queue_function_ptr_t<Ts…>&&, Ts&&…) in doxygen xml output for project "hpx" from directory: ../hpx_autodoc. Potential matches:

```
- template<typename Action, typename F, typename ...Ts> auto async(F &&f, Ts&&... ts)␣
↪-> decltype(detail::async_action_dispatch<Action, std::decay_t<F>>
↪::call(std::forward<F>(f), std::forward<Ts>(ts)...))
- template<typename Action, typename Target, typename ...Ts> auto async(Action &&
↪action, Target &&target, Ts&&... ts)
- template<typename Executor, typename ...Ts> decltype(auto) async(Executor &&exec,␣
↪hpx::sycl::experimental::sycl_executor::queue_function_ptr_t<Ts...> &&f, Ts&&... ts)
- template<typename F, typename ...Ts> decltype(auto) async(F &&f, Ts&&... ts)
```

template<typename **`Action`**, typename **`Target`**, typename ...**`Ts`**>
auto *`hpx`*`::`**`async`**`(`*Action* &&action, *Target* &&target, *Ts*&&... ts)

The distributed implementation of `hpx::async` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID. The action executes asynchronously.

Template Parameters

- **`Action`** – The type of action instance
- **`Target`** – The type of target where the action should be executed
- **`Ts`** – The type of any additional arguments

Parameters

- **`action`** – The action instance to be executed
- **`target`** – The target where the action should be executed
- **`ts`** – Additional arguments

Returns

`hpx::future` referring to the shared state created by this call to `hpx::async`

hpx::dataflow

Defined in header hpx/future.hpp[821].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

async_combinators

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/async_combinators/split_future.hpp

Defined in header hpx/async_combinators/split_future.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

---

[821] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

Functions

template<typename ...**Ts**>
inline *tuple*<*future*<*Ts*>...> **split_future**(*future*<*tuple*<*Ts*...>> &&f)

The function *split_future* is an operator allowing to split a given future of a sequence of values (any tuple, std::pair, or std::array) into an equivalent container of futures where each future represents one of the values from the original future. In some sense this function provides the inverse operation of *when_all*.

> **Note**
>
> The following cases are special:
>
> ```
> tuple<future<void> > split_future(future<tuple<> > && f);
> array<future<void>, 1> split_future(future<array<T, 0> > && f);
> ```
>
> here the returned futures are directly representing the futures which were passed to the function.

> **Note**
>
> Passing an invalid future to split_future does not throw immediately. Instead, it returns futures that carry an `hpx::error::no_state` exception, which will throw upon calling `.get()`.

Parameters

f – [in] A future holding an arbitrary sequence of values stored in a tuple-like container. This facility supports *hpx::tuple<>*, *std::pair<T1, T2>*, and *std::array<T, N>*

Returns

Returns an equivalent container (same container type as passed as the argument) of futures, where each future refers to the corresponding value in the input parameter. All the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

template<typename **T**>
inline *std*::vector<*future*<*T*>> **split_future**(*future*<*std*::vector<*T*>> &&f, *std*::size_t size)

The function *split_future* is an operator allowing to split a given future of a sequence of values (any std::vector) into a std::vector of futures where each future represents one of the values from the original std::vector. In some sense this function provides the inverse operation of *when_all*.

Parameters

- **f** – [in] A future holding an arbitrary sequence of values stored in a std::vector.
- **size** – [in] The number of elements the vector will hold once the input future has become ready

Returns

Returns a std::vector of futures, where each future refers to the corresponding value in the input parameter. All the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

hpx::when_some

Defined in header hpx/future.hpp[822].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InputIter**, typename **Container** = vector<*future*<typename *std*::iterator_traits<*InputIter*>::value_type>>>
future<when_some_result<*Container*>> `hpx::when_some`(*std*::size_t n, Iterator first, Iterator last)

The function *when_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

> **Note**
>
> The future returned by the function *when_some* becomes ready when at least *n* argument futures have become ready.

> **Note**
>
> Calling this version of *when_some* where first == last, returns a future with an empty container that is immediately ready. Each future and *shared_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when_some* will not throw an exception, but the futures held in the output collection may.

Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *when_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or shared_future objects for which *when_all* should wait.

Returns

Returns a when_some_result holding the same list of futures as has been passed to when_some and indices pointing to ready futures.

- future<when_some_result<Container<future<R>>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename **Range**>
future<when_some_result<*Range*>> `hpx::when_some`(*std*::size_t n, *Range* &&futures)

The function *when_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

---

[822] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

Note

The future returned by the function *when_some* becomes ready when at least *n* argument futures have become ready.

Note

Each future and *shared_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when_some* will not throw an exception, but the futures held in the output collection may.

Parameters

- **`n`** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **`futures`** – [in] A container holding an arbitrary amount of *future* or shared_future objects for which *when_some* should wait.

Returns

Returns a when_some_result holding the same list of futures as has been passed to when_some and indices pointing to ready futures.

- future<when_some_result<Container<future<R>>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename ...**Ts**>
future<when_some_result<*tuple*<*future*<T>...>>> `hpx::`**`when_some`**(*std*::size_t n, *Ts*&&... futures)

The function *when_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

Note

The future returned by the function *when_some* becomes ready when at least *n* argument futures have become ready.

Note

Each future and *shared_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when_some* will not throw an exception, but the futures held in the output collection may.

Parameters

- **`n`** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **`futures`** – [in] An arbitrary number of *future* or shared_future objects, possibly holding different types for which *when_some* should wait.

Returns

Returns a when_some_result holding the same list of futures as has been passed to when_some and an index pointing to a ready future..

- future<when_some_result<tuple<future<T0>, future<T1>…>>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- future<when_some_result<tuple<>>> if *when_some* is called with zero arguments. The returned future will be initially ready.

hpx::when_each

Defined in header hpx/future.hpp[823].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **F**, typename **Future**>
future<void> `hpx::when_each`(*F* &&f, *std*::vector<*Future*> &&futures)

The function *when_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

> **Note**
>
> This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – A vector holding an arbitrary amount of *future* or shared_future objects for which *wait_each* should wait.

Returns

Returns a future representing the event of all input futures being ready.

template<typename **F**, typename **Iterator**>
future<*Iterator*> `hpx::when_each`(*F* &&f, *Iterator* begin, *Iterator* end)

The function *when_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

> **Note**
>
> This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

---

[823] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

Parameters

- `f` – The function which will be called for each of the input futures once the future has become ready.
- `begin` – The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *wait_each* should wait.
- `end` – The iterator pointing to the last element of a sequence of *future* or shared_future objects for which *wait_each* should wait.

Returns

Returns a future representing the event of all input futures being ready.

template<typename **F**, typename ...**Ts**>
future<void> `hpx::when_each`(*F* &&f, *Ts*&&... futures)

The function *when_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

> **Note**
>
> This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

Parameters

- `f` – The function which will be called for each of the input futures once the future has become ready.
- `futures` – An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_each* should wait.

Returns

Returns a future representing the event of all input futures being ready.

hpx::wait_all

Defined in header hpx/future.hpp[824].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::wait_all_nothrow*
- *hpx::wait_all_n*
- *hpx::wait_all_n_nothrow*

template<typename **InputIter**>

---

[824] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

void *hpx*::**wait_all**(*InputIter* first, *InputIter* last)

The function *wait_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note

The function *wait_all* returns after all futures have become ready. All input futures are still valid after *wait_all* returns.

Note

The function wait_all will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_all_nothrow* instead.

Note

The caller is responsible for keeping the *futures* container alive, unmoved, and unmodified until wait_all returns and all inspection of the futures is complete.

Parameters

- **first** – The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *wait_all* should wait.
- **last** – The iterator pointing to the element after the last one of a sequence of *future* or shared_future objects for which *wait_all* should wait.

template<typename **R**>
void *hpx*::**wait_all**(*std*::vector<*future*<*R*>> &&futures)

The function *wait_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note

The function *wait_all* returns after all futures have become ready. All input futures are still valid after *wait_all* returns.

Note

The function wait_all will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_all_nothrow* instead.

Note

The caller is responsible for keeping the *futures* container alive, unmoved, and unmodified until wait_all returns and all inspection of the futures is complete.

Parameters

`futures` – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all* should wait.

template<typename **R**, *std*::size_t **N**>
void *hpx*::**`wait_all`**(*std*::array<*future*<*R*>, *N*> &&futures)

The function *wait_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note

The function *wait_all* returns after all futures have become ready. All input futures are still valid after *wait_all* returns.

Note

The function wait_all will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_all_nothrow* instead.

Note

The caller is responsible for keeping the *futures* container alive, unmoved, and unmodified until wait_all returns and all inspection of the futures is complete.

Parameters

`futures` – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all* should wait.

template<typename **T**>
void *hpx*::**`wait_all`**(*hpx*::*future*<*T*> const &f)

The function *wait_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note

The function *wait_all* returns after the future has become ready. The input future is still valid after *wait_all* returns.

Note

The function wait_all will rethrow any exceptions captured by the future while becoming ready. If this behavior is undesirable, use *wait_all_nothrow* instead.

Parameters

`f` – A *future* or shared_future for which *wait_all* should wait.

template<typename ...**T**>

void `hpx::wait_all`(*T*&&... futures)

The function *wait_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note

The function *wait_all* returns after all futures have become ready. All input futures are still valid after *wait_all* returns.

Note

The function wait_all will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_all_nothrow* instead.

Parameters

`futures` – An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_all* should wait.

hpx::wait_all_nothrow

Defined in header hpx/future.hpp[825].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::wait_all*
- *hpx::wait_all_n*
- *hpx::wait_all_n_nothrow*

template<typename **InputIter**>
bool `hpx::wait_all_nothrow`(*InputIter* first, *InputIter* last)

The function *wait_all_nothrow* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing, similar to *wait_all*. It differs from *wait_all* in that it will not rethrow any exceptions captured by the given futures while they became ready.

Note

The function *wait_all_nothrow* returns after all futures have become ready. All input futures are still valid after *wait_all_nothrow* returns.

Note

Unlike *wait_all*, this function will not rethrow any exceptions captured by the futures while becoming ready. Any such exceptions are not rethrown by this call; the caller can use the returned *bool* to detect their presence.

---

[825] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

Note

The caller is responsible for keeping the *futures* container alive, unmoved, and unmodified until wait_all returns and all inspection of the futures is complete.

Parameters

- `first` – The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *wait_all_nothrow* should wait.
- `last` – The iterator pointing to the element after the last one of a sequence of *future* or shared_future objects for which *wait_all_nothrow* should wait.

Returns

Returns *true* if any of the given futures held an exception once it became ready, and *false* otherwise.

template<typename `R`>
bool *hpx*::**wait_all_nothrow**(*std*::vector<*future*<*R*>> &&futures)

The function *wait_all_nothrow* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing, similar to *wait_all*. It differs from *wait_all* in that it will not rethrow any exceptions captured by the given futures while they became ready.

Note

The function *wait_all_nothrow* returns after all futures have become ready. All input futures are still valid after *wait_all_nothrow* returns.

Note

Unlike *wait_all*, this function will not rethrow any exceptions captured by the futures while becoming ready. Any such exceptions are not rethrown by this call; the caller can use the returned *bool* to detect their presence.

Parameters

`futures` – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all_nothrow* should wait.

Returns

Returns *true* if any of the given futures held an exception once it became ready, and *false* otherwise.

template<typename `R`, *std*::size_t `N`>
bool *hpx*::**wait_all_nothrow**(*std*::array<*future*<*R*>, *N*> &&futures)

The function *wait_all_nothrow* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing, similar to *wait_all*. It differs from *wait_all* in that it will not rethrow any exceptions captured by the given futures while they became ready.

Note

The function *wait_all_nothrow* returns after all futures have become ready. All input futures are still valid after *wait_all_nothrow* returns.

Note

Unlike *wait_all*, this function will not rethrow any exceptions captured by the futures while becoming ready. Any such exceptions are not rethrown by this call; the caller can use the returned *bool* to detect their presence.

Parameters

`futures` – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all_nothrow* should wait.

Returns

Returns *true* if any of the given futures held an exception once it became ready, and *false* otherwise.

template<typename **T**>
bool *hpx*::**wait_all_nothrow**(*hpx*::*future*<*T*> const &f)

The function *wait_all_nothrow* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing, similar to *wait_all*. It differs from *wait_all* in that it will not rethrow any exceptions captured by the given future while it became ready.

Note

The function *wait_all_nothrow* returns after the future has become ready. The input future is still valid after *wait_all_nothrow* returns.

Note

Unlike *wait_all*, this function will not rethrow any exception captured by the future while becoming ready. Any such exception is silently discarded; the caller can use the returned *bool* to detect its presence.

Parameters

`f` – A *future* or shared_future for which *wait_all_nothrow* should wait.

Returns

Returns *true* if the given future held an exception once it became ready, and *false* otherwise.

template<typename ...**T**>
bool *hpx*::**wait_all_nothrow**(*T*&&... futures)

The function *wait_all_nothrow* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing, similar to *wait_all*. It differs from *wait_all* in that it will not rethrow any exceptions captured by the given futures while they became ready.

Note

The function *wait_all_nothrow* returns after all futures have become ready. All input futures are still valid after *wait_all_nothrow* returns.

Note

Unlike *wait_all*, this function will not rethrow any exceptions captured by the futures while becoming ready. Any such exceptions are not rethrown by this call; the caller can use the returned *bool* to detect their presence.

Parameters

`futures` – An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_all_nothrow* should wait.

Returns

Returns *true* if any of the given futures held an exception once it became ready, and *false* otherwise.

hpx::wait_all_n

Defined in header hpx/future.hpp[826].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::wait_all*
- *hpx::wait_all_nothrow*
- *hpx::wait_all_n_nothrow*

template<typename **InputIter**>
void *hpx*::**wait_all_n**(*InputIter* begin, *std*::size_t count)

The function *wait_all_n* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note

The function *wait_all_n* returns after all futures have become ready. All input futures are still valid after *wait_all_n* returns.

Note

The function wait_all_n will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_all_n_nothrow* instead.

Note

The caller is responsible for keeping the *futures* container alive, unmoved, and unmodified until wait_all returns and all inspection of the futures is complete.

Parameters

- `begin` – The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *wait_all_n* should wait.
- `count` – The number of elements in the sequence starting at *first*.

---

[826] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

Returns
The function *wait_all_n* will return an iterator referring to the first element in the input sequence after the last processed element.

hpx::wait_all_n_nothrow

Defined in header hpx/future.hpp[827].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::wait_all*
- *hpx::wait_all_nothrow*
- *hpx::wait_all_n*

template<typename **InputIter**>
std::pair<*InputIter*, bool> **hpx::wait_all_n_nothrow**(*InputIter* begin, *std*::size_t count)

The function *wait_all_n_nothrow* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing, similar to *wait_all_n*. It differs from *wait_all_n* in that it will not rethrow any exceptions captured by the given futures while they became ready.

Note

The function *wait_all_n_nothrow* returns after all futures have become ready. All input futures are still valid after *wait_all_n_nothrow* returns.

Note

Unlike *wait_all_n*, this function will not rethrow any exceptions captured by the futures while becoming ready. Any such exceptions are not rethrown by this call; the caller can use the returned *bool* to detect their presence.

Note

The caller is responsible for keeping the *futures* container alive, unmoved, and unmodified until wait_all returns and all inspection of the futures is complete.

Parameters

- **begin** – The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *wait_all_n_nothrow* should wait.
- **count** – The number of elements in the sequence starting at *first*.

Returns
The function *wait_all_n_nothrow* returns a pair consisting of an iterator referring to the first element in the input sequence after the last processed element, and a *bool* that is *true* if any of the given futures held an exception once it became ready, and *false* otherwise.

---

[827] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

hpx::wait_each

Defined in header hpx/future.hpp[828].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::wait_each_n_nothrow*

template<typename **F**, typename **Future**>
void hpx::**wait_each**(*F* &&f, *std*::vector<*Future*> &&futures)

The function *wait_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait_each* returns after all futures have been become ready.

> **Note**
>
> This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.
- **futures** – A vector holding an arbitrary amount of *future* or shared_future objects for which *wait_each* should wait.

template<typename **F**, typename **Iterator**>
void hpx::**wait_each**(*F* &&f, *Iterator* begin, *Iterator* end)

The function *wait_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait_each* returns after all futures have been become ready.

> **Note**
>
> This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

Parameters

- **f** – The function which will be called for each of the input futures once the future has become ready.

---

[828] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

- **`begin`** – The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *wait_each* should wait.
- **`end`** – The iterator pointing to the last element of a sequence of *future* or shared_future objects for which *wait_each* should wait.

template<typename **`F`**, typename ...**`T`**>
void *`hpx`*`::`**`wait_each`**`(`*F* &&f, *T*&&... futures)

The function *wait_each* is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. *wait_each* returns after all futures have been become ready.

Note

This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a *future* to be processed or a type that *std::size_t* is implicitly convertible to as the first parameter and the *future* as the second parameter. The first parameter will correspond to the index of the current *future* in the collection.

Parameters

- **`f`** – The function which will be called for each of the input futures once the future has become ready.
- **`futures`** – An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_each* should wait.

- *hpx::wait_some_n_nothrow*

template<typename **InputIter**>
void *hpx*::**wait_some**(*std*::size_t n, *InputIter* first, *InputIter* last)

The function *wait_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

> **Note**
>
> The function *wait_some* returns after *n* futures have become ready. All input futures are still valid after *wait_some* returns.

> **Note**
>
> The function wait_some will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_some_nothrow* instead.

Parameters

- **n** – [in] The number of futures out of the arguments which have to become ready in order for the function to return.
- **first** – [in] The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *when_all* should wait.
- **last** – [in] The iterator pointing to the last element of a sequence of *future* or shared_future objects for which *when_all* should wait.

template<typename **R**>
void *hpx*::**wait_some**(*std*::size_t n, *std*::vector<*future*<*R*>> &&futures)

The function *wait_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

> **Note**
>
> The function *wait_some* returns after *n* futures have become ready. All input futures are still valid after *wait_some* returns.

> **Note**
>
> The function wait_some will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_some_nothrow* instead.

Parameters

- **`n`** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **`futures`** – [in] A vector holding an arbitrary amount of *future* or shared_future objects for which *wait_some* should wait.

template<typename **R**, *std*::size_t **N**>
void *hpx*::**wait_some**(*std*::size_t n, *std*::array<*future*<*R*>, *N*> &&futures)

The function *wait_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

> **Note**
>
> The function *wait_some* returns after *n* futures have become ready. All input futures are still valid after *wait_some* returns.

> **Note**
>
> The function wait_some will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_some_nothrow* instead.

Parameters

- **`n`** – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **`futures`** – [in] An array holding an arbitrary amount of *future* or shared_future objects for which *wait_some* should wait.

template<typename ...**T**>
void *hpx*::**wait_some**(*std*::size_t n, *T*&&... futures)

The function *wait_some* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

> **Note**
>
> The function *wait_all* returns after *n* futures have become ready. All input futures are still valid after *wait_some* returns.

> **Note**
>
> The function wait_some will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_some_nothrow* instead.

Parameters

- `n` – [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- `futures` – [in] An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_some* should wait.

hpx::wait_some_nothrow

Defined in header hpx/future.hpp[833].

Warning

doxygenfunction: Cannot find function "hpx::wait_some_n_nothrow" in doxygen xml output for project "hpx" from directory: ../hpx_autodoc

hpx::when_any

Defined in header hpx/future.hpp[836].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InputIter**, typename **Container** = vector<*future*<typename *std*::iterator_traits<*InputIter*>::value_type>>>
future<when_any_result<*Container*>> **hpx::when_any**(*InputIter* first, *InputIter* last)

function *when_any* creates a future object that becomes when at least one element in a set of *future* and shared_future objects becomes ready. It is a non-deterministic choice operator. It OR-composes all given future objects and returns a new future object representing the same list of futures after one future of that list finishes execution.

---

[835] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

[836] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

Parameters

- **`first`** – [in] The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *when_any* should wait.
- **`last`** – [in] The iterator pointing to the last element of a sequence of *future* or shared_future objects for which *when_any* should wait.

Returns

Returns a when_any_result holding the same list of futures as has been passed to when_any and an index pointing to a ready future.

- future<when_any_result<Container<future<R>>>>: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename **Range**>
future<when_any_result<*Range*>> `hpx::`**`when_any`**(*Range* &values)

function *when_any* creates a future object that becomes when at least one element in a set of *future* and shared_future objects becomes ready. It is a non-deterministic choice operator. It OR-composes all given future objects and returns a new future object representing the same list of futures after one future of that list finishes execution.

Parameters

`values` – [in] A range holding an arbitrary amount of *futures* or shared_future objects for which *when_any* should wait.

Returns

Returns a when_any_result holding the same list of futures as has been passed to when_any and an index pointing to a ready future.

- future<when_any_result<Container<future<R>>>>: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename ...**T**>
future<when_any_result<*tuple*<*future*<*T*>...>>> `hpx::`**`when_any`**(*T*&&... futures)

function *when_any* creates a future object that becomes when at least one element in a set of *future* and shared_future objects becomes ready. It is a non-deterministic choice operator. It OR-composes all given future objects and returns a new future object representing the same list of futures after one future of that list finishes execution.

Parameters

`futures` – [in] An arbitrary number of *future* or shared_future objects, possibly holding different types for which *when_any* should wait.

Returns

Returns a when_any_result holding the same list of futures as has been passed to when_any and an index pointing to a ready future.

- future<when_any_result<tuple<future<T0>, future<T1>…>>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- future<when_any_result<tuple<>>> if *when_any* is called with zero arguments. The returned future will be initially ready.

hpx::wait_any

Defined in header hpx/future.hpp[837].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Parameters

futures – [in] A vector holding an arbitrary amount of *future* or shared_future objects for which *wait_any* should wait.

template<typename **R**, *std*::size_t **N**>
void *hpx*::**wait_any**(*std*::array<*future*<*R*>, *N*> &futures)

The function *wait_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

> **Note**
>
> The function *wait_any* returns after at least one future has become ready. All input futures are still valid after *wait_any* returns.

> **Note**
>
> The function wait_any will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_any_nothrow* instead.

Parameters

futures – [in] Amn array holding an arbitrary amount of *future* or shared_future objects for which *wait_any* should wait.

template<typename ...**T**>
void *hpx*::**wait_any**(*T*&&... futures)

The function *wait_any* is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

> **Note**
>
> The function *wait_any* returns after at least one future has become ready. All input futures are still valid after *wait_any* returns.

> **Note**
>
> The function wait_any will rethrow any exceptions captured by the futures while becoming ready. If this behavior is undesirable, use *wait_any_nothrow* instead.

Parameters

futures – [in] An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_any* should wait.

hpx::wait_any_nothrow

Defined in header hpx/future.hpp[838].

Warning

doxygenfunction: Cannot find function "hpx::wait_any_n_nothrow" in doxygen xml output for project "hpx" from directory: ../hpx_autodoc

hpx::when_all

Defined in header hpx/future.hpp[841].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **InputIter**, typename **Container** = vector<*future*<typename *std*::iterator_traits<*InputIter*>::value_type>>>
hpx::*future*<*Container*> **hpx::when_all**(*InputIter* first, *InputIter* last)

function *when_all* creates a future object that becomes ready when all elements in a set of *future* and shared_future objects become ready. It is an operator allowing to join on the result of all given futures. It AND-composes all given future objects and returns a new future object representing the same list of futures after they finished executing.

Note

Calling this version of *when_all* where first == last, returns a future with an empty container that is immediately ready. Each future and *shared_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when_all* will not throw an exception, but the futures held in the output collection may.

Parameters

- **`first`** – [in] The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *when_all* should wait.
- **`last`** – [in] The iterator pointing to the last element of a sequence of *future* or shared_future objects for which *when_all* should wait.

Returns

Returns a future holding the same list of futures as has been passed to *when_all*.

---

[840] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp
[841] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

- future<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all have the same type. The order of the futures in the output container will be the same as given by the input iterator.

template<typename **Range**>
hpx::*future*<*Range*> `hpx::when_all`(*Range* &&values)

function *when_all* creates a future object that becomes ready when all elements in a set of *future* and shared_future objects become ready. It is an operator allowing to join on the result of all given futures. It AND-composes all given future objects and returns a new future object representing the same list of futures after they finished executing.

Note

Calling this version of *when_all* where the input container is empty, returns a future with an empty container that is immediately ready. Each future and *shared_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when_all* will not throw an exception, but the futures held in the output collection may.

Parameters

values – [in] A range holding an arbitrary amount of *future* or shared_future objects for which *when_all* should wait.

Returns

Returns a future holding the same list of futures as has been passed to when_all.

- future<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all have the same type.

template<typename ...**T**>
hpx::*future*<*hpx*::*tuple*<*hpx*::*future*<*T*>...>> `hpx::when_all`(*T*&&... futures)

function *when_all* creates a future object that becomes ready when all elements in a set of *future* and shared_future objects become ready. It is an operator allowing to join on the result of all given futures. It AND-composes all given future objects and returns a new future object representing the same list of futures after they finished executing.

Note

Each future and *shared_future* is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by *when_all* will not throw an exception, but the futures held in the output collection may.

Parameters

futures – [in] An arbitrary number of *future* or shared_future objects, possibly holding different types for which *when_all* should wait.

Returns

Returns a future holding the same list of futures as has been passed to *when_all*.

- future<tuple<future<T0>, future<T1>, future<T2>…>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- future<tuple<>> if *when_all* is called with zero arguments. The returned future will be initially ready.

hpx::wait_all_for

Defined in header hpx/future.hpp[842].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

template<typename **InputIter**>
hpx::future_status **hpx::wait_all_for**(*hpx*::chrono::*steady_duration* const &timeout, *InputIter* first, *InputIter* last)

The function *wait_all_for* is an operator allowing to join on the result of all given futures, similar to *wait_all*. It differs from *wait_all* in that it will not suspend indefinitely if one or more of the given futures never become ready; instead it returns as soon as either all futures have become ready, or the given timeout has elapsed, whichever happens first.

> **Note**
>
> The function *wait_all_for* returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after *wait_all_for* returns, independently of the returned status, and can be inspected (e.g. using *is_ready()*) to determine which of the given futures have become ready.

> **Note**
>
> The function wait_all_for will rethrow any exceptions captured by the futures while becoming ready, as long as all the given futures became ready before the timeout elapsed. If this behavior is undesirable, use *wait_all_for_nothrow* instead.

Parameters

- **`timeout`** – The maximum duration to wait for all the given futures to become ready.
- **`first`** – The iterator pointing to the first element of a sequence of *future* or shared_future objects for which *wait_all_for* should wait.
- **`last`** – The iterator pointing to the element after the last one of a sequence of *future* or shared_future objects for which *wait_all_for* should wait.

Returns

Returns *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise.

template<typename **R**>
hpx::future_status **hpx::wait_all_for**(*hpx*::chrono::*steady_duration* const &timeout, *std*::vector<*future*<*R*>> const &futures)

The function *wait_all_for* is an operator allowing to join on the result of all given futures, similar to *wait_all*. It differs from *wait_all* in that it will not suspend indefinitely if one or more of the given futures never become ready;

---

[842] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

instead it returns as soon as either all futures have become ready, or the given timeout has elapsed, whichever happens first.

Note

The function *wait_all_for* returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after *wait_all_for* returns, independently of the returned status, and can be inspected (e.g. using *is_ready()*) to determine which of the given futures have become ready.

Note

The function wait_all_for will rethrow any exceptions captured by the futures while becoming ready, as long as all the given futures became ready before the timeout elapsed. If this behavior is undesirable, use *wait_all_for_nothrow* instead.

Note

The function wait_all_for returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after wait_all_for returns, independently of the returned status, and can be inspected (e.g. using is_ready()) to determine which of the given futures have become ready.

Note

The caller is responsible for keeping the *futures* container itself (and, for the iterator-range overload, the underlying sequence) alive, unmoved, and unmodified until it is done inspecting the futures' state. If the timeout expires before all futures become ready, wait_all_for may leave asynchronous continuations attached to the not-yet-ready futures; destroying, moving, or reallocating the container before those futures settle results in undefined behavior.

Parameters

- **`timeout`** – The maximum duration to wait for all the given futures to become ready.
- **`futures`** – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all_for* should wait.

Returns

Returns *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise.

template<typename **R**, *std*::size_t **N**>
hpx::future_status **`hpx::wait_all_for`**(*hpx*::chrono::*steady_duration* const &timeout, *std*::array<*future*<*R*>, *N*> const &futures)

The function *wait_all_for* is an operator allowing to join on the result of all given futures, similar to *wait_all*. It differs from *wait_all* in that it will not suspend indefinitely if one or more of the given futures never become ready; instead it returns as soon as either all futures have become ready, or the given timeout has elapsed, whichever happens first.

Note

The function *wait_all_for* returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after *wait_all_for* returns, independently of the returned status, and can be inspected (e.g. using *is_ready()*) to determine which of the given futures have become ready.

Note

The function wait_all_for will rethrow any exceptions captured by the futures while becoming ready, as long as all the given futures became ready before the timeout elapsed. If this behavior is undesirable, use *wait_all_for_nothrow* instead.

Note

The function wait_all_for returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after wait_all_for returns, independently of the returned status, and can be inspected (e.g. using is_ready()) to determine which of the given futures have become ready.

Note

The caller is responsible for keeping the *futures* container itself (and, for the iterator-range overload, the underlying sequence) alive, unmoved, and unmodified until it is done inspecting the futures' state. If the timeout expires before all futures become ready, wait_all_for may leave asynchronous continuations attached to the not-yet-ready futures; destroying, moving, or reallocating the container before those futures settle results in undefined behavior.

Parameters

- **`timeout`** – The maximum duration to wait for all the given futures to become ready.
- **`futures`** – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all_for* should wait.

Returns

Returns *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise.

template<typename **T**>
hpx::future_status **hpx::wait_all_for**(*hpx*::chrono::*steady_duration* const &timeout, *hpx*::*future*<*T*> const &f)

The function *wait_all_for* is an operator allowing to join on the result of the given future, similar to *wait_all*. It differs from *wait_all* in that it will not suspend indefinitely if the given future never becomes ready; instead it returns as soon as either the future has become ready, or the given timeout has elapsed, whichever happens first.

Note

The function *wait_all_for* returns after the future has become ready, or after the given timeout has expired, whichever comes first. The input future is still valid after *wait_all_for* returns, independently of the returned status.

Note

The function wait_all_for will rethrow any exceptions captured by the future while becoming ready, as long as the given future became ready before the timeout elapsed. If this behavior is undesirable, use *wait_all_for_nothrow* instead.

Parameters

- **`timeout`** – The maximum duration to wait for the given future to become ready.
- **`f`** – A *future* or shared_future for which *wait_all_for* should wait.

Returns

Returns *hpx::future_status::ready* if the given future has become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise.

template<typename ...**T**>
hpx::future_status **`hpx::wait_all_for`**(*hpx*::chrono::*steady_duration* const &timeout, *T* const&... futures)

The function *wait_all_for* is an operator allowing to join on the result of all given futures, similar to *wait_all*. It differs from *wait_all* in that it will not suspend indefinitely if one or more of the given futures never become ready; instead it returns as soon as either all futures have become ready, or the given timeout has elapsed, whichever happens first.

Note

The function *wait_all_for* returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after *wait_all_for* returns, independently of the returned status, and can be inspected (e.g. using *is_ready()*) to determine which of the given futures have become ready.

Note

The function wait_all_for will rethrow any exceptions captured by the futures while becoming ready, as long as all the given futures became ready before the timeout elapsed. If this behavior is undesirable, use *wait_all_for_nothrow* instead.

Parameters

- **`timeout`** – The maximum duration to wait for all the given futures to become ready.
- **`futures`** – An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_all_for* should wait.

Returns

Returns *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise.

hpx::wait_all_for_nothrow

Defined in header hpx/future.hpp[843].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

> The function wait_all_for_nothrow returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after wait_all_for returns, independently of the returned status, and can be inspected (e.g. using is_ready()) to determine which of the given futures have become ready.

> **Note**
>
> The caller is responsible for keeping the *futures* container itself (and, for the iterator-range overload, the underlying sequence) alive, unmoved, and unmodified until it is done inspecting the futures' state. If the timeout expires before all futures become ready, wait_all_for may leave asynchronous continuations attached to the not-yet-ready futures; destroying, moving, or reallocating the container before those futures settle results in undefined behavior.

Parameters

- **`timeout`** – The maximum duration to wait for all the given futures to become ready.
- **`futures`** – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all_for_nothrow* should wait.

Returns

Returns a *wait_all_for_nothrow_result* object whose *status* member is *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise; and whose *has_exceptional_results* member indicates whether any of the futures that became ready had captured an exception.

template<typename **R**, *std*::size_t **N**>
hpx::wait_all_for_nothrow_result **`hpx::wait_all_for_nothrow`**(*hpx*::chrono::*steady_duration* const &timeout, *std*::array<*future*<*R*>, *N*> const &futures)

The function *wait_all_for_nothrow* is an operator allowing to join on the result of all given futures, similar to *wait_all_for*. It differs from *wait_all_for* in that it will not rethrow any exceptions captured by the given futures while they became ready; instead it returns as soon as either all futures have become ready, or the given timeout has elapsed, whichever happens first.

Note

The function *wait_all_for_nothrow* returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after *wait_all_for_nothrow* returns, independently of the returned status, and can be inspected (e.g. using *is_ready()*) to determine which of the given futures have become ready.

Note

Unlike *wait_all_for*, this function will not rethrow any exceptions captured by the futures while becoming ready. Any such exceptions are not rethrown by this call.

Note

The function wait_all_for_nothrow returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after wait_all_for returns, independently of the returned status, and can be inspected (e.g. using is_ready()) to determine which of the given futures have become ready.

Note

The caller is responsible for keeping the *futures* container itself (and, for the iterator-range overload, the underlying sequence) alive, unmoved, and unmodified until it is done inspecting the futures' state. If the timeout expires before all futures become ready, wait_all_for may leave asynchronous continuations attached to the not-yet-ready futures; destroying, moving, or reallocating the container before those futures settle results in undefined behavior.

Parameters

- **`timeout`** – The maximum duration to wait for all the given futures to become ready.
- **`futures`** – A vector or array holding an arbitrary amount of *future* or shared_future objects for which *wait_all_for_nothrow* should wait.

Returns

Returns a *wait_all_for_nothrow_result* object whose *status* member is *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise; and whose *has_exceptional_results* member indicates whether any of the futures that became ready had captured an exception.

template<typename **T**>
hpx::wait_all_for_nothrow_result **`hpx::wait_all_for_nothrow`**(*hpx*::chrono::*steady_duration* const &timeout, *hpx*::*future*<*T*> const &f)

The function *wait_all_for_nothrow* is an operator allowing to join on the result of the given future, similar to *wait_all_for*. It differs from *wait_all_for* in that it will not rethrow any exceptions captured by the given future while it became ready; instead it returns as soon as either the future has become ready, or the given timeout has elapsed, whichever happens first.

> **Note**
>
> The function *wait_all_for_nothrow* returns after the future has become ready, or after the given timeout has expired, whichever comes first. The input future is still valid after *wait_all_for_nothrow* returns, independently of the returned status.

> **Note**
>
> Unlike *wait_all_for*, this function will not rethrow any exceptions captured by the future while becoming ready. Any such exception is silently discarded.

Parameters

- `timeout` – The maximum duration to wait for the given future to become ready.
- `f` – A *future* or shared_future for which *wait_all_for_nothrow* should wait.

Returns

Returns a *wait_all_for_nothrow_result* object whose *status* member is *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise; and whose *has_exceptional_results* member indicates whether any of the futures that became ready had captured an exception.

template<typename ...**T**>
hpx::wait_all_for_nothrow_result **hpx::wait_all_for_nothrow**(*hpx*::chrono::*steady_duration* const &timeout, *T* const&... futures)

The function *wait_all_for_nothrow* is an operator allowing to join on the result of all given futures, similar to *wait_all_for*. It differs from *wait_all_for* in that it will not rethrow any exceptions captured by the given futures while they became ready; instead it returns as soon as either all futures have become ready, or the given timeout has elapsed, whichever happens first.

> **Note**
>
> The function *wait_all_for_nothrow* returns after all futures have become ready, or after the given timeout has expired, whichever comes first. All input futures are still valid after *wait_all_for_nothrow* returns, independently of the returned status, and can be inspected (e.g. using *is_ready()*) to determine which of the given futures have become ready.

> **Note**
>
> Unlike *wait_all_for*, this function will not rethrow any exceptions captured by the futures while becoming ready. Any such exceptions are not rethrown by this call.

Parameters

- `timeout` – The maximum duration to wait for all the given futures to become ready.

- **`futures`** – An arbitrary number of *future* or shared_future objects, possibly holding different types for which *wait_all_for_nothrow* should wait.

Returns

Returns a *wait_all_for_nothrow_result* object whose *status* member is *hpx::future_status::ready* if all the given futures have become ready before *timeout* has elapsed, and *hpx::future_status::timeout* otherwise; and whose *has_exceptional_results* member indicates whether any of the futures that became ready had captured an exception.

hpx::wait_all_for_n

Defined in header hpx/future.hpp[844].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

inline constexpr auto **operator()**(*F* &&f) const

async_sycl

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/async_sycl/sycl_executor.hpp

Defined in header hpx/async_sycl/sycl_executor.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

template<typename **Executor**, typename ...**Ts**>
decltype(auto) **async**(*Executor* &&exec, *hpx*::*sycl*::*experimental*::*sycl_executor*::*queue_function_ptr_t*<*Ts*...> &&f, *Ts*&&... ts)

hpx::async overload for launching sycl queue member functions with an sycl executor

template<typename **Executor**, typename ...**Ts**>
bool **apply**(*Executor* &&exec, *hpx*::*sycl*::*experimental*::*sycl_executor*::*queue_function_ptr_t*<*Ts*...> &&f, *Ts*&&... ts)

hpx::apply overload for launching sycl queue member functions with an sycl executor

namespace **execution**

namespace **experimental**

namespace **sycl**

namespace **experimental**

struct **sycl_executor**

Public Types

using **`future_type`** = *hpx*::*future*<void>

template<typename ...**`Params`**>

using **`queue_function_ptr_t`** = ::sycl::event (::sycl::queue::*)(*std*::conditional_t<*std*::is_trivial_v<*std*::remove_reference_t<*Params*>>, *std*::decay_t<*Params*>, *Params*>...)

Default Implementation without the extra intel code_location parameter. Removes the reference for trivial types to make the function matching easier (see sycl_stream.cpp test)

Public Functions

template<typename **`sycl_device_selector`**>
inline explicit **`sycl_executor`**(*sycl_device_selector* const &selector)

Create a SYCL executor (based on a sycl queue)

`~sycl_executor`() = default

inline *future_type* **`get_future`**()

Get future for this command_queue (NOTE will be more efficient if an event is provided &#8212; otherwise a dummy kernel must be submitted to get an event)

inline *future_type* **`get_future`**(::sycl::event event)

Get future for that becomes ready when the given event completes.

template<typename ...**`Params`**>
inline void **`post`**(*queue_function_ptr_t*<*Params*...> &&queue_member_function, *Params*&&... args)

Invoke queue member function given queue and parameters &#8212; do not use event to return a hpx::future (One way)

template<typename ...**`Params`**>
inline *hpx*::*future*<void> **`async_execute`**(*queue_function_ptr_t*<*Params*...> &&queue_member_function, *Params*&&... args)

Invoke queue member function given queue and parameters &#8212; hpx::future tied to the sycl event / (two way)

inline ::sycl::device **`get_device`**() const

Return the device used by the underlying SYCL queue.

inline ::sycl::context **`get_context`**() const

Return the context used by the underlying SYCL queue.

inline ::sycl::queue &**`get_queue`**()

Return the underlying queue for direct access.

Protected Attributes

::sycl::queue **command_queue**

cache

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/cache/local_cache.hpp

Defined in header hpx/cache/local_cache.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **cache**

template<typename **Key**, typename **Entry**, typename **UpdatePolicy** = *std*::less<*Entry*>, typename **InsertPolicy** = policies::always<*Entry*>, typename **CacheStorage** = *std*::map<*Key*, *Entry*>, typename **Statistics** = *statistics*::*no_statistics*>
class **local_cache**

#include <hpx/cache/local_cache.hpp> The local_cache implements the basic functionality needed for a local (non-distributed) cache.

Template Parameters

- **Key** – The type of the keys to use to identify the entries stored in the cache
- **Entry** – The type of the items to be held in the cache, must model the CacheEntry concept
- **UpdatePolicy** – A (optional) type specifying a (binary) function object used to sort the cache entries based on their ‘age’. The ‘oldest’ entries (according to this sorting criteria) will be discarded first if the maximum capacity of the cache is reached. The default is std::less<Entry>. The function object will be invoked using 2 entry instances of the type *Entry*. This type must model the UpdatePolicy model.
- **InsertPolicy** – A (optional) type specifying a (unary) function object used to allow global decisions whether a particular entry should be added to the cache or not. The default is *policies::always*, imposing no global insert related criteria on the cache. The function object will be invoked using the entry instance to be inserted into the cache. This type must model the InsertPolicy model.
- **CacheStorage** – A (optional) container type used to store the cache items. The container must be an associative and STL compatible container.The default is a std::map<Key, Entry>.
- **Statistics** – A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type statistics::no_statistics which does not collect any numbers, but provides empty stubs allowing the code to compile.

Public Types

using **key_type** = *Key*

using **entry_type** = *Entry*

using **update_policy_type** = *UpdatePolicy*

using **insert_policy_type** = *InsertPolicy*

using **storage_type** = *CacheStorage*

using **statistics_type** = *Statistics*

using **value_type** = typename *entry_type*::value_type

using **size_type** = typename *storage_type*::size_type

using **storage_value_type** = typename *storage_type*::value_type

Public Functions

inline explicit **local_cache**(*size_type* max_size = 0, *update_policy_type* const &up = *update_policy_type*(), *insert_policy_type* const &ip = *insert_policy_type*())

Construct an instance of a *local_cache*.

Parameters

- **max_size** – [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry's *get_size* function.
- **up** – [in] An instance of the *UpdatePolicy* to use for this cache. The default is to use a default constructed instance of the type as defined by the *UpdatePolicy* template parameter.
- **ip** – [in] An instance of the *InsertPolicy* to use for this cache. The default is to use a default constructed instance of the type as defined by the *InsertPolicy* template parameter.

local_cache(*local_cache* const &other) = default

local_cache(*local_cache* &&other) = default

local_cache &**operator=**(*local_cache* const &other) = default

local_cache &**operator=**(*local_cache* &&other) = default

~local_cache() = default

inline constexpr *size_type* **size**() const noexcept

Return current size of the cache.

Returns

The current size of this cache instance.

inline constexpr *size_type* **capacity**() const noexcept

Access the maximum size the cache is allowed to grow to.

> **Note**
>
> The unit of this value is usually determined by the unit of the return values of the entry's function *entry::get_size*.

Returns

The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

inline bool **reserve**(*size_type* max_size)

Change the maximum size this cache can grow to.

Parameters

max_size – [in] The new maximum size this cache will be allowed to grow to.

Returns

This function returns *true* if successful. It returns *false* if the new *max_size* is smaller than the current limit and the cache could not be shrunk to the new maximum size.

inline bool **holds_key**(*key_type* const &k) const

Check whether the cache currently holds an entry identified by the given key.

> **Note**
>
> This function does not call the entry's function *entry::touch*. It just checks if the cache contains an entry corresponding to the given key.

Parameters

k – [in] The key for the entry which should be looked up in the cache.

Returns

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **get_entry**(*key_type* const &k, *key_type* &realkey, *entry_type* &val)

Get a specific entry identified by the given key.

> **Note**
>
> The function will call the entry's *entry::touch* function if the value corresponding to the provided key is found in the cache.

Parameters

- **k** – **[in]** The key for the entry which should be retrieved from the cache.
- **realkey** – **[out]** Return the full real key found in the cache
- **val** – **[out]** If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

Returns
This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **`get_entry`**(*key_type* const &k, *entry_type* &val)

Get a specific entry identified by the given key.

> **Note**
>
> The function will call the entry's *entry::touch* function if the value corresponding to the provided key is found in the cache.

Parameters
- **`k`** – [in] The key for the entry which should be retrieved from the cache.
- **`val`** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

Returns
This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **`get_entry`**(*key_type* const &k, *value_type* &val)

Get a specific entry identified by the given key.

> **Note**
>
> The function will call the entry's *entry::touch* function if the value corresponding to the provided is found in the cache.

Parameters
- **`k`** – [in] The key for the entry which should be retrieved from the cache
- **`val`** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding value.

Returns
This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **`insert`**(*key_type* const &k, *value_type* const &val)

Insert a new element into this cache.

> **Note**
>
> This function invokes both, the insert policy as provided to the constructor and the function *entry::insert* of the newly constructed entry instance. If either of these functions returns false the key/value pair doesn't get inserted into the cache and the *insert* function will return *false*. Other reasons for this function to fail (return *false*) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

Parameters
- **`k`** – [in] The key for the entry which should be added to the cache.
- **`val`** – [in] The value which should be added to the cache.

Returns
This function returns *true* if the entry has been successfully added to the cache, otherwise

it returns *false*.

inline bool **insert**(*key_type* const &k, *value_type* &&val)

template<typename **Entry_**, *std*::enable_if_t<*std*::is_convertible_v<*std*::decay_t<*Entry_*>, *entry_type*>, int> = 0>
inline bool **insert**(*key_type* const &k, *Entry_* &&e)

Insert a new entry into this cache.

> **Note**
>
> This function invokes both, the insert policy as provided to the constructor and the function *entry::insert* of the provided entry instance. If either of these functions returns false the key/value pair doesn't get inserted into the cache and the *insert* function will return *false*. Other reasons for this function to fail (return *false*) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

Parameters

- **k** – [in] The key for the entry which should be added to the cache.
- **e** – [in] The entry which should be added to the cache.

Returns

This function returns *true* if the entry has been successfully added to the cache, otherwise it returns *false*.

template<typename **Value**, *std*::enable_if_t<*std*::is_convertible_v<*std*::decay_t<*Value*>, *value_type*>, int> = 0>
inline bool **update**(*key_type* const &k, *Value* &&val)

Update an existing element in this cache.

> **Note**
>
> The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

> **Note**
>
> The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

Parameters

- **k** – [in] The key for the value which should be updated in the cache.
- **val** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

Returns

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

template<typename **F**, typename **Value**, typename =
std::enable_if_t<*std*::is_convertible_v<*std*::decay_t<*Value*>, *value_type*>>>

inline bool **`update_if`**(*key_type* const &k, *Value* &&val, *F* &&f)

Update an existing element in this cache.

> **Note**
>
> The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

> **Note**
>
> The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

Parameters

- **`k`** – [in] The key for the value which should be updated in the cache.
- **`val`** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- **`f`** – [in] A callable taking two arguments, *k* and the key found in the cache (in that order). If *f* returns true, then the update will continue. If *f* returns false, then the update will not succeed.

Returns

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

template<typename **`Entry_`**, *std*::enable_if_t<*std*::is_convertible_v<*std*::decay_t<*Entry_*>, *entry_type*>, int> = 0>
inline bool **`update`**(*key_type* const &k, *Entry_* &&e)

Update an existing entry in this cache.

> **Note**
>
> The function will call the entry's *entry::touch* function if the indexed value is found in the cache.

> **Note**
>
> The difference to the other overload of the *insert* function is that this overload replaces the whole cache entry, while the other overload replaces the cached value only, leaving the cache entry properties untouched.

> **Note**
>
> If the new entry is larger than the one it replaces, other entries may be evicted to keep the cache within its capacity. An entry larger than the capacity of the cache is rejected and the existing entry is kept.

Parameters

- **k** – [in] The key for the entry which should be updated in the cache.
- **e** – [in] The entry which should be used as a replacement for the existing entry in the cache. Any existing entry is first removed and then this entry is added.

Returns

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

template<typename **Func** = policies::always<*storage_value_type*>>
inline *size_type* **erase**(*Func* &&ep = *Func*())

Remove stored entries from the cache for which the supplied function object returns true.

Parameters

ep – [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is *true*. Even then the entry might not be removed from the cache as its *entry::remove* function might return false.

Returns

This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get_size* functions of the removed entries).

inline *size_type* **erase**()

Remove all stored entries from the cache.

Note

All entries are considered for removal, but in the end an entry might not be removed from the cache as its *entry::remove* function might return false. This function is very useful for instance in conjunction with an entry's *entry::remove* function enforcing additional criteria like entry expiration, etc.

Returns

This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get_size* functions of the removed entries).

inline void **clear**()

Clear the cache.

Unconditionally removes all stored entries from the cache.

inline constexpr *statistics_type* const &**get_statistics**() const noexcept

Allow to access the embedded statistics instance.

Returns

This function returns a reference to the statistics instance embedded inside this cache

inline *statistics_type* &**get_statistics**() noexcept

hpx/cache/lru_cache.hpp

Defined in header hpx/cache/lru_cache.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **cache**

template<typename **Key**, typename **Entry**, typename **Statistics** = *statistics*::*no_statistics*>

class **lru_cache**

#include <hpx/cache/lru_cache.hpp> The lru_cache implements the basic functionality needed for a local (non-distributed) LRU cache.

Template Parameters

- **Key** – The type of the keys to use to identify the entries stored in the cache
- **Entry** – The type of the items to be held in the cache.
- **Statistics** – A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type statistics::no_statistics which does not collect any numbers, but provides empty stubs allowing the code to compile.

Public Types

using **key_type** = *Key*

using **entry_type** = *Entry*

using **statistics_type** = *Statistics*

using **entry_pair** = *std*::pair<*key_type*, *entry_type*>

using **storage_type** = *std*::list<*entry_pair*>

using **map_type** = *std*::map<*Key*, typename *storage_type*::iterator>

using **size_type** = *std*::size_t

Public Functions

inline explicit **lru_cache**(*size_type* max_size = 0)

Construct an instance of a *lru_cache*.

Parameters

max_size – [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry's *get_size* function.

lru_cache(*lru_cache* const &other) = default

lru_cache(*lru_cache* &&other) = default

lru_cache &**operator=**(*lru_cache* const &other) = default

lru_cache &**operator=**(*lru_cache* &&other) = default

~lru_cache() = default

inline constexpr *size_type* **size**() const noexcept

Return current size of the cache.

Returns

The current size of this cache instance.

inline constexpr *size_type* **capacity**() const noexcept

Access the maximum size the cache is allowed to grow to.

> **Note**
>
> The unit of this value is usually determined by the unit of the return values of the entry's function *entry::get_size*.

Returns

The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

inline void **reserve**(*size_type* max_size)

Change the maximum size this cache can grow to.

Parameters

max_size – [in] The new maximum size this cache will be allowed to grow to.

inline bool **holds_key**(*key_type* const &key) const

Check whether the cache currently holds an entry identified by the given key.

> **Note**
>
> This function does not call the entry's function *entry::touch*. It just checks if the cache contains an entry corresponding to the given key.

Parameters

`key` – [in] The key for the entry which should be looked up in the cache.

Returns

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **`get_entry`**(*key_type* const &key, *key_type* &realkey, *entry_type* &entry)

Get a specific entry identified by the given key.

> **Note**
>
> The function will "touch" the entry and mark it as recently used if the key was found in the cache.

Parameters

- **`key`** – **[in]** The key for the entry which should be retrieved from the cache.
- **`realkey`** – **[out]** Return the full real key found in the cache
- **`entry`** – **[out]** If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

Returns

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

inline bool **`get_entry`**(*key_type* const &key, *entry_type* const &entry)

Get a specific entry identified by the given key.

> **Note**
>
> The function will "touch" the entry and mark it as recently used if the key was found in the cache.

Parameters

- **`key`** – [in] The key for the entry which should be retrieved from the cache.
- **`entry`** – [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

Returns

This function returns *true* if the cache holds the referenced entry, otherwise it returns *false*.

template<typename **`Entry_`**, typename = *std*::enable_if_t<*std*::is_convertible_v<*std*::decay_t<*Entry_*>, *entry_type*>>>
inline bool **`insert`**(*key_type* const &key, *Entry_* &&entry)

Insert a new entry into this cache.

> **Note**

This function assumes that the entry is not in the cache already. Inserting an already existing entry is considered undefined behavior

Parameters

- **`key`** – [in] The key for the entry which should be added to the cache.
- **`entry`** – [in] The entry which should be added to the cache.

template<typename **`Entry_`**, typename = *std*::enable_if_t<*std*::is_convertible_v<*std*::decay_t<*Entry_*>, *entry_type*>>>
inline void **`update`**(*key_type* const &key, *Entry_* &&entry)

Update an existing element in this cache.

> **Note**
>
> The function will "touch" the entry and mark it as recently used if the key was found in the cache.

> **Note**
>
> The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

Parameters

- **`key`** – [in] The key for the value which should be updated in the cache.
- **`entry`** – [in] The entry which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

template<typename **`F`**, typename **`Entry_`**, *std*::enable_if_t<*std*::is_convertible_v<*std*::decay_t<*Entry_*>, *entry_type*>, int> = 0>
inline bool **`update_if`**(*key_type* const &key, *Entry_* &&entry, *F* &&f)

Update an existing element in this cache.

> **Note**
>
> The function will "touch" the entry and mark it as recently used if the key was found in the cache.

> **Note**
>
> The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

Parameters

- **`key`** – [in] The key for the value which should be updated in the cache.
- **`entry`** – [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- **`f`** – [in] A callable taking two arguments, k and the key found in the cache (in that order). If f returns true, then the update will continue. If f returns false, then the

update will not succeed.

Returns

This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

template<typename **Func**>
inline *size_type* **erase**(*Func* const &ep)

Remove stored entries from the cache for which the supplied function object returns true.

Parameters

ep – [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is *true*.

Returns

This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get_size* functions of the removed entries).

inline *size_type* **erase**()

Remove all stored entries from the cache.

Returns

This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get_size* functions of the removed entries).

inline *size_type* **clear**()

Clear the cache.

Unconditionally removes all stored entries from the cache.

inline constexpr *statistics_type* const &**get_statistics**() const noexcept

Allow to access the embedded statistics instance.

Returns

This function returns a reference to the statistics instance embedded inside this cache

inline *statistics_type* &**get_statistics**() noexcept

Public Static Functions

static inline constexpr void **`got_hit()`** noexcept

The function *got_hit* will be called by a cache instance whenever an entry got touched.

static inline constexpr void **`got_miss()`** noexcept

The function *got_miss* will be called by a cache instance whenever a requested entry has not been found in the cache.

static inline constexpr void **`got_insertion()`** noexcept

The function *got_insertion* will be called by a cache instance whenever a new entry has been inserted.

static inline constexpr void **`got_eviction()`** noexcept

The function *got_eviction* will be called by a cache instance whenever an entry has been removed from the cache because a new inserted entry let the cache grow beyond its capacity.

static inline constexpr void **`clear()`** noexcept

Reset all statistics.

static inline constexpr *std*::int64_t **`get_get_entry_count`**(bool) noexcept

The function *get_get_entry_count* returns the number of invocations of the get_entry() API function of the cache.

static inline constexpr *std*::int64_t **`get_insert_entry_count`**(bool) noexcept

The function *get_insert_entry_count* returns the number of invocations of the insert_entry() API function of the cache.

static inline constexpr *std*::int64_t **`get_update_entry_count`**(bool) noexcept

The function *get_update_entry_count* returns the number of invocations of the update_entry() API function of the cache.

static inline constexpr *std*::int64_t **`get_erase_entry_count`**(bool) noexcept

The function *get_erase_entry_count* returns the number of invocations of the erase() API function of the cache.

static inline constexpr *std*::int64_t **`get_get_entry_time`**(bool) noexcept

The function *get_get_entry_time* returns the overall time spent executing of the get_entry() API function of the cache.

static inline constexpr *std*::int64_t **`get_insert_entry_time`**(bool) noexcept

The function *get_insert_entry_time* returns the overall time spent executing of the insert_entry() API function of the cache.

static inline constexpr *std*::int64_t **`get_update_entry_time`**(bool) noexcept

The function *get_update_entry_time* returns the overall time spent executing of the update_entry() API function of the cache.

static inline constexpr *std*::int64_t **`get_erase_entry_time`**(bool) noexcept

The function *get_erase_entry_time* returns the overall time spent executing of the erase() API function of the cache.

struct **`update_on_exit`**

#include <no_statistics.hpp> Helper class to update timings and counts on function exit.

Public Functions

inline constexpr **`update_on_exit`**(*no_statistics* const&, *method*) noexcept

`~update_on_exit`() = default

`update_on_exit`(*update_on_exit* const&) = delete

`update_on_exit`(*update_on_exit*&&) = delete

update_on_exit &**`operator=`**(*update_on_exit* const&) = delete

update_on_exit &**`operator=`**(*update_on_exit*&&) = delete

hpx/cache/statistics/local_statistics.hpp

Defined in header hpx/cache/statistics/local_statistics.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`util`**

namespace **`cache`**

inline *std*::size_t **`insertions`**(bool const reset) noexcept

inline *std*::size_t **`evictions`**(bool const reset) noexcept

inline void **`got_hit`**() noexcept

The function *got_hit* will be called by a cache instance whenever an entry got touched.

inline void **got_miss**() noexcept

The function *got_miss* will be called by a cache instance whenever a requested entry has not been found in the cache.

inline void **got_insertion**() noexcept

The function *got_insertion* will be called by a cache instance whenever a new entry has been inserted.

inline void **got_eviction**() noexcept

The function *got_eviction* will be called by a cache instance whenever an entry has been removed from the cache because a new inserted entry let the cache grow beyond its capacity.

inline void **clear**() noexcept

Reset all statistics.

Private Members

std::size_t **hits_** = 0

std::size_t **misses_** = 0

std::size_t **insertions_** = 0

std::size_t **evictions_** = 0

Private Static Functions

static inline *std*::size_t **get_and_reset**(*std*::size_t &value, bool const reset) noexcept

hpx/cache/entries/entry.hpp

Defined in header hpx/cache/entries/entry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

template<typename **Value**>

class **`entry`**

#include <hpx/cache/entries/entry.hpp>

Template Parameters

`Value` – The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Subclassed by *hpx::util::cache::entries::fifo_entry< Value >*, *hpx::util::cache::entries::lfu_entry< Value >*, *hpx::util::cache::entries::lru_entry< Value >*, *hpx::util::cache::entries::size_entry< Value >*

Public Types

using **`value_type`** = *Value*

The type of value stored in this cache entry.

Public Functions

`entry``()` = default

Any cache entry has to be default constructible.

inline explicit **`entry`**`(`*value_type* const &val`)` noexcept(*std*::is_nothrow_copy_constructible_v<*value_type*>)

Construct a new instance of a cache entry holding the given value.

inline explicit **`entry`**`(`*value_type* &&val`)` noexcept

Construct a new instance of a cache entry holding the given value.

inline *value_type* &**`get`**`()` noexcept

Get a reference to the stored data value.

> **Note**
>
> This function is part of the CacheEntry concept

inline constexpr *value_type* const &**`get`**`()` const noexcept

Returns a const reference to the stored value.

> **Note**
>
> This function is part of the CacheEntry concept.

Public Static Functions

static inline constexpr bool **`touch`**`()` noexcept

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

> **Note**
>
> It is possible to change the entry in a way influencing the sort criteria mandated by the UpdatePolicy. In this case the function should return *true* to indicate this to the cache, forcing to reorder the cache entries.

> **Note**
>
> This function is part of the CacheEntry concept

Returns

This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

static inline constexpr bool **`insert`**`()` noexcept

The function *insert* is called by a cache whenever it is about to be inserted into the cache.

> **Note**
>
> This function is part of the CacheEntry concept

Returns

This function should return *true* if the entry should be added to the cache, otherwise it should return *false*.

static inline constexpr bool **`remove`**`()` noexcept

The function *remove* is called by a cache holding this instance whenever it is about to be removed from the cache.

> **Note**
>
> This function is part of the CacheEntry concept

Returns

The return value can be used to avoid removing this instance from the cache. If the value is *true* it is ok to remove the entry, otherwise it will stay in the cache.

static inline constexpr *std*::size_t **`get_size`**`()` noexcept

Return the 'size' of this entry. By default, the size of each entry is just one (1), which is sensible if the cache has a limit (capacity) measured in number of entries.

Private Members

value_type **`value_`**

Friends

friend auto **`operator<=>`**`(`*entry* const&, *entry* const&`)` = default

Forwarding operator<=> allowing to compare entries instead of the values.

hpx/cache/entries/lru_entry.hpp

Defined in header hpx/cache/entries/lru_entry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`util`**

namespace **`cache`**

namespace **`entries`**

template<typename **`Value`**>

class **`lru_entry`** : public *hpx*::*util*::*cache*::*entries*::*entry*<*Value*>

#include <hpx/cache/entries/lru_entry.hpp> The lru_entry type can be used to store arbitrary values in a cache. Using this type as the cache's entry type makes sure that the least recently used entries are discarded from the cache first.

Note

The lru_entry conforms to the CacheEntry concept.

Note

This type can be used to model a 'most recently used' cache policy if it is used with a std::greater as the caches' UpdatePolicy (instead of the default std::less).

Template Parameters

`Value` – The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Public Functions

inline **lru_entry**()

Any cache entry has to be default constructible.

inline explicit **lru_entry**(*Value* const &val) noexcept(*std*::is_nothrow_constructible_v<*base_type*, *Value* const&>)

Construct a new instance of a cache entry holding the given value.

inline explicit **lru_entry**(*Value* &&val) noexcept

Construct a new instance of a cache entry holding the given value.

inline bool **touch**()

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LRU entry we store the time of the last access which will be used to compare the age of an entry during the invocation of the *operator<()*.

Returns

This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

inline constexpr *time_point* const &**get_access_time**() const noexcept

Returns the last access time of the entry.

Private Types

using **base_type** = *entry*<*Value*>

using **time_point** = *std*::chrono::steady_clock::time_point

Private Members

time_point **access_time_**

Friends

inline friend auto **operator<**(*lru_entry* const &lhs, *lru_entry* const &rhs)

Compare the 'age' of two entries. An entry is 'older' than another entry if it has been accessed less recently (LRU).

inline friend auto **operator>**(*lru_entry* const &lhs, *lru_entry* const &rhs)

inline friend auto **operator<=**(*lru_entry* const &lhs, *lru_entry* const &rhs)

inline friend auto **operator>=**(*lru_entry* const &lhs, *lru_entry* const &rhs)

inline friend auto **operator==**(*lru_entry* const &lhs, *lru_entry* const &rhs)

inline friend auto **operator!=**(*lru_entry* const &lhs, *lru_entry* const &rhs)

hpx/cache/entries/lfu_entry.hpp

Defined in header hpx/cache/entries/lfu_entry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`util`**

namespace **`cache`**

namespace **`entries`**

template<typename **`Value`**>

class **`lfu_entry`** : public *hpx*::*util*::*cache*::*entries*::*entry*<*Value*>

#include <hpx/cache/entries/lfu_entry.hpp> The lfu_entry type can be used to store arbitrary values in a cache. Using this type as the cache's entry type makes sure that the least frequently used entries are discarded from the cache first.

> **Note**
>
> The lfu_entry conforms to the CacheEntry concept.

> **Note**
>
> This type can be used to model a 'most frequently used' cache policy if it is used with a std::greater as the caches' UpdatePolicy (instead of the default std::less).

Template Parameters

`Value` – The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Public Functions

`lfu_entry`() = default

Any cache entry has to be default constructible.

inline explicit **`lfu_entry`**(*Value* const &val) noexcept(*std*::is_nothrow_constructible_v<*base_type*, *Value* const&>)

Construct a new instance of a cache entry holding the given value.

inline explicit **`lfu_entry`**(*Value* &&val) noexcept

Construct a new instance of a cache entry holding the given value.

inline bool **`touch`**`()` noexcept

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LFU entry we store the reference count tracking the number of times this entry has been requested. This which will be used to compare the age of an entry during the invocation of the *operator<()*.

Returns

This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache's UpdatePolicy

inline constexpr unsigned long const &**`get_access_count`**`()` const noexcept

Private Types

using **`base_type`** = *entry*<*Value*>

Private Members

unsigned long **`ref_count_`** = 0

Friends

inline friend auto **`operator<`**`(`*lfu_entry* const &lhs, *lfu_entry* const &rhs)

Compare the 'age' of two entries. An entry is 'older' than another entry if it has been accessed less frequently (LFU).

hpx/cache/entries/size_entry.hpp

Defined in header hpx/cache/entries/size_entry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`util`**

namespace **`cache`**

namespace **`entries`**

template<typename **`Value`**>

class **`size_entry`** : public *hpx*::*util*::*cache*::*entries*::*entry*<*Value*>

#include <hpx/cache/entries/size_entry.hpp> The size_entry type can be used to store values in a cache which have a size associated (such as files, etc.). Using this type as the cache's entry type makes sure that the entries with the biggest size are discarded from the cache first.

> **Note**
>
> The size_entry conforms to the CacheEntry concept.

> **Note**
>
> This type can be used to model a 'discard smallest first' cache policy if it is used with a std::greater as the caches' UpdatePolicy (instead of the default std::less).

Template Parameters

`Value` – The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Public Functions

`size_entry`() = default

Any cache entry has to be default constructible.

inline explicit **`size_entry`**(*Value* const &val, *std*::size_t size = 0) noexcept(*std*::is_nothrow_constructible_v<*base_type*, *Value* const&>)

Construct a new instance of a cache entry holding the given value.

inline explicit **`size_entry`**(*Value* &&val, *std*::size_t size = 0) noexcept

Construct a new instance of a cache entry holding the given value.

inline constexpr *std*::size_t **`get_size`**() const noexcept

Return the 'size' of this entry.

Private Types

using **`base_type`** = *entry*<*Value*>

Private Members

std::size_t **size_** = 0

Friends

inline friend auto **operator<**(*size_entry* const &lhs, *size_entry* const &rhs) noexcept

Compare the 'age' of two entries. An entry is 'older' than another entry if it has a bigger size.

hpx/cache/entries/fifo_entry.hpp

Defined in header hpx/cache/entries/fifo_entry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **cache**

namespace **entries**

template<typename **Value**>

class **fifo_entry** : public *hpx*::*util*::*cache*::*entries*::*entry*<*Value*>

#include <hpx/cache/entries/fifo_entry.hpp> The fifo_entry type can be used to store arbitrary values in a cache. Using this type as the cache's entry type makes sure that the least recently inserted entries are discarded from the cache first.

Note

The fifo_entry conforms to the CacheEntry concept.

Note

This type can be used to model a 'last in first out' cache policy if it is used with a std::greater as the caches' UpdatePolicy (instead of the default std::less).

Template Parameters

Value – The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Public Functions

fifo_entry() = default

Any cache entry has to be default constructible.

inline explicit **fifo_entry**(*Value* const &val) noexcept(*std*::is_nothrow_constructible_v<*base_type*, *Value* const&>)

Construct a new instance of a cache entry holding the given value.

inline explicit **fifo_entry**(*Value* &&val) noexcept

Construct a new instance of a cache entry holding the given value.

inline constexpr bool **insert**()

The function *insert* is called by a cache whenever it is about to be inserted into the cache.

> **Note**
>
> This function is part of the CacheEntry concept

Returns

This function should return *true* if the entry should be added to the cache, otherwise it should return *false*.

inline constexpr *time_point* const &**get_creation_time**() const noexcept

Private Types

using **base_type** = *entry*<*Value*>

checkpoint_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/checkpoint_base/checkpoint_data.hpp

Defined in header hpx/checkpoint_base/checkpoint_data.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

Functions

template<typename **Container**, typename ...**Ts**>
void **save_checkpoint_data**(*Container* &data, *Ts*&&... ts)

save_checkpoint_data

Save_checkpoint_data takes any number of objects which a user may wish to store in the given container.

Template Parameters

- **Container** – Container used to store the check-pointed data.
- **Ts** – Types of variables to checkpoint

Parameters

- **data** – Container instance used to store the checkpoint data
- **ts** – Variable instances to be inserted into the checkpoint.

template<typename ...**Ts**>
std::size_t **prepare_checkpoint_data**(*Ts* const&... ts)

prepare_checkpoint_data

prepare_checkpoint_data takes any number of objects which a user may wish to store in a subsequent save_checkpoint_data operation. The function will return the number of bytes necessary to store the data that will be produced.

Template Parameters

`Ts` – Types of variables to checkpoint

Parameters

`ts` – Variable instances to be inserted into the checkpoint.

template<typename **`Container`**, typename ...**`Ts`**>
void **`restore_checkpoint_data`**(*Container* const &cont, *Ts*&... ts)

restore_checkpoint_data

restore_checkpoint_data takes any number of objects which a user may wish to restore from the given container. The sequence of objects has to correspond to the sequence of objects for the corresponding call to save_checkpoint_data that had used the given container instance.

Template Parameters

- `Container` – Container used to restore the check-pointed data.
- `Ts` – Types of variables to restore

Parameters

- `cont` – Container instance used to restore the checkpoint data
- `ts` – Variable instances to be restored from the container

template<typename **InIter**>
inline void **assign**(*InIter* first, *InIter* last)

inline void **assign**(*std*::initializer_list<*T*> ilist)

inline *allocator_type* **get_allocator**() const noexcept

Returns the allocator associated with the container.

inline *reference* **at**(*size_type* pos)

inline *const_reference* **at**(*size_type* pos) const

inline *reference* **operator[]**(*size_type* pos)

inline *const_reference* **operator[]**(*size_type* pos) const

inline *reference* **front**()

Returns a reference to the first element in the container. Calling front on an empty container is undefined.

inline *const_reference* **front**() const

Returns a reference to the first element in the container. Calling front on an empty container is undefined.

inline *reference* **back**()

Returns a reference to the last element in the container. Calling back on an empty container is undefined.

inline *const_reference* **back**() const

Returns a reference to the last element in the container. Calling back on an empty container is undefined.

inline *pointer* **data**() noexcept

Returns pointer to the underlying array serving as element storage. The pointer is such that range [*data()*; *data()* + size()) is always a valid range, even if the container is empty (*data()* is not dereference-able in that case).

inline *const_pointer* **data**() const noexcept

Returns pointer to the underlying array serving as element storage. The pointer is such that range [*data()*; *data()* + size()) is always a valid range, even if the container is empty (*data()* is not dereference-able in that case).

inline *T* ***device_data**() const noexcept

Returns a raw pointer corresponding to the address of the data allocated on the device.

inline *std*::size_t **size**() const noexcept

inline *std*::size_t **capacity**() const noexcept

inline bool **empty**() const noexcept

Returns: size() == 0.

inline void **resize**(*size_type*)

Effects: If size <= size(), equivalent to calling pop_back() size()

- size times. If size() < size, appends size - size() default-inserted elements to the sequence.

Requires: T shall be MoveInsertable and DefaultInsertable into *this.

Remarks: If an exception is thrown other than by the move constructor of a non-CopyInsertable T there are no effects.

inline void **resize**(*size_type*, *T* const&)

Effects: If size <= size(), equivalent to calling pop_back() size() - size times. If size() < size, appends size - size() copies of val to the sequence.

Requires: T shall be CopyInsertable into *this.

Remarks: If an exception is thrown there are no effects.

inline *iterator* **begin**() noexcept

inline *iterator* **end**() noexcept

inline *const_iterator* **cbegin**() const noexcept

inline *const_iterator* **cend**() const noexcept

inline *const_iterator* **begin**() const noexcept

inline *const_iterator* **end**() const noexcept

inline *reverse_iterator* **rbegin**() noexcept

inline *const_reverse_iterator* **crend**() const noexcept

inline *const_reverse_iterator* **rbegin**() const noexcept

inline *const_reverse_iterator* **rend**() const noexcept inline void **swap**(*vector* &other) noexcept

Effects: Exchanges the contents and capacity() of *this with that of x.

Complexity: Constant time.

inline void **clear**() noexcept

Effects: Erases all elements in the range [begin(),end()). Destroys all elements in ‘a’. Invalidates all references, pointers, and iterators referring to the elements of a and may invalidate the past-the-end iterator.

Post: a.empty() returns true.

Complexity: Linear.

inline void **construct**(*U* *p, *A*&&... args)

template<class **U**>
inline void **destroy**(*U* *const p)

inline void **initialize_pages**(*pointer* p, size_t n) const

Touches every page of the allocation starting at *p* so that each page is physically bound to the NUMA domain assigned to it by *binding_helper_*. One first-touch task per NUMA domain is dispatched and the call blocks until all of them complete.

Parameters

- **p** – pointer to the start of the allocation to initialize.
- **n** – number of elements to initialize.

Pre

Must be called from an HPX thread. init_mutex serializes concurrent calls to this function and is intentionally held across hpx::wait_all() below, which is a suspension point that may resume the calling HPX thread on a different OS worker thread. hpx::mutex (unlike std::mutex) supports this safely, and ignore_while_checking silences the HPX lock-checking layer's warning about a lock spanning a suspension point.

inline *std*::string **`display_binding`**(*pointer* p, *numa_binding_helper_ptr* helper)

Builds a human-readable, page-by-page description of how the allocation starting at *p* is bound across NUMA domains, suitable for debug output. init_mutex is held only for the duration of this synchronous call; unlike *initialize_pages()*, no suspension point is crossed while it is held.

Parameters

- **`p`** – pointer to the start of the allocation to describe.
- **`helper`** – binding helper describing the array layout used to compute per-page offsets.

Returns

a formatted string describing the domain binding of each page in the allocation.

hpx/compute_local/host/block_fork_join_executor.hpp

Defined in header hpx/compute_local/host/block_fork_join_executor.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

class **block_fork_join_executor**

#include <block_fork_join_executor.hpp> An executor with fork-join (blocking) semantics.

The *block_fork_join_executor* creates on construction a set of worker threads that are kept alive for the duration of the executor. Copying the executor has reference semantics, i.e. copies of a fork_join_executor hold a reference to the worker threads of the original instance. Scheduling work through the executor concurrently from different threads is undefined behaviour.

The executor keeps a set of worker threads alive for the lifetime of the executor, meaning other work will not be executed while the executor is busy or waiting for work. The executor has a customizable delay after which it will yield to other work. Since starting and resuming the worker threads is a slow operation the executor should be reused whenever possible for multiple adjacent parallel algorithms or invocations of bulk_(a)sync_execute.

This behaviour is similar to the plain *fork_join_executor* except that the *block_fork_join_executor* creates a hierarchy of fork_join_executors, one for each target used to initialize it.

Public Functions

inline explicit **block_fork_join_executor**(*threads*::*thread_priority* const priority = *threads*::*thread_priority*::*bound*, *threads*::*thread_stacksize* const stacksize = *threads*::*thread_stacksize*::*small_*, fork_join_executor::loop_schedule const schedule = fork_join_executor::loop_schedule::static_, *std*::chrono::nanoseconds const yield_delay = *std*::chrono::milliseconds(1))

Construct a *block_fork_join_executor*.

> **Note**
>
> This constructor will create one fork_join_executor for each numa domain

Parameters

- **priority** – The priority of the worker threads.
- **stacksize** – The stacksize of the worker threads. Must not be nostack.
- **schedule** – The loop schedule of the parallel regions.
- **yield_delay** – The time after which the executor yields to other work if it has not received any new work for execution.

inline explicit **block_fork_join_executor**(*std*::vector<*compute*::*host*::target> const &targets, *threads*::*thread_priority* const priority = *threads*::*thread_priority*::*bound*, *threads*::*thread_stacksize* const stacksize = *threads*::*thread_stacksize*::*small_*, fork_join_executor::loop_schedule const schedule = fork_join_executor::loop_schedule::static_, *std*::chrono::nanoseconds const yield_delay = *std*::chrono::milliseconds(1))

Construct a *block_fork_join_executor*.

Note

This constructor will create one fork_join_executor for each given target

Parameters

- **`targets`** – The list of targets to use for thread placement
- **`priority`** – The priority of the worker threads.
- **`stacksize`** – The stacksize of the worker threads. Must not be nostack.
- **`schedule`** – The loop schedule of the parallel regions.
- **`yield_delay`** – The time after which the executor yields to other work if it has not received any new work for execution.

config

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/config.hpp

Defined in header hpx/config.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_INITIAL_IP_PORT

This is the default ip/port number used by the parcel subsystem.

HPX_CONNECTING_IP_PORT

HPX_INITIAL_IP_ADDRESS

HPX_RUNTIME_INSTANCE_LIMIT

This defines the maximum number of possible runtime instances in one executable

HPX_PARCEL_BOOTSTRAP

This defines the type of the parcelport to be used during application bootstrap. This value can be changed at runtime by the configuration parameter:

hpx.parcel.bootstrap = …

(or by setting the corresponding environment variable HPX_PARCEL_BOOTSTRAP).

HPX_PARCEL_MAX_CONNECTIONS

This defines the number of outgoing (parcel-) connections kept alive (to all other localities). This value can be changed at runtime by setting the configuration parameter:

hpx.parcel.max_connections = …

(or by setting the corresponding environment variable HPX_PARCEL_MAX_CONNECTIONS).

`HPX_PARCEL_IPC_DATA_BUFFER_CACHE_SIZE`

This defines the number of outgoing ipc (parcel-) connections kept alive (to each of the other localities on the same node). This value can be changed at runtime by setting the configuration parameter:

hpx.parcel.ipc.data_buffer_cache_size = …

(or by setting the corresponding environment variable HPX_PARCEL_IPC_DATA_BUFFER_CACHE_SIZE).

`HPX_PARCEL_MPI_MAX_REQUESTS`

This defines the number of MPI requests in flight This value can be changed at runtime by setting the configuration parameter:

hpx.parcel.mpi.max_requests = …

(or by setting the corresponding environment variable HPX_PARCEL_MPI_MAX_REQUESTS).

`HPX_HAVE_PARCELPORT_MPI_BACKGROUND_THREADS`

This defines the number of cores that perform background work for the MPI parcelport This value can be changed at runtime by setting the configuration parameter:

hpx.parcel.mpi.background_threads = …

(or by setting the corresponding environment variable HPX_HAVE_PARCELPORT_MPI_BACKGROUND_THREADS).

`HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY`

This defines the number of outgoing (parcel-) connections kept alive (to each of the other localities). This value can be changed at runtime by setting the configuration parameter:

hpx.parcel.max_connections_per_locality = …

(or by setting the corresponding environment variable HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY).

`HPX_PARCEL_MAX_MESSAGE_SIZE`

This defines the maximally allowed message size for messages transferred between localities. This value can be changed at runtime by setting the configuration parameter:

hpx.parcel.max_message_size = …

(or by setting the corresponding environment variable HPX_PARCEL_MAX_MESSAGE_SIZE).

`HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE`

This defines the maximally allowed outbound message size for coalescing messages transferred between localities. This value can be changed at runtime by setting the configuration parameter:

hpx.parcel.max_outbound_message_size = …

(or by setting the corresponding environment variable HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE).

`HPX_PARCEL_SERIALIZATION_OVERHEAD`

`HPX_AGAS_LOCAL_CACHE_SIZE`

This defines the number of AGAS address translations kept in the local cache. This is just the initial size which may be adjusted depending on the load of the system (not implemented yet), etc. It must be a minimum of 3 for AGAS v3 bootstrapping.

This value can be changes at runtime by setting the configuration parameter:

hpx.agas.local_cache_size = …

(or by setting the corresponding environment variable HPX_AGAS_LOCAL_CACHE_SIZE)

`HPX_AGAS_RPC_TIMEOUT`

This defines the default AGAS RPC timeout in milliseconds.

This value can be changed at runtime by setting the configuration parameter:

```
hpx.agas.rpc_timeout = val
```

(or by setting the corresponding environment variable HPX_AGAS_RPC_TIMEOUT)

`HPX_INITIAL_AGAS_MAX_PENDING_REFCNT_REQUESTS`

`HPX_GLOBALCREDIT_INITIAL`

This defines the initial global reference count associated with any created object.

`HPX_NUM_IO_POOL_SIZE`

This defines the default number of OS-threads created for the different internal thread pools

`HPX_NUM_PARCEL_POOL_SIZE`

`HPX_NUM_TIMER_POOL_SIZE`

`HPX_SPINLOCK_DEADLOCK_DETECTION_LIMIT`

By default, enable minimal thread deadlock detection in debug builds only.

`HPX_HAVE_THREAD_BACKTRACE_DEPTH`

By default we capture only 20 levels of stack back trace on suspension.

By default we do not maintain stack back-traces on suspension. This is a pure debugging aid to be able to see in the debugger where a suspended thread got stuck.

`HPX_MAX_NETWORK_RETRIES`

`HPX_NETWORK_RETRIES_SLEEP`

`HPX_INI_PATH_DELIMITER`

`HPX_PATH_DELIMITERS`

`HPX_SHARED_LIB_EXTENSION`

`HPX_EXECUTABLE_EXTENSION`

Enums

enum class **thread_schedule_state** : *std*::int8_t

The *thread_schedule_state* enumerator encodes the current state of a *thread* instance

Task Lifecycle State Transitions:

```
stateDiagram-v2
    %% Creation Phase
    [*] --> Staged : task_staged
    [*] --> Pending : task_created
    [*] --> Suspended : task_created
    Staged --> Pending : task_created
```

(continues on next page)

(continued from previous page)

```
    %% Execution Loop
    Pending --> Active : task_executing
    Active --> Pending : task_yielded

    %% Sleep / Wake Cycle
    Active --> Suspended : task_suspended
    Suspended --> Pending : task_resumed

    %% Termination Paths
    Active --> Terminated : task_completed
    Active --> Deleted : task_completed (Inline fast-path)
    Pending --> Terminated : task_completed (Aborted)
    Suspended --> Terminated : task_completed (Aborted)

    %% Cleanup (Destruction / Recycling)
    Terminated --> Deleted : task_deleted
    Deleted --> [*]
```

Values:

enumerator **`unknown`**

enumerator **`active`**

thread is currently active (running, has resources)

enumerator **`pending`**

thread is pending (ready to run, but no hardware resource available)

enumerator **`suspended`**

thread has been suspended (waiting for synchronization event, but still known and under control of the thread-manager)

enumerator **`depleted`**

thread has been depleted (deeply suspended, it is not known to the thread-manager)

enumerator **`terminated`**

thread has been stopped and may be garbage collected

enumerator **`staged`**

this is not a real thread state, but allows to reference staged task descriptions, which eventually will be converted into thread objects

enumerator **`pending_do_not_schedule`**

this is not a real thread state, but allows to create a thread in pending state without scheduling it (internal, do not use)

enumerator **`pending_boost`**

this is not a real thread state, but allows to suspend a thread in pending state without high priority rescheduling enumerator **`deleted`**

thread has been stopped and was deleted

enum class **`thread_priority`** : *std*::int8_t

This enumeration lists all possible thread-priorities for HPX threads.

Values:

enumerator **`unknown`**

enumerator **`default_`**

Will assign the priority of the task to the default (normal) priority.

enumerator **`low`**

Task goes onto a special low priority queue and will not be executed until all high/normal priority tasks are done, even if they are added after the low priority task.

enumerator **`normal`**

Task will be executed when it is taken from the normal priority queue, this is usually a first in-first-out ordering of tasks (depending on scheduler choice). This is the default priority.

enumerator **`high_recursive`**

The task is a high priority task and any child tasks spawned by this task will be made high priority as well - unless they are specifically flagged as non default priority.

enumerator **`boost`**

Same as *thread_priority_high* except that the thread will fall back to *thread_priority_normal* if resumed after being suspended.

enumerator **`high`**

Task goes onto a special high priority queue and will be executed before normal/low priority tasks are taken (some schedulers modify the behavior slightly and the documentation for those should be consulted).

enumerator **`bound`**

Task goes onto a special high priority queue and will never be stolen by another thread after initial assignment. This should be used for thread placement tasks such as OpenMP type for loops. Schedulers that ignore thread priorities (e.g. the local queue scheduler selected with *hpx:queuing=local*) do not provide this guarantee: for those, this value only affects the initial placement, and the thread may be stolen by, or resumed on, another worker thread. A bound thread that has not run yet and is scheduled on a worker thread after that worker has left its scheduling loop during shutdown is run by the worker that takes over the remaining work.

enumerator **`initially_bound`**

Task initially goes onto a special high priority queue and will never be stolen by another thread after initial assignment. If the thread is rescheduled later, it will use normal priority. Schedulers that ignore thread priorities (e.g. the local queue scheduler selected with *hpx:queuing=local*) do not provide this guarantee: for those, this value only affects the initial placement.

enum class **`thread_restart_state`** : *std*::int8_t

The *thread_restart_state* enumerator encodes the reason why a thread is being restarted

Values:

enumerator **`unknown`**

enumerator **`signaled`**

The thread has been signaled.

enumerator **`timeout`**

The thread has been reactivated after a timeout.

enumerator **`terminate`**

The thread needs to be terminated.

enumerator **`abort`**

The thread needs to be aborted.

enum class **`thread_stacksize`** : *std*::int8_t

A *thread_stacksize* references any of the possible stack-sizes for HPX threads.

Values:

enumerator **`unknown`**

enumerator **`small_`**

use small stack size (the underscore is to work around ‘small’ being defined to char on Windows)

enumerator **`medium`**

use medium sized stack size

enumerator **`large`**

use large stack size

enumerator **`huge`**

use very large stack size

enumerator **`nostack`**

this thread does not suspend (does not need a stack)

enumerator **`current`**

use size of current thread’s stack

enumerator **`default_`**

use default stack size

enumerator **`minimal`**

use minimally stack size

enumerator **`maximal`**

use maximally stack size

enum class **`thread_schedule_hint_mode`** : *std*::int8_t

The type of hint given when creating new tasks.

Values:

enumerator **`none`**

A hint that leaves the choice of scheduling entirely up to the scheduler.

enumerator **`thread`**

A hint that tells the scheduler to prefer scheduling a task on the local thread number associated with this hint. Local thread numbers are indexed from zero. It is up to the scheduler to decide how to interpret thread numbers that are larger than the number of threads available to the scheduler. Typically, thread numbers will wrap around when too large.

enumerator **`numa`**

A hint that tells the scheduler to prefer scheduling a task on the NUMA domain associated with this hint. NUMA domains are indexed from zero. It is up to the scheduler to decide how to interpret NUMA domain indices that are larger than the number of available NUMA domains to the scheduler. Typically, indices will wrap around when too large.

enum class **`thread_placement_hint`** : *std*::int8_t

The type of hint given to the scheduler related to thread placement

The type of hint given to the scheduler related running a thread as a child directly in the context of the parent thread

Values:

enumerator **`none`**

No hint is specified. The implementation is free to chose what placement methods to use.

enumerator **`depth_first`**

A hint that tells the scheduler to prefer spreading thread placement on a depth-first basis (i.e. consecutively scheduled threads are placed on the same core).

enumerator **`breadth_first`**

A hint that tells the scheduler to prefer spreading thread placement on a breadth-first basis (i.e. consecutively scheduled threads are placed on the neighboring cores).

enumerator **`depth_first_reverse`**

A hint that tells the scheduler to prefer spreading thread placement on a depth-first basis (i.e. consecutively scheduled threads are placed on the same core). Threads are being scheduled in reverse order.

enumerator **`breadth_first_reverse`**

A hint that tells the scheduler to prefer spreading thread placement on a breadth-first basis (i.e. consecutively scheduled threads are placed on the neighboring cores). Threads are being scheduled in reverse order.

enum class **`thread_sharing_hint`** : *std*::int8_t

The type of hint given to the scheduler related to whether it is ok to share the invoked function object between threads

Values:

enumerator **`none`**

No hint is specified. The implementation is free to chose what sharing methods to use.

enumerator **`do_not_share_function`**

A hint that tells the scheduler to avoid sharing the given function (object) between threads.

enumerator **`do_not_combine_tasks`**

A hint that tells the scheduler to avoid combining tasks on the same thread. This is important for tasks that may synchronize between each other, which could lead to deadlocks if those tasks are combined running by the same thread.

enum class **`thread_execution_hint`** : *std*::int8_t

Values:

enumerator **`none`**

No hint is specified. Always run the thread in its own execution environment.

enumerator **`run_as_child`**

Attempt to run the thread in the execution context of the parent thread.

Functions

std::ostream &**`operator<<`**`(`*std*::ostream &os, *thread_schedule_state* t`)`

char const ***`get_thread_state_name`**`(`*thread_schedule_state* state`)` noexcept

Returns the name of the given state.

Get the readable string representing the name of the given thread_state constant.

Parameters

`state` – this represents the thread state.

std::ostream &**`operator<<`**`(`*std*::ostream &os, *thread_priority* t`)`

char const ***`get_thread_priority_name`**`(`*thread_priority* priority`)` noexcept

Return the thread priority name.

Get the readable string representing the name of the given thread_priority constant.

Parameters

`priority` – this represents the thread priority.

std::ostream &**operator<<**(*std*::ostream &os, *thread_restart_state* t)

char const ***get_thread_state_ex_name**(*thread_restart_state* state) noexcept

Get the readable string representing the name of the given thread_restart_state constant.

char const ***get_thread_state_name**(thread_state state) noexcept

Get the readable string representing the name of the given thread_state constant.

std::ostream &**operator<<**(*std*::ostream &os, *thread_stacksize* t)

char const ***get_stack_size_enum_name**(*thread_stacksize* size) noexcept

Returns the stack size name.

Get the readable string representing the given stack size constant.

Parameters

size – this represents the stack size

constexpr bool **do_not_share_function**(*thread_sharing_hint* hint) noexcept

constexpr bool **do_not_combine_tasks**(*thread_sharing_hint* hint) noexcept

constexpr *thread_sharing_hint* **operator|**(*thread_sharing_hint* lhs, *thread_sharing_hint* rhs) noexcept

constexpr bool **run_as_child**(*thread_execution_hint* hint) noexcept

Variables

constexpr *thread_execution_hint* **default_runs_as_child_hint** = *thread_execution_hint*::*none*

Default value to use for runs-as-child mode (if *true*, then futures will attempt to execute associated threads directly if they have not started running).

struct **thread_schedule_hint**

#include <thread_enums.hpp> A hint given to a scheduler to guide where a task should be scheduled.

A scheduler is free to ignore the hint, or modify the hint to suit the resources available to the scheduler.

Public Functions

inline constexpr **thread_schedule_hint**() noexcept

Construct a default hint with mode *thread_schedule_hint_mode::none*.

inline explicit constexpr **thread_schedule_hint**(*std*::int16_t const thread_hint, *thread_placement_hint* placement = *thread_placement_hint*::*none*, *thread_execution_hint* runs_as_child = *default_runs_as_child_hint*, *thread_sharing_hint* sharing = *thread_sharing_hint*::*none*, *threads*::*task_size* size = *threads*::*task_size*::*unknown*) noexcept

Construct a hint with mode *thread_schedule_hint_mode::thread* and the given hint as the local thread number.

inline constexpr **thread_schedule_hint**(*thread_schedule_hint_mode* const mode, *std*::int16_t const hint, *thread_placement_hint* placement = *thread_placement_hint*::*none*, *thread_execution_hint* runs_as_child = *default_runs_as_child_hint*, *thread_sharing_hint* sharing = *thread_sharing_hint*::*none*, *threads*::*task_size* size = *threads*::*task_size*::*unknown*) noexcept

Construct a hint with the given mode and hint. The numerical hint is unused when the mode is *thread_schedule_hint_mode::none*.

inline explicit constexpr **thread_schedule_hint**(*thread_placement_hint* placement) noexcept

Construct a hint with the given placement hint.

inline explicit constexpr **thread_schedule_hint**(*thread_execution_hint* runs_as_child) noexcept

Construct a hint with the given execution hint.

inline explicit constexpr **thread_schedule_hint**(*thread_sharing_hint* sharing) noexcept

Construct a hint with the given sharing hint.

inline explicit constexpr **thread_schedule_hint**(*threads*::*task_size* size) noexcept

Construct a hint with the given task size.

inline constexpr *thread_schedule_hint_mode* **mode**() const noexcept

inline constexpr void **mode**(*thread_schedule_hint_mode* bits) noexcept

inline constexpr *threads*::*task_size* **task_size**() const noexcept

inline constexpr void **task_size**(*threads*::*task_size* bits) noexcept

inline constexpr *thread_placement_hint* **placement_mode**() const noexcept

inline constexpr void **placement_mode**(*thread_placement_hint* bits) noexcept

inline constexpr *thread_sharing_hint* **sharing_mode**() const noexcept

inline constexpr void **sharing_mode**(*thread_sharing_hint* bits) noexcept

inline constexpr *thread_execution_hint* **runs_as_child_mode**() const noexcept

inline constexpr void **runs_as_child_mode**(*thread_execution_hint* bits) noexcept

inline constexpr void **schedule_hint**(*std*::int16_t core) noexcept

Public Members

std::int16_t **hint** = -1

The hint associated with the mode. The interpretation of this hint depends on the given mode.

std::uint8_t **mode_bits**

The mode of the scheduling hint (thread_schedule_hint_mode needs only 2 bits).

std::uint8_t **task_size_bits**

The expected run time of the task (task_size).

std::uint8_t **placement_mode_bits**

The mode of the desired thread placement.

std::uint8_t **sharing_mode_bits**

The mode of the desired sharing hint.

std::uint8_t **runs_as_child_mode_bits**

The thread will run as a child directly in the context of the current thread

datastructures

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::ignore

Defined in header hpx/tuple.hpp[846].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::tie*
- *hpx::forward_as_tuple*
- *hpx::tuple_cat*
- *hpx::get*

constexpr *hpx*::detail::ignore_type *hpx*::**ignore** = {}

An object of unspecified type such that any value can be assigned to it with no effect. Intended for use with *hpx::tie* when unpacking a *hpx::tuple*, as a placeholder for the arguments that are not used. While the behavior of *hpx::ignore* outside of *hpx::tie* is not formally specified, some code guides recommend using *hpx::ignore* to avoid warnings from unused return values of [[nodiscard]] functions.

- *hpx::tuple_cat*
- *hpx::get*

template<typename ...**Ts**>

class **tuple**

Class template *hpx::tuple* is a fixed-size collection of heterogeneous values. It is a generalization of *hpx::pair*. If *std::is_trivially_destructible<Ti>::value* is true for every *Ti* in *Ts*, the destructor of tuple is trivial.

Param Ts...
the types of the elements that the tuple stores.

hpx::tuple_size

Defined in header hpx/tuple.hpp[848].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **`tuple_size`**

Provides access to the number of elements in a tuple-like type as a compile-time constant expression.

The primary template is not defined. An explicit (full) or partial specialization is required to make a type tuple-like. The Enable parameter allows constraining partial specializations via SFINAE (mirroring *hpx::tuple_element*).

hpx::tuple_element

Defined in header hpx/tuple.hpp[849].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::ignore*
- *hpx::tuple*
- *hpx::tuple_size*
- *hpx::make_tuple*

- *hpx::forward_as_tuple*
- *hpx::tuple_cat*
- *hpx::get*

template<*std*::size_t **`I`**, typename **`T`**, typename **`Enable`** = void>

struct **`tuple_element`**

Provides compile-time indexed access to the types of the elements of a tuple-like type.

The primary template is not defined. An explicit (full) or partial specialization is required to make a type tuple-like.

hpx::make_tuple

Defined in header hpx/tuple.hpp[850].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

- *hpx::make_tuple*
- *hpx::forward_as_tuple*
- *hpx::tuple_cat*
- *hpx::get*

template<typename ...**Ts**>
constexpr *tuple*<*Ts*&...> `hpx::tie`(*Ts*&... ts)

Creates a tuple of lvalue references to its arguments or instances of *hpx::ignore*.

Parameters

`ts` – zero or more lvalue arguments to construct the tuple from.

Returns

hpx::tuple object containing lvalue references.

hpx::forward_as_tuple

Defined in header hpx/tuple.hpp[852].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::ignore*
- *hpx::tuple*

[852] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/tuple.hpp

- *hpx::get*

template<typename ...**Ts**>
constexpr *tuple*<*Ts*&&...> *hpx*::**forward_as_tuple**(*Ts*&&... ts)

Constructs a tuple of references to the arguments in args suitable for forwarding as an argument to a function. The tuple has rvalue reference data members when rvalues are used as arguments, and otherwise has lvalue reference data members.

Parameters

`ts` – zero or more arguments to construct the tuple from

Returns

hpx::tuple object created as if by

```
hpx::tuple<Ts&&...>(HPX_FORWARD(Ts, ts)...)
```

hpx::tuple_cat

Defined in header hpx/tuple.hpp[853].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::ignore*
- *hpx::tuple*
- *hpx::tuple_size*
- *hpx::tuple_element*
- *hpx::make_tuple*
- *hpx::tie*
- *hpx::forward_as_tuple*
- *hpx::get*

template<typename ...**Tuples**>
constexpr auto *hpx*::**tuple_cat**(*Tuples*&&... tuples)

Constructs a tuple that is a concatenation of all tuples in `tuples`. The behavior is undefined if any type in `std::decay_t<Tuples>...` is not a specialization of *`hpx::tuple`*. However, an implementation may choose to support types (such as `std::array` and `std::pair`) that follow the tuple-like protocol.

Parameters

`tuples` – - zero or more tuples to concatenate

Returns

hpx::tuple object composed of all elements of all argument tuples constructed from *`hpx::get<Is>`*(HPX_FORWARD(UTuple,t) for each individual element.

---

hpx::any

Defined in header hpx/any.hpp[860].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::make_any*

using *hpx*::**any** = *util*::basic_any<*serialization*::input_archive, *serialization*::output_archive, char, *std*::true_type>

hpx::make_any

Defined in header hpx/any.hpp[861].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::any*

template<typename **T**, typename **Char**>
util::basic_any<*serialization*::input_archive, *serialization*::output_archive, *Char*> *hpx*::**make_any**(*T* &&t)

Constructs an any object containing an object of type *T*, passing the provided arguments to T's constructor. Equivalent to:

```
return std::any(std::in_place_type<T>, std::forward<Args>(args)...);
```

debugging

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

hpx/errors/define_error_info.hpp

Defined in header hpx/errors/define_error_info.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::exception

Defined in header hpx/exception.hpp[862].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **exception** : public *std*::system_error

A *hpx::exception* is the main exception type used by HPX to report errors.

The *hpx::exception* type is the main exception type used by HPX to report errors. Any exceptions thrown by functions in the HPX library are either of this type or of a type derived from it. This implies that it is always safe to use this type only in catch statements guarding HPX library calls.

Subclassed by hpx::bad_alloc_exception, hpx::cuda::experimental::cuda_exception, *hpx::exception_list*, *hpx::experimental::task_canceled_exception*, hpx::mpi::experimental::mpi_exception

---

[862] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/exception.hpp

hpx/errors/exception_list.hpp

Defined in header hpx/errors/exception_list.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

class **exception_list** : public *hpx*::*exception*

#include <exception_list.hpp> The class *exception_list* is a container of exception_ptr objects parallel algorithms may use to communicate uncaught exceptions encountered during parallel execution to the caller of the algorithm

The type exception_list::const_iterator fulfills the requirements of a forward iterator.

Public Types

using **iterator** = exception_list_type::const_iterator

bidirectional iterator

Public Functions

inline *std*::size_t **size**() const noexcept

The number of exception_ptr objects contained within the *exception_list*.

> **Note**
>
> Complexity: Constant time.

inline exception_list_type::const_iterator **begin**() const noexcept

An iterator referring to the first exception_ptr object contained within the *exception_list*.

inline exception_list_type::const_iterator **end**() const noexcept

An iterator which is the past-the-end value for the *exception_list*.

hpx::error_code

Defined in header hpx/system_error.hpp[863].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **error_code** : public *std*::error_code

A *hpx::error_code* represents an arbitrary error condition.

The class *hpx::error_code* describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

---

[863] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/system_error.hpp

Note

Class *hpx::error_code* is an adjunct to error reporting by exception

HPX_THROW_EXCEPTION

Defined in header hpx/exception.hpp[864].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *HPX_THROW_BAD_ALLOC*
- *HPX_THROWS_IF*

HPX_THROW_EXCEPTION(errcode, f, ...)

Throw a *hpx::exception* initialized from the given parameters.

The macro *HPX_THROW_EXCEPTION* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter `errcode` holds the hpx::error code the new exception should encapsulate. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

```
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_EXCEPTION(hpx::error::no_success, "raise_exception",
        "simulated error");
}
```

Example:

HPX_THROW_BAD_ALLOC

Defined in header hpx/exception.hpp[865].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *HPX_THROW_EXCEPTION*
- *HPX_THROWS_IF*

---

[864] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/exception.hpp

[865] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/exception.hpp

HPX_THROW_BAD_ALLOC(f)

Throw a hpx::bad_alloc_exception initialized from the given parameters.

The macro *HPX_THROW_BAD_ALLOC* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter `errcode` holds the hpx::error code the new exception should encapsulate. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

```
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_BAD_ALLOC("raise_exception", "simulated error");
}
```

Example:

HPX_THROWS_IF

Defined in header hpx/exception.hpp[866].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *HPX_THROW_EXCEPTION*
- *HPX_THROW_BAD_ALLOC*

HPX_THROWS_IF(ec, errcode, f, ...)

Either throw a *hpx::exception* or initialize hpx::error_code from the given parameters.

The macro *HPX_THROWS_IF* can be used to either throw a hpx::exception or to initialize a hpx::error_code from the given parameters. If &ec == &hpx::throws, the semantics of this macro are equivalent to *HPX_THROW_EXCEPTION*. If &ec != &hpx::throws, the hpx::error_code instance `ec` is initialized instead.

The parameter `errcode` holds the hpx::error code from which the new exception should be initialized. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

hpx/errors/error.hpp

Defined in header hpx/errors/error.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

`HPX_ERROR_UNSCOPED_ENUM_DEPRECATION_MSG`

namespace **`hpx`**

Enums

enum class **`error`** : *std*::int16_t

Possible error conditions.

This enumeration lists all possible error conditions which can be reported from any of the API functions.

Values:

enumerator **`success`**

The operation was successful.

enumerator **`no_success`**

The operation did failed, but not in an unexpected manner.

enumerator **`not_implemented`**

The operation is not implemented.

enumerator **`out_of_memory`**

The operation caused an out of memory condition.

enumerator **`bad_action_code`**

enumerator **`bad_component_type`**

The specified component type is not known or otherwise invalid.

enumerator **`network_error`**

A generic network error occurred.

enumerator **`version_too_new`**

The version of the network representation for this object is too new.

enumerator **`version_too_old`**

The version of the network representation for this object is too old.

enumerator **`version_unknown`**

The version of the network representation for this object is unknown.

enumerator **`unknown_component_address`**

enumerator **`duplicate_component_address`**

The given global id has already been registered.

enumerator **`invalid_status`**

The operation was executed in an invalid status.

enumerator **`bad_parameter`**

One of the supplied parameters is invalid.

enumerator **`internal_server_error`**

enumerator **`service_unavailable`**

enumerator **`bad_request`**

enumerator **`repeated_request`**

enumerator **`lock_error`**

enumerator **`duplicate_console`**

There is more than one console locality.

enumerator **`no_registered_console`**

There is no registered console locality available.

enumerator **`startup_timed_out`**

enumerator **`uninitialized_value`**

enumerator **`bad_response_type`**

enumerator **`deadlock`**

enumerator **`assertion_failure`**

enumerator **`null_thread_id`**

Attempt to invoke an API function from a non-HPX thread.

enumerator **`invalid_data`**

enumerator **`yield_aborted`**

The yield operation was aborted.

enumerator **`dynamic_link_failure`**

enumerator **`commandline_option_error`**

One of the options given on the command line is erroneous.

enumerator **`serialization_error`**

There was an error during serialization of this object.

enumerator **`unhandled_exception`**

An unhandled exception has been caught.

enumerator **`kernel_error`**

The OS kernel reported an error.

enumerator **`broken_task`**

The task associated with this future object is not available anymore.

enumerator **`task_moved`**

The task associated with this future object has been moved.

enumerator **`task_already_started`**

The task associated with this future object has already been started.

enumerator **`future_already_retrieved`**

The future object has already been retrieved.

enumerator **`promise_already_satisfied`**

The value for this future object has already been set.

enumerator **`future_does_not_support_cancellation`**

The future object does not support cancellation.

enumerator **`future_can_not_be_cancelled`**

The future can't be canceled at this time.

enumerator **`no_state`**

The future object has no valid shared state.

enumerator **`broken_promise`**

The promise has been deleted.

enumerator **`thread_resource_error`**

enumerator **`future_cancelled`**

enumerator **`thread_cancelled`**

enumerator **`thread_not_interruptable`**

enumerator **`duplicate_component_id`**

The component type has already been registered.

enumerator **`unknown_error`**

An unknown error occurred.

enumerator **`bad_plugin_type`**

The specified plugin type is not known or otherwise invalid.

enumerator **`filesystem_error`**

The specified file does not exist or other filesystem related error.

enumerator **`bad_function_call`**

equivalent of std::bad_function_call

enumerator **`task_canceled_exception`**

parallel::task_canceled_exception

enumerator **`task_block_not_active`**

task_region is not active

enumerator **`out_of_range`**

Equivalent to std::out_of_range.

enumerator **`length_error`**

Equivalent to std::length_error.

enumerator **`migration_needs_retry`**

migration failed because of global race, retry

enumerator **`stale_state`**

The queried state may be stale, e.g. because no state has been recorded yet or a preceding notification has not yet been delivered

enumerator **`target_fenced`**

A dispatch was deliberately and correctly refused because the target had already latched a terminal lifecycle event; this is a final rejection, not a staleness signal, and should not be retried enumerator **future_wait_timed_out**

future wait timed out

enumerator **locality_was_disconnected**

the requested target locality was disconnected

enumerator **future_uncompleted**

future was resumed while being empty

hpx/errors/macros.hpp

Defined in header hpx/errors/macros.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_THROW_EXCEPTION(errcode, f, ...)

Throw a *hpx::exception* initialized from the given parameters.

The macro *HPX_THROW_EXCEPTION* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter `errcode` holds the hpx::error code the new exception should encapsulate. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

```
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_EXCEPTION(hpx::error::no_success, "raise_exception",
       "simulated error");
}
```

Example:

HPX_THROW_EXCEPTION_MODE(errcode, mode, f, ...)

Throw a *hpx::exception* initialized from the given parameters.

The macro *HPX_THROW_EXCEPTION_MODE* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter `errcode` holds the hpx::error code the new exception should encapsulate. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate. The `throwmode` parameter allows to specify the type of the thrown exception.

```
void raise_exception() {
    // Throw a hpx::exception initialized from the given parameters.
    HPX_THROW_EXCEPTION_MODE(hpx::error::no_success,
       hpx::throwmode::lighweight, "raise_exception",
       "simulated error");
}
```

Example:

HPX_THROW_BAD_ALLOC(f)

Throw a hpx::bad_alloc_exception initialized from the given parameters.

The macro *HPX_THROW_BAD_ALLOC* can be used to throw a *hpx::exception*. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter `errcode` holds the hpx::error code the new exception should encapsulate. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

```
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_BAD_ALLOC("raise_exception", "simulated error");
}
```

Example:

HPX_THROWS_IF(ec, errcode, f, ...)

Either throw a *hpx::exception* or initialize hpx::error_code from the given parameters.

The macro *HPX_THROWS_IF* can be used to either throw a hpx::exception or to initialize a hpx::error_code from the given parameters. If &ec == &hpx::throws, the semantics of this macro are equivalent to *HPX_THROW_EXCEPTION*. If &ec != &hpx::throws, the hpx::error_code instance `ec` is initialized instead.

The parameter `errcode` holds the hpx::error code from which the new exception should be initialized. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

HPX_THROWS_BAD_ALLOC_IF(ec, f)

Either throw a hpx::bad_alloc_exception or hpx::error_code to out_of_memory.

The macro *HPX_THROWS_BAD_ALLOC_IF* can be used to either throw a *hpx::bad_alloc_exception* or to initialize a hpx::error_code to hpx::error::out_of_memory. If &ec == &hpx::throws, the semantics of this macro are equivalent to *HPX_THROW_BAD_ALLOC*. If &ec != &hpx::throws, the hpx::error_code instance `ec` is initialized instead.

HPX_DEFINE_ERROR_INFO(NAME, TYPE)

hpx/errors/exception_fwd.hpp

Defined in header hpx/errors/exception_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Enums

enum class **throwmode** : *std*::uint8_t

Encode error category for new *error_code*.

Values:

enumerator **plain**

enumerator **rethrow**

enumerator **lightweight**

Functions

constexpr bool **operator&**(*throwmode* lhs, *throwmode* rhs) noexcept

Variables

error_code **throws**

Predefined *error_code* object used as "throw on error" tag.

The predefined *hpx::error_code* object *hpx::throws* is supplied for use as a "throw on error" tag.

Functions that specify an argument in the form '*error_code*& ec=throws' (with appropriate namespace qualifiers), have the following error handling semantics:

If &ec != &throws and an error occurred: ec.value() returns the implementation specific error number for the particular error that occurred and ec.category() returns the error_category for ec.value().

If &ec != &throws and an error did not occur, ec.clear().

If an error occurs and &ec == &throws, the function throws an exception of type hpx::exception or of a type derived from it. The exception's *get_errorcode()* member function returns a reference to a hpx::error_code object with the behavior as specified above.

execution

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/execution/executors/adaptive_static_chunk_size.hpp

Defined in header hpx/execution/executors/adaptive_static_chunk_size.hpp.

hpx::execution::experimental::guided_chunk_size

Defined in header hpx/execution.hpp[869].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **guided_chunk_size**

Iterations are dynamically assigned to threads in blocks as threads request those until no blocks remain to be assigned. Similar to dynamic_chunk_size except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to *number_of_iterations* / *number_of_cores*. Subsequent blocks are proportional to *number_of_iterations_remaining* / *number_of_cores*. The optional chunk size parameter defines the minimum block size. The default chunk size is 1.

> **Note**
>
> This executor parameters type is equivalent to OpenMP's GUIDED scheduling directive.

hpx/execution/executors/default_parameters.hpp

Defined in header hpx/execution/executors/default_parameters.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

struct **default_parameters**

#include <default_parameters.hpp> Loop iterations are divided into pieces of size *chunk_size* and then assigned to threads. If *chunk_size* is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

> **Note**
>
> This executor parameters type is equivalent to OpenMP's STATIC scheduling directive.

> **Note**
>
> If HPX was configured with HPX_WITH_TASK_SIZE_DEFAULT_PARAMETERS, this type is derived from task_size_chunk_size*:* a loop body that has a task size (see *hpx::task_size*) is chunked based on it, all others as described above.

---

[869] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/execution.hpp

Public Functions

constexpr **`default_parameters()`** noexcept = default

Construct a default_parameters executor parameters object

Note

By default, the number of loop iterations is determined from the number of available cores and the overall number of loop iterations to schedule.

hpx/execution/executors/rebind_policy.hpp

Defined in header hpx/execution/executors/rebind_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

rebind_executor and the customization points for rebinding an execution policy's executor and executor parameters independently of one another.

rebind_executor_t rebinds both at once and requires the policy to be shaped as Derived<Executor, Parameters>. rebind_policy_executor and rebind_policy_parameters can be specialized per axis, so a policy that carries extra state or has a different shape can still be rebound. Their defaults forward to rebind_executor_t. The matching construction-side customization points are in create_rebound_policy.hpp.

namespace **`hpx`**

namespace **`execution`**

namespace **`experimental`**

Typedefs

template<typename **`ExPolicy`**, typename **`Executor`**, typename **`Parameters`**>

using **`rebind_executor_t`** = typename *rebind_executor*<*ExPolicy*, *Executor*, *Parameters*>::type

template<typename **`Policy`**, typename **`Executor`**>

using **`rebind_policy_executor_t`** = *hpx*::*execution*::detail::validated_rebind_policy_executor<*std*::decay_t<*Policy*>, *std*::decay_t<*Executor*>>::type

Policy rebound to Executor, keeping its executor parameters.

Applies *rebind_policy_executor* and checks that Executor's execution category is not weaker than Policy's, also for direct specializations of *rebind_policy_executor*. If the check fails, or *rebind_policy_executor* has no nested `type`, the alias does not name a type.

template<typename **`Policy`**, typename **`Parameters`**>

using **`rebind_policy_parameters_t`** = *hpx*::*execution*::detail::validated_rebind_policy_parameters<*std*::decay_t<*Policy*>, *std*::decay_t<*Parameters*>>::type

Policy rebound to Parameters, keeping its executor.

Applies *rebind_policy_parameters* and checks that the execution category of Policy's current executor is not weaker than Policy's, also for direct specializations of *rebind_policy_parameters*. If the check fails, or *rebind_policy_parameters* has no nested `type`, the alias does not name a type.

Variables

template<typename Policy, typename Executor,
typename Parameters> concept rebind_policy_order_independent = std::is_same_v< re
Executor>,Parameters>,
rebind_policy_executor_t<rebind_policy_parameters_t<Policy, Parameters>,
Executor>>

Whether rebinding the executor then the parameters gives the same type as the other order.

Not satisfied if either order can't be rebound, so it can be used in a constraint without failing to compile. Satisfied for the defaults whenever both orders can be rebound. A policy that specializes either customization point should static_assert it.

template<typename **Policy**, typename **Executor**, typename **Parameters**>

constexpr bool **rebind_policy_order_independent_v** =
rebind_policy_order_independent<*Policy*, *Executor*, *Parameters*>

Value of rebind_policy_order_independent.

template<typename **ExPolicy**, typename **Executor**, typename **Parameters**>

struct **rebind_executor**

#include <rebind_policy.hpp> Rebind the type of executor used by an execution policy. The execution category of Executor shall not be weaker than that of ExecutionPolicy.

Public Types

using **type** = typename policy_type::template rebind<executor_type, parameters_type>::type

The type of the rebound execution policy.

template<typename **Policy**, typename **Executor**>

struct **rebind_policy_executor** : public
hpx::*execution*::detail::default_rebind_policy_executor<*std*::decay_t<*Policy*>,
std::decay_t<*Executor*>>

#include <rebind_policy.hpp> Customization point for rebinding an execution policy to a new executor, keeping its executor parameters.

The default needs a nested `rebind<Executor_, Parameters_>::type`, as hpx::execution::detail::execution_policy provides, and has no nested `type` otherwise. Specialize it for policies that don't fit that shape. Use it through rebind_policy_executor_t, which also checks that Executor's execution category is not weaker than Policy's.

A specialization that can't rebind Policy to a given Executor should leave out the nested `type` instead of failing to compile, so that rebind_policy_executor_t, create_rebound_policy_executor and rebind_policy_order_independent_v can detect it.

Template Parameters

- **`Policy`** – The execution policy type being rebound.
- **`Executor`** – The executor type Policy should be rebound to.

template<typename **`Policy`**, typename **`Parameters`**>

struct **`rebind_policy_parameters`** : public *hpx*::*execution*::detail::default_rebind_policy_parameters<*std*::decay_t<*Policy*>, *std*::decay_t<*Parameters*>>

#include <rebind_policy.hpp> Customization point for rebinding an execution policy to new executor parameters, keeping its executor.

The default needs a nested `executor_type` and `rebind<Executor_, Parameters_>::type`, and has no nested `type` otherwise. Specialize it for policies that don't fit that shape. Use it through rebind_policy_parameters_t.

A specialization that can't rebind Policy to given Parameters should leave out the nested `type` instead of failing to compile, so that rebind_policy_parameters_t, create_rebound_policy_parameters and rebind_policy_order_independent_v can detect it.

Template Parameters

- **`Policy`** – The execution policy type being rebound.
- **`Parameters`** – The executor parameters type Policy should be rebound to.

hpx/execution/executors/rebind_executor.hpp

Defined in header hpx/execution/executors/rebind_executor.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

rebind_executor, rebind_executor_t and create_rebound_policy.

rebind_executor and rebind_executor_t are defined in rebind_policy.hpp, next to the per-axis customization points built on top of them, and create_rebound_policy is defined in create_rebound_policy.hpp. This header includes both, so code that includes it directly keeps getting everything it provided before.

hpx::execution::experimental::persistent_auto_chunk_size

Defined in header hpx/execution.hpp[870].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **`persistent_auto_chunk_size`**

Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

---

[870] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/execution.hpp

hpx::execution::experimental::auto_chunk_size

Defined in header hpx/execution.hpp[871].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **auto_chunk_size**

Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

hpx::execution::experimental::task_size_chunk_size

Defined in header hpx/execution.hpp[872].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **task_size_chunk_size**

Loop iterations are divided into chunks based on the task size of the loop body (see *hpx::task_size*). The run time a size stands for (see *hpx::task_size_duration*) is taken as the run time of one iteration, nothing is measured. The loop runs on as many cores as can be given *chunks_per_core* chunks of at least *min_chunk_time* each, at least on one, and then on the calling thread if it is only one chunk.

A loop body without a size is chunked as with the default parameters.

hpx/execution/executors/execution_information.hpp

Defined in header hpx/execution/executors/execution_information.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

hpx::execution::experimental::static_chunk_size

Defined in header hpx/execution.hpp[873].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **static_chunk_size**

Loop iterations are divided into pieces of size *chunk_size* and then assigned to threads. If *chunk_size* is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

> **Note**
>
> This executor parameters type is equivalent to OpenMP's STATIC scheduling directive.

---

[873] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/execution.hpp

hpx/execution/executors/create_rebound_policy.hpp

Defined in header hpx/execution/executors/create_rebound_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

create_rebound_policy and the per-axis construction customization points it dispatches to.

rebind_executor.hpp includes this header, so code that includes rebind_executor.hpp directly still gets create_rebound_policy.

namespace **hpx**

namespace **execution**

namespace **experimental**

Variables

```
template<typename Policy,
typename Executor> concept rebound_policy_executor_constructible  =hpx::executor_any<Execut
std::decay_t<Executor>>::call(std::forward<  Policy  >(  policy  ),
std::forward<  Executor  >(  exec  ))} -> std::same_as<rebind_policy_executor_t<Policy,
Executor>>;}
```

Whether a policy of type Policy can be rebound to an executor of type Executor through create_rebound_policy_executor.

Satisfied if Executor is an executor and *construct_rebound_policy_executor* accepts the forwarded policy and executor and returns rebind_policy_executor_t<Policy, Executor>, so in particular only if that type exists.

```
template<typename Policy,
typename Parameters> concept rebound_policy_parameters_constructible  =hpx::executor_parame
std::decay_t<Parameters>>::call(std::forward<  Policy  >(  policy  ),
std::forward<  Parameters  >(  params  ))} -> std::same_as<rebind_policy_parameters_t<Polic
Parameters>>;}
```

Whether a policy of type Policy can be rebound to executor parameters of type Parameters through create_rebound_policy_parameters.

Mirrors rebound_policy_executor_constructible along the parameters axis.

constexpr struct *hpx*::*execution*::*experimental*::*create_rebound_policy_executor_t*
create_rebound_policy_executor

constexpr struct *hpx*::*execution*::*experimental*::*create_rebound_policy_parameters_t*
create_rebound_policy_parameters

constexpr struct *hpx*::*execution*::*experimental*::*create_rebound_policy_t* **create_rebound_policy**

template<typename **Policy**, typename **Executor**>

struct **`construct_rebound_policy_executor`**

#include <create_rebound_policy.hpp> Customization point controlling how an execution policy rebound to a new executor is constructed from the original policy.

rebind_policy_executor only computes the rebound type. A policy that carries additional state, or that cannot be constructed from just (executor, parameters), specializes this template to build the rebound policy itself. `call` receives the original policy, forwarded with the value category it was passed with, so any such state can be carried over, and the new executor.

`call` must return exactly rebind_policy_executor_t<Policy, Executor>. It must also be SFINAE-friendly: create_rebound_policy_executor checks the call in a requires expression, so a specialization that can't handle some arguments has to make the call expression itself ill-formed, for example by constraining `call` or by giving it a return type that depends on its own template parameters. A failure inside the body of `call`, or in a member declaration that depends only on Policy and Executor, is a hard error.

The default constructs the rebound policy from the new executor and the original policy's parameters().

Template Parameters

- **`Policy`** – The (decayed) execution policy type being rebound.
- **`Executor`** – The (decayed) executor type Policy is rebound to.

Public Static Functions

template<typename **`Policy_`**, typename **`Executor_`**>
static inline constexpr *rebind_policy_executor_t*<*Policy*, *Executor_*> **`call`**(*Policy_* &&policy, *Executor_* &&exec)

template<typename **`Policy`**, typename **`Parameters`**>

struct **`construct_rebound_policy_parameters`**

#include <create_rebound_policy.hpp> Customization point controlling how an execution policy rebound to new executor parameters is constructed from the original policy.

Mirrors *construct_rebound_policy_executor* along the parameters axis, with the same requirements: `call` must return exactly rebind_policy_parameters_t<Policy, Parameters> and be SFINAE-friendly.

The default constructs the rebound policy from the original policy's executor() and the new parameters.

Template Parameters

- **`Policy`** – The (decayed) execution policy type being rebound.
- **`Parameters`** – The (decayed) executor parameters type Policy is rebound to.

Public Static Functions

template<typename **`Policy_`**, typename **`Parameters_`**>
static inline constexpr *rebind_policy_parameters_t*<*Policy*, *Parameters_*> **`call`**(*Policy_* &&policy, *Parameters_* &&parameters)

struct **create_rebound_policy_executor_t**

#include <create_rebound_policy.hpp> Rebind the executor of *policy* to *exec* and construct the result through *construct_rebound_policy_executor*.

Only participates in overload resolution if rebound_policy_executor_constructible<Policy, Executor> is satisfied.

Public Functions

template<typename **Policy**, typename **Executor**>
inline constexpr *rebind_policy_executor_t*<*Policy*, *Executor*> **operator()**(*Policy* &&policy, *Executor* &&exec) const

struct **create_rebound_policy_parameters_t**

#include <create_rebound_policy.hpp> Rebind the executor parameters of *policy* to *parameters* and construct the result through *construct_rebound_policy_parameters*.

Only participates in overload resolution if rebound_policy_parameters_constructible<Policy, Parameters> is satisfied.

Public Functions

template<typename **Policy**, typename **Parameters**>
inline constexpr *rebind_policy_parameters_t*<*Policy*, *Parameters*> **operator()**(*Policy* &&policy, *Parameters* &&parameters) const

struct **create_rebound_policy_t**

Public Functions

template<typename **ExPolicy**, typename **Executor**, typename **Parameters**>
inline constexpr decltype(auto) **operator()**(*ExPolicy* &&policy, *Executor* &&exec, *Parameters* &&parameters) const

Rebind both the executor and the executor parameters of *policy*, one axis at a time through create_rebound_policy_executor and create_rebound_policy_parameters.

The executor is rebound first, so the specializations of both axes are honored and state that *policy* carries is kept, the same as when rebinding a single axis.

template<typename **ExPolicy**, typename **Executor**>
inline constexpr decltype(auto) **operator()**(*ExPolicy* &&policy, *Executor* &&exec) const

Rebind only the executor of *policy*, through create_rebound_policy_executor.

template<typename **ExPolicy**, typename **Parameters**>
inline constexpr decltype(auto) **operator()**(*ExPolicy* &&policy, *Parameters* &&parameters) const

Rebind only the executor parameters of *policy*, through create_rebound_policy_parameters.

Param params
[in] The executor parameters object to use as a fallback if the executor does not expose

Param exec
[in] The executor object which will be used for scheduling of the loop iterations.

Param num_elements
[in] The overall number of elements for the algorithm.

Param num_cores
[in] The overall number of cores to utilize for the algorithm.

Param num_chunks
[in] The overall number of chunks for the algorithm.

Param chunk_size
[in] The size of the chunks created for the algorithm.

Public Functions

template<typename **Parameters**, typename **Executor**>
inline decltype(auto) **operator()**(*Parameters* &&params, *Executor* &&exec, *std*::size_t num_elements, *std*::size_t num_cores, *std*::size_t num_chunks, *std*::size_t chunk_size) const

template<>

struct **is_scheduling_property**<*with_processing_units_count_t*> : public *std*::true_type

hpx::execution::experimental::max_num_chunks

Defined in header hpx/execution.hpp[874].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **max_num_chunks**

Loop iterations are divided into not more than *num_chunks* partitions that are assigned to threads. If *num_chunks* is not specified, the number of chunks is determined based on the number of available cores.

hpx::execution::experimental::dynamic_chunk_size

Defined in header hpx/execution.hpp[875].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **dynamic_chunk_size**

Loop iterations are divided into pieces of size *chunk_size* and then dynamically scheduled among the threads; when a thread finishes one chunk, it is dynamically assigned another If *chunk_size* is not specified, the default chunk size is 1.

namespace **experimental**

hpx/execution/algorithms/sender_future.hpp

Defined in header hpx/execution/algorithms/sender_future.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Converts any P2300 stdexec sender into an hpx::future<T>.

Usage:

```
// Explicit T:
auto sender = stdexec::just(42) | stdexec::then([](int x){ return x; });
hpx::future<int> f =
    hpx::execution::experimental::as_future<int>(std::move(sender));
int val = f.get();   // == 42
```

struct **async_invoke_t**

#include <execution.hpp> Asynchronously invoke the given set of nullary functions, each on its own execution agent

This creates a group of function invocations whose ordering is given by the execution_category associated with the executor.

All exceptions thrown by invocations of the functions are reported in a manner consistent with parallel algorithm execution through the returned future.

> **Note**
>
> This calls exec.async_invoke(fs…) if it exists; otherwise it executes async_execute(fs) for each fs.

Param exec
[in] The executor object to use for scheduling of the functions *fs*.

Param fs
[in] The functions which will be scheduled using the given executor.

Return
The return type of *executor_type::async_invoke* if defined by *executor_type*. Otherwise, a future<void> representing finishing the execution of all functions *fs*.

Public Functions

hpx/executors/thread_pool_continues_on_sender.hpp

Defined in header hpx/executors/thread_pool_continues_on_sender.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Domain-optimized continues_on sender for HPX thread pool schedulers.

When stdexec::continues_on is applied with an HPX thread_pool_scheduler, the generic stdexec implementation creates two operation states: one for the source sender and one for the scheduler hop (schedule_from). This double-state overhead adds ~1 us per task in microbenchmarks.

This header provides a custom sender that replaces the generic path by:

1. Connecting the source sender to a lightweight receiver that captures the downstream receiver and the scheduler.
2. On set_value: if we are already on the same HPX thread pool, forwarding inline; otherwise, posting a single HPX task to forward the values.

This eliminates the intermediate __storage_for_t, the second operation state, and the run_loop overhead.

hpx::execution::experimental::get_parallel_scheduler

Defined in header hpx/execution.hpp[876].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::execution::experimental::parallel_scheduler*
- *hpx::execution::experimental::parallel_scheduler_domain*

parallel_scheduler `hpx::execution::experimental::`**`get_parallel_scheduler`**`()`

Return a parallel_scheduler that schedules on the default HPX thread pool.

This is HPX's implementation of the P2079 `std::execution::get_parallel_scheduler()` entry point. Work started on the returned scheduler uses the same worker threads as the default pool rather than a separate system thread pool.

Note

For a named resource-partitioner pool, use the overload that takes `hpx::threads::thread_pool_base`&.

Returns

A scheduler bound to HPX's default thread pool.

---

[876] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/execution.hpp

parallel_scheduler `hpx::execution::experimental::get_parallel_scheduler`(*hpx*::*threads*::*thread_pool_base* &pool)

Return a parallel_scheduler that runs work on `pool`.

Look named pools up with `hpx::resource::get_thread_pool`. A misspelled or unknown name throws *`hpx::exception`*; it does not produce undefined behavior.

Parameters

`pool` – HPX thread pool that should execute scheduled work.

Pre

`pool` must outlive the returned scheduler and every operation started on it. The scheduler stores a non-owning pointer; it does not extend the pool's lifetime. This precondition is not enforced at runtime (caller responsibility). Debug builds assert that `pool` currently reports at least one OS thread.

Returns

A scheduler bound to `pool`.

hpx::execution::experimental::parallel_scheduler

Defined in header hpx/execution.hpp[877].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **`parallel_scheduler`**

P2079 parallel scheduler.

A replaceable `std::execution` scheduler that schedules work on an HPX thread pool through a *parallel_scheduler_backend*. The default backend wraps HPX's `thread_pool_policy_scheduler` so callers can use *get_parallel_scheduler* without managing pools themselves.

Schedulers compare equal when they share the same backend instance (P2079 pointer equality). Forward-progress guarantee is `parallel`.

Obtain instances with *get_parallel_scheduler* (default pool) or *get_parallel_scheduler(pool)* (named resource-partitioner pool).

struct **parallel_scheduler_domain** : public *hpx*::*execution*::*experimental*::detail::sync_wait_domain

Domain associated with parallel_scheduler.

Implements P2079 sender transformations for bulk algorithms that complete on a parallel_scheduler. Fast-path bulk work is forwarded to HPX's optimized `thread_pool_bulk_sender`; custom backends go through the virtual *parallel_scheduler_backend* interface.

hpx/executors/scheduler_executor.hpp

Invokes the given callable object f with the content of the sequenced type t (tuples, pairs).

> **Note**
>
> This function is similar to `std::apply` (C++17). The difference between *`hpx::invoke`* and *`hpx::invoke_fused`* is that the later unpacks the tuples while the former cannot. Turning a tuple into a parameter pack is not a trivial operation which makes *`hpx::invoke_fused`* rather useful.

Parameters

- **`f`** – Must be a callable object. If f is a member function pointer, the first argument in the sequenced type will be treated as the callee (this object).
- **`t`** – A type whose contents are accessible through a call to *hpx::get*.

Throws

`std``::exception` – like objects thrown by call to object f with the arguments contained in the sequenceable type t.

Returns

The result of the callable object when it's called with the content of the given sequenced type.

---

[890] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

hpx::invoke_fused_r

Defined in header hpx/functional.hpp[891].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::invoke_fused*

template<typename **R**, typename **F**, typename **Tuple**>
constexpr *R* `hpx::`**`invoke_fused_r`**`(`*F* &&f, *Tuple* &&t`)` noexcept(noexcept(detail::invoke_fused_impl(detail::fused_index_pack_t<*Tuple*>{}, *std*::forward<*F*>(*f*), *std*::forward<*Tuple*>(*t*))))

Invokes the given callable object f with the content of the sequenced type t (tuples, pairs).

Note

This function is similar to `std::apply` (C++17). The difference between *`hpx::invoke`* and *`hpx::invoke_fused`* is that the later unpacks the tuples while the former cannot. Turning a tuple into a parameter pack is not a trivial operation which makes *`hpx::invoke_fused`* rather useful.

Note

The difference between *`hpx::invoke_fused`* and *`hpx::invoke_fused_r`* is that the later allows to specify the return type as well.

Parameters

- **`f`** – Must be a callable object. If f is a member function pointer, the first argument in the sequenced type will be treated as the callee (this object).
- **`t`** – A type whose contents are accessible through a call to *hpx::get*.

Throws

`std``::exception` – like objects thrown by call to object f with the arguments contained in the sequenceable type t.

Template Parameters

`R` – The result type of the function when it's called with the content of the given sequenced type.

Returns

The result of the callable object when it's called with the content of the given sequenced type.

class **function**

Class template *hpx::function* is a general-purpose polymorphic function wrapper. Instances of *hpx::function* can store, copy, and invoke any CopyConstructible Callable target &#8212; functions, lambda expressions, bind expressions, or other function objects, as well as pointers to member functions and pointers to data members. The stored callable object is called the target of *hpx::function*. If an *hpx::function* contains no target, it is called empty. Invoking the target of an empty *hpx::function* results in *hpx::error::bad_function_call* exception being thrown. *hpx::function* satisfies the requirements of CopyConstructible and CopyAssignable.

hpx::mem_fn

Defined in header hpx/functional.hpp[898].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

---

[900] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

[901] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

hpx::function_ref

Defined in header hpx/functional.hpp[902].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Sig**>

class **function_ref**

function_ref class is a vocabulary type with reference semantics for passing entities to call.

An example use case that benefits from higher-order functions is `retry(n,f)` which attempts to call `f` up to `n` times synchronously until success. This example might model the real-world scenario of repeatedly querying a flaky web service.

```
using payload = std::optional< /* ... */ >;
// Repeatedly invokes `action` up to `times` repetitions.
// Immediately returns if `action` returns a valid `payload`.
// Returns `std::nullopt` otherwise.
payload retry(size_t times, /* ????? */ action);
```

The passed-in action should be a callable entity that takes no arguments and returns a payload. This can be done with function pointers, *hpx::function* or a template but it is much simpler with *function_ref* as seen below:

```
payload retry(size_t times, function_ref<payload()> action);
```

hpx::move_only_function

Defined in header hpx/functional.hpp[903].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Sig**, bool **Serializable** = false>

class **move_only_function**

Class template *hpx::move_only_function* is a general-purpose polymorphic function wrapper. *hpx::move_only_function* objects can store and invoke any constructible (not required to be move constructible) Callable target &#8212; functions, lambda expressions, bind expressions, or other function objects, as well as pointers to member functions and pointers to member objects.

The stored callable object is called the target of *hpx::move_only_function*. If an *hpx::move_only_function* contains no target, it is called empty. Unlike *hpx::function*, invoking an empty *hpx::move_only_function* results in undefined behavior.

hpx::move_only_functions supports every possible combination of cv-qualifiers, ref-qualifiers, and noexcept-specifiers not including volatile provided in its template parameter. These qualifiers and specifier (if any) are added to its operator(). *hpx::move_only_function* satisfies the requirements of MoveConstructible and MoveAssignable, but does not satisfy CopyConstructible or CopyAssignable.

---

[902] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

[903] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

hpx::is_placeholder

Defined in header hpx/functional.hpp[904].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

struct **is_placeholder**

If `T` is a standard, Boost, or HPX placeholder (_1, _2, _3, …) then this template is derived from `std::integral_constant<int,1>`, `std::integral_constant<int,2>`, `std::integral_constant<int,3>`, respectively. Otherwise, it is derived from `std::integral_constant<int,0>`.

The template may be specialized for any user-defined `T` type: the specialization must satisfy *UnaryTypeTrait* with base characteristic of `std::integral_constant<int,N>` with N>0 to indicate that `T` should be treated as N'th placeholder type. `hpx::bind` uses *`hpx::is_placeholder`* to detect placeholders for unbound arguments.

hpx::is_bind_expression

Defined in header hpx/functional.hpp[905].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>

struct **is_bind_expression** : public *std*::is_bind_expression<*T*>

If `T` is the type produced by a call to `hpx::bind`, this template is derived from `std::true_type`. For any other type, this template is derived from `std::false_type`.

This template may be specialized for a user-defined type `T` to implement *UnaryTypeTrait* with base characteristic of `std::true_type` to indicate that `T` should be treated by `hpx::bind` as if it were the type of a bind subexpression: when a bind-generated function object is invoked, a bound argument of this type will be invoked as a function object and will be given all the unbound arguments passed to the bind-generated object.

Subclassed by hpx::is_bind_expression< T const >

hpx/functional/traits/get_task_size.hpp

Defined in header hpx/functional/traits/get_task_size.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

---

[904] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

[905] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

Defines

HPX_TASK_SIZE_BUILTIN_OPERATION(op)

HPX_TASK_SIZE_BUILTIN_RANGES_OPERATION(op)

namespace **hpx**

Top level namespace.

namespace **threads**

Enums

enum class **task_size** : *std*::uint8_t

The expected run time of a task, a hint the scheduler may use. A task with an unknown size is scheduled as it would be without the hint. The sizes are ordered by run time, see task_size_duration.

Values:

enumerator **unknown**

enumerator **nano**

about a nanosecond, mostly for loop bodies

enumerator **small_**

the underscore is to work around 'small' being defined to char on Windows

enumerator **medium**

enumerator **large**

Functions

constexpr *std*::chrono::nanoseconds **task_size_duration**(*task_size* const size) noexcept

The run time a task of the given `size` stands for. Each size stands for a hundred times the run time of the one below it: nano about 1 ns, small about 100 ns, medium about 10 us, large about 1 ms or more. An unknown size gives a duration of zero. Callers should rely on std::chrono arithmetic only, not on the unit or the count of the returned duration, which may change once tasks can carry real run times.

constexpr *task_size* **bulk_task_size**(*task_size* const size, *std*::size_t const calls) noexcept

The size of a task that calls a function of the given `size` `calls` times, for instance a hundred nano calls make a small task, a hundred small calls a medium one and a hundred medium calls a large one. The size of a task calling a function of unknown size is unknown.

namespace **traits**

template<typename **`F`**>
auto *`hpx`*`::experimental::`**`scope_success`**`(`*F* &&f`)`

The class template scope_success is a general-purpose scope guard intended to call its exit function when a scope is normally exited.

Template Parameters

`F` – type of stored exit function

Parameters

`f` – stored exit function

hpx::experimental::scope_fail

Defined in header hpx/experimental/scope.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`F`**>

auto *hpx*`::experimental::`**`scope_fail`**(*F* &&f)

The class template scope_fail is a general-purpose scope guard intended to call its exit function when a scope is exited via an exception.

Template Parameters

`F` – type of stored exit function

Parameters

`f` – stored exit function

futures

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::promise

Defined in header hpx/future.hpp[906].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **R**>

class **`promise`** : public *hpx*::detail::promise_base<*R*>

The class template *hpx::promise* provides a facility to store a value or an exception that is later acquired asynchronously via a *hpx::future* object created by the *hpx::promise* object. Note that the *hpx::promise* object is meant to be used only once. Each promise is associated with a shared state, which contains some state information and a result which may be not yet evaluated, evaluated to a value (possibly void) or evaluated to an exception. A promise may do three things with the shared state:

- make ready: the promise stores the result or the exception in the shared state. Marks the state ready and unblocks any thread waiting on a future associated with the shared state.
- release: the promise gives up its reference to the shared state. If this was the last such reference, the shared state is destroyed. Unless this was a shared state created by hpx::async which is not yet ready, this operation does not block.
- abandon: the promise stores the exception of type hpx::future_error with error code hpx::error::broken_promise, makes the shared state ready, and then releases it. The promise is the "push" end of the promise-future communication channel: the operation that stores a value in the shared state synchronizes-with (as defined in hpx::memory_order) the successful return from any function that is waiting on the shared state (such as hpx::future::get). Concurrent access to the same shared state may conflict otherwise: for example multiple callers of hpx::shared_future::get must either all be read-only or provide external synchronization.

hpx/futures/future_fwd.hpp

Defined in header hpx/futures/future_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Top level HPX namespace.

namespace **lcos**

namespace **lcos**

hpx::packaged_task

Defined in header hpx/future.hpp[907].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Sig**>

class **packaged_task**

The class template *hpx::packaged_task* wraps any Callable` target (function, lambda expression, bind expression, or another function object) so that it can be invoked asynchronously. Its return value or exception thrown is stored in a shared state which can be accessed through *hpx::future* objects. Just like *hpx::function*, *hpx::packaged_task* is a polymorphic, allocator-aware container: the stored callable target may be allocated on heap or with a provided allocator.

hpx::future

Defined in header hpx/future.hpp[908].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **R**>

---

[907] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

[908] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

class **future** : public *hpx*::*lcos*::detail::future_base<*future*<*R*>, *R*>

The class template *hpx::future* provides a mechanism to access the result of asynchronous operations:

- An asynchronous operation (created via hpx::async, *hpx::packaged_task*, or *hpx::promise*) can provide a *hpx::future* object to the creator of that asynchronous operation.
- The creator of the asynchronous operation can then use a variety of methods to query, wait for, or extract a value from the *hpx::future*. These methods may block if the asynchronous operation has not yet provided a value.
- When the asynchronous operation is ready to send a result to the creator, it can do so by modifying shared state (e.g. hpx::promise::set_value) that is linked to the creator's *hpx::future*. Note that *hpx::future* references shared state that is not shared with any other asynchronous return objects (as opposed to *hpx::shared_future*).

hpx::shared_future

Defined in header hpx/future.hpp[909].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::future*
- *hpx::make_future*
- *hpx::make_shared_future*

- *hpx::make_ready_future_alloc*
- *hpx::make_ready_future_at*
- *hpx::make_ready_future_after*
- *hpx::make_exceptional_future*

template<typename **R**>

class **shared_future** : public *hpx*::*lcos*::detail::future_base<*shared_future*<*R*>, *R*>

The class template *hpx::shared_future* provides a mechanism to access the result of asynchronous operations, similar to *hpx::future*, except that multiple threads are allowed to wait for the same shared state. Unlike *hpx::future*, which is only moveable (so only one instance can refer to any particular asynchronous result), *hpx::shared_future* is copyable and multiple shared future objects may refer to the same shared state. Access to the same shared state from multiple threads is safe if each thread does it through its own copy of a *shared_future* object.

- *hpx::make_exceptional_future*

template<typename **R**, typename **U**>
`hpx::future<R> hpx::make_future(hpx::future<U> &&f)`

Converts any future of type U to any other future of type R based on an existing conversion path from U to R.

template<typename **R**, typename **U**, typename **Conv**>
`hpx::future<R> hpx::make_future(hpx::future<U> &&f, Conv &&conv)`

Converts any future of type U to any other future of type R based on a given conversion function: R conv(U).

template<typename **R**, typename **U**>
`hpx::future<R> hpx::make_future(hpx::shared_future<U> f)`

Converts any *shared_future* of type U to any other future of type R based on an existing conversion path from U to R.

template<typename **R**, typename **U**, typename **Conv**>
`hpx::future<R> hpx::make_future(hpx::shared_future<U> f, Conv &&conv)`

Converts any future of type U to any other future of type R based on an existing conversion path from U to R.

hpx::make_shared_future

Defined in header hpx/future.hpp[911].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

const
&a,
Ts&&...
ts)

Creates a pre-initialized future object with allocator (extension)

template<int **DeductionGuard** = 0, typename **Allocator**, typename **T**>
future<*hpx*::*util*::decay_unwrap_t<*T*>> `hpx::`**`make_ready_future_alloc`**(*Allocator* const &a, *T* &&init)

Creates a pre-initialized future object with an allocator.

Parameters

- **`a`** – The allocator used to create the future's shared state.
- **`init`** – The value used to initialize the future.

template<typename **Allocator**>
inline *future*<void> `hpx::`**`make_ready_future_alloc`**(*Allocator* const &a)

Creates a pre-initialized void future object with an allocator.

Parameters

`a` – The allocator used to create the future's shared state.

hpx::make_ready_future_at

Defined in header hpx/future.hpp[914].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

io_service

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/io_service/io_service_pool.hpp

Defined in header hpx/io_service/io_service_pool.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

class **io_service_pool**

#include <io_service_pool.hpp> A pool of io_service objects.

Public Functions

explicit **io_service_pool**(*std*::size_t pool_size = 2, *threads*::*policies*::callback_notifier const &notifier = *threads*::*policies*::callback_notifier(), char const *pool_name = "", char const *name_postfix = "")

Construct the io_service pool.

Parameters

- **pool_size** – [in] The number of threads to run to serve incoming requests
- **notifier** – [in]
- **pool_name** – [in]
- **name_postfix** – [in]

explicit **io_service_pool**(*threads*::*policies*::callback_notifier const &notifier, char const *pool_name = "", char const *name_postfix = "")

Construct the io_service pool.

Parameters

- **notifier** – [in]
- **pool_name** – [in]
- **name_postfix** – [in]

io_service_pool(*io_service_pool* const&) = delete

io_service_pool(*io_service_pool*&&) = delete

io_service_pool &**operator=**(*io_service_pool* const&) = delete

io_service_pool &**operator=**(*io_service_pool*&&) = delete

~io_service_pool()

bool **run**(bool join_threads = true, *std*::shared_ptr<*barrier*> startup = {}) const

Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to complete.

Parameters

- **join_threads** – [in] If true, wait for all pool threads to join before returning.

- **startup** – [in] Optional startup barrier used to synchronize pool worker thread startup with the caller. Its participant count must equal the number of pool worker threads plus one for the caller. The caller must call startup->*wait()* after invoking *run()*.

bool **run**(*std*::size_t num_threads, bool join_threads = true, *std*::shared_ptr<*barrier*> startup = {}) const

Run num_threads io_service objects in the pool. If join_threads is true this will also wait for all threads to complete.

Parameters

- **num_threads** – [in] The number of worker threads to start.
- **join_threads** – [in] If true, wait for all pool threads to join before returning.
- **startup** – [in] Optional startup barrier used to synchronize pool worker thread startup with the caller. Its participant count must equal num_threads plus one for the caller. The caller must call startup->*wait()* after invoking *run()*.

void **stop**() const

Stop all io_service objects in the pool.

void **join**() const

Join all io_service threads in the pool.

void **clear**() const

Clear all internal data structures.

void **wait**() const

Wait for all work to be done.

bool **stopped**() const

::asio::io_context &**get_io_service**(int index = -1) const

Get an io_service to use.

std::thread &**get_os_thread_handle**(*std*::size_t thread_num) const

access underlying thread handle

std::size_t **size**() const noexcept

Get number of threads associated with this I/O service.

void **thread_run**(*std*::size_t index, *std*::shared_ptr<*barrier*> startup = {}) const

Activate the thread *index* for this thread pool.

char const ***get_name**() const noexcept

Return name of this pool.

void **init**(*std*::size_t pool_size) const

Private Members

detail::io_service_pool_base ***pool_**

hpx/io_service/schedule_timer.hpp

Defined in header hpx/io_service/schedule_timer.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **io**

namespace **experimental**

Functions

template<typename **Rep**, typename **Period**>
auto **schedule_timer_after**(::asio::io_context &context, *std*::chrono::duration<*Rep*, *Period*> const duration) noexcept

Return a sender that completes after the supplied duration has elapsed.

The timer starts when the sender's operation state is started. Successful expiry produces `set_value()`, a stop request produces `set_stopped()`, and other timer failures produce `set_error(std::exception_ptr)`. The supplied I/O context must be run until the operation completes.

Parameters

- **context** – The Asio I/O context on which the timer is run.
- **duration** – The duration to wait after the operation is started.

Returns

A sender representing the timer operation.

inline auto **schedule_timer_at**(::asio::io_context &context, *std*::chrono::steady_clock::time_point const time_point) noexcept

Return a sender that completes at the supplied time point.

Successful expiry produces `set_value()`, a stop request produces `set_stopped()`, and other timer failures produce `set_error(std::exception_ptr)`. The supplied I/O context must be run until the operation completes.

Parameters

- **context** – The Asio I/O context on which the timer is run.
- **time_point** – The absolute time at which the sender should complete.

Returns

A sender representing the timer operation.

>
> This type is not thread-safe. It has to be protected from concurrent access by different threads by the code using instances of this type.

logging

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/logging/manipulator.hpp

Defined in header hpx/logging/manipulator.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

namespace **logging**

namespace **destination**

Destination is a manipulator. It contains a place where the message, after being formatted, is to be written to.

Some viable destinations are `destination::cout` (the console), `destination::file` (a file), a socket, etc.

struct **manipulator**

#include <manipulator.hpp> What to use as base class, for your destination classes.

Public Functions

virtual void **operator()**(message const&) = 0

inline virtual void **configure**(*std*::string const&)

Override this if you want to allow configuration through scripting.

That is, this allows configuration of your manipulator at run-time.

virtual **~manipulator**()

Protected Functions

manipulator() = default

namespace **formatter**

Formatter is a manipulator. It allows you to format the message before writing it to the destination(s)

Examples of formatters are: `formatter::time_t` (prepend the time), `formatter::high_precision_time_t` (prepend high-precision time), and `formatter::idx_t` (prepend the index of the message).

struct **manipulator**

#include <manipulator.hpp> What to use as base class, for your formatter classes.

Public Functions

virtual void **operator()**(*std*::ostream&) const = 0

inline virtual void **configure**(*std*::string const&)

Override this if you want to allow configuration through scripting.

That is, this allows configuration of your manipulator at run-time.

virtual **~manipulator**()

Protected Functions

manipulator() = default

Friends

inline friend void **format_value**(*std*::ostream &os, *std*::string_view, *manipulator* const &value)

pack_traversal

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/pack_traversal/pack_traversal_async.hpp

Defined in header hpx/pack_traversal/pack_traversal_async.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

Functions

template<typename **Visitor**, typename ...**T**>
auto **traverse_pack_async**(*Visitor* &&visitor, *T*&&... pack) -> decltype(detail::apply_pack_transform_async(*std*::forward<*Visitor*>(*visitor*), *std*::forward<*T*>(*pack*)...))

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus, we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```
struct my_async_visitor {
    // The synchronous overload is called for each object. It may
    // return false to suspend the current control. In that case the
    // overload below is called.
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    // The asynchronous overload is called when the synchronous
    // overload returned false. In addition to the current visited
    // element, the overload is called with a continuation callable
    // object which resumes the traversal when called later.
    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }

    // The overload is called when the traversal was finished. The
    // whole pack which was traversed asynchronously is passed.
    template <typename T>
    void operator()(async_traverse_complete_tag, T&& pack)
    {
    }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.

Parameters

- **`visitor`** – A visitor object which provides the three `operator()` overloads that were described above. Additionally, the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should have a virtual destructor!
- **`pack`** – The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.

Returns

A hpx::intrusive_ptr that references an instance of the given visitor object.

template<typename **`Allocator`**, typename **`Visitor`**, typename ...**T**>
auto **`traverse_pack_async_allocator`**(*Allocator* const &alloc, *Visitor* &&visitor, *T*&&... pack) -> decltype(detail::apply_pack_transform_async_allocator(*alloc*, *std*::forward<*Visitor*>(*visitor*), *std*::forward<*T*>(*pack*)...))

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus, we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```
struct my_async_visitor {
    // The synchronous overload is called for each object. It may
    // return false to suspend the current control. In that case the
    // overload below is called.
```

(continues on next page)

(continued from previous page)

```
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    // The asynchronous overload is called when the synchronous
    // overload returned false. In addition to the current visited
    // element, this overload receives a continuation callable object
    // which resumes the traversal when called later. The continuation
    // may be stored and called later or dropped completely to abort
    // the traversal early.
    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }

    // This overload is called when the traversal is finished. The
    // complete pack that was traversed asynchronously is passed.
    template <typename T>
    void operator()(async_traverse_complete_tag, T&& pack)
    {
    }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.

Parameters

- **`visitor`** – A visitor object which provides the three `operator()` overloads that were described above. Additionally, the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should have a virtual destructor!
- **`pack`** – The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.
- **`alloc`** – Allocator instance to use to create the traversal frame.

Returns

A hpx::intrusive_ptr that references an instance of the given visitor object.

hpx/pack_traversal/pack_traversal.hpp

Defined in header hpx/pack_traversal/pack_traversal.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`util`**

Functions

template<typename Mapper, typename...
T> < unspecified > map_pack (Mapper &&mapper, T &&... pack)

Maps the pack with the given mapper.

This function tries to visit all plain elements which may be wrapped in:

- homogeneous containers (`std::vector`, `std::list`)
- heterogeneous containers (`hpx::tuple`, `std::pair`, `std::array`) and re-assembles the pack with the result of the mapper. Mapping from one type to a different one is supported.

Elements that aren't accepted by the mapper are routed through and preserved through the hierarchy.

```
// Maps all integers to floats
map_pack([](int value) {
    return float(value);
},
1, hpx::make_tuple(2, std::vector<int>{3, 4}), 5);
```

Throws
`std::exception` – like objects which are thrown by an invocation to the mapper.

Parameters
- **`mapper`** – A callable object, which accept an arbitrary type and maps it to another type or the same one.
- **`pack`** – An arbitrary variadic pack which may contain any type.

Returns
The mapped element or in case the pack contains multiple elements, the pack is wrapped into a `hpx::tuple`.

hpx::functional::unwrap

Defined in header hpx/unwrap.hpp[917].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

struct **unwrap_all**

A helper function object for functionally invoking *`hpx::unwrap_all`*. For more information please refer to its documentation.

---

[918] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

[919] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

hpx::unwrap

Defined in header hpx/unwrap.hpp[920].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::functional::unwrap*
- *hpx::functional::unwrap_n*
- *hpx::functional::unwrap_all*
- *hpx::unwrap_n*
- *hpx::unwrap_all*
- *hpx::unwrapping*
- *hpx::unwrapping_n*
- *hpx::unwrapping_all*

template<typename ...**Args**>
auto *hpx*::**unwrap**(*Args*&&... args) -> decltype(*util*::detail::unwrap_depth_impl<1U>(*std*::forward<*Args*>(*args*)...))

A helper function for retrieving the actual result of any *hpx::future* like type which is wrapped in an arbitrary way.

Unwraps the given pack of arguments, so that any *hpx::future* object is replaced by its future result type in the argument pack:

- `hpx::future<int>` -> `int`
- `hpx::future<std::vector<float>>` -> `std::vector<float>`
- `std::vector<future<float>>` -> `std::vector<float>`

The function is capable of unwrapping *hpx::future* like objects that are wrapped inside any container or tuple like type, see hpx::util::map_pack() for a detailed description about which surrounding types are supported. Non *hpx::future* like types are permitted as arguments and passed through.

```
hpx:unwrap(hpx::make_ready_future(0));

// Multiple arguments hpx::tuple<int, int> i2 =
    hpx:unwrap(hpx::make_ready_future(1),
               hpx::make_ready_future(2));
```

Note

This function unwraps the given arguments until the first traversed nested *hpx::future* which corresponds to an unwrapping depth of one. See *hpx::unwrap_n()* for a function which unwraps the given arguments to a particular depth or *hpx::unwrap_all()* that unwraps all future like objects recursively which are contained in the arguments.

---

[920] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

Parameters

`args` – the arguments that are unwrapped which may contain any arbitrary future or non-future type.

Throws

`std::exception` – like objects in case any of the given wrapped *hpx::future* objects were resolved through an exception. See hpx::future::get() for details.

Returns

Depending on the count of arguments this function returns a *hpx::tuple* containing the unwrapped arguments if multiple arguments are given. In case the function is called with a single argument, the argument is unwrapped and returned.

hpx::unwrap_n

Defined in header hpx/unwrap.hpp[921].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::functional::unwrap*
- *hpx::functional::unwrap_n*
- *hpx::functional::unwrap_all*
- *hpx::unwrap*
- *hpx::unwrap_all*
- *hpx::unwrapping*
- *hpx::unwrapping_n*
- *hpx::unwrapping_all*

template<*std*::size_t **Depth**, typename ...**Args**>
auto **hpx::unwrap_n**(*Args*&&... args) -> decltype(*util*::detail::unwrap_depth_impl<*Depth*>(*std*::forward<*Args*>(*args*)...))

An alternative version of *hpx::unwrap()*, which unwraps the given arguments to a certain depth of *hpx::future* like objects.

See unwrap for a detailed description.

Template Parameters

Depth – The count of *hpx::future* like objects which are unwrapped maximally.

---

[921] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

hpx::unwrap_all

Defined in header hpx/unwrap.hpp[922].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::functional::unwrap*
- *hpx::functional::unwrap_n*
- *hpx::functional::unwrap_all*
- *hpx::unwrap*
- *hpx::unwrap_n*

template<typename **T**>

---

[922] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

[923] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

auto *hpx*::**unwrapping**(*T* &&callable) -> decltype(*util*::detail::functional_unwrap_depth_impl<1U>(*std*::forward<*T*>(*callable*)))

Returns a callable object which unwraps its arguments upon invocation using the *hpx::unwrap()* function and then passes the result to the given callable object.

```
    return left + right;
});

int i1 = callable(hpx::make_ready_future(1),
                  hpx::make_ready_future(2));
```

See *hpx::unwrap()* for a detailed description.

Parameters

`callable` – the callable object which is called with the result of the corresponding unwrap function.

hpx::unwrapping_n

Defined in header hpx/unwrap.hpp[924].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::functional::unwrap*
- *hpx::functional::unwrap_n*
- *hpx::functional::unwrap_all*
- *hpx::unwrap*
- *hpx::unwrap_n*
- *hpx::unwrap_all*
- *hpx::unwrapping*
- *hpx::unwrapping_all*

template<*std*::size_t **Depth**, typename **T**>
auto *hpx*::**unwrapping_n**(*T* &&callable) -> decltype(*util*::detail::functional_unwrap_depth_impl<*Depth*>(*std*::forward<*T*>(*callable*)))

Returns a callable object which unwraps its arguments upon invocation using the *hpx::unwrap_n()* function and then passes the result to the given callable object.

See *hpx::unwrapping()* for a detailed description.

---

[924] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

hpx::unwrapping_all

Defined in header hpx/unwrap.hpp[925].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::functional::unwrap*
- *hpx::functional::unwrap_n*
- *hpx::functional::unwrap_all*
- *hpx::unwrap*
- *hpx::unwrap_n*
- *hpx::unwrap_all*
- *hpx::unwrapping*
- *hpx::unwrapping_n*

template<typename **T**>
auto *hpx*::**unwrapping_all**(*T* &&callable) -> decltype(*util*::detail::functional_unwrap_depth_impl<0U>(*std*::forward<*T*>(*callable*)))

Returns a callable object which unwraps its arguments upon invocation using the *hpx::unwrap_all()* function and then passes the result to the given callable object.

See *hpx::unwrapping()* for a detailed description.

preprocessor

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/preprocessor/nargs.hpp

Defined in header hpx/preprocessor/nargs.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_PP_NARGS(...)

Expands to the number of arguments passed in

Example Usage:

```
HPX_PP_NARGS(hpx, pp, nargs)
HPX_PP_NARGS(hpx, pp)
HPX_PP_NARGS(hpx)
```

Expands to:

---

[925] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/unwrap.hpp

```
3
2
1
```

Parameters

- `...` – The variadic number of arguments

hpx/preprocessor/expand.hpp

Defined in header hpx/preprocessor/expand.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_PP_EXPAND(X)

The HPX_PP_EXPAND macro performs a double macro-expansion on its argument.

This macro can be used to produce a delayed preprocessor expansion.

Example:

```
#define MACRO(a, b, c) (a)(b)(c)
#define ARGS() (1, 2, 3)

HPX_PP_EXPAND(MACRO ARGS()) // expands to (1)(2)(3)
```

Parameters

- **X** – Token to be expanded twice

hpx/preprocessor/stringize.hpp

Defined in header hpx/preprocessor/stringize.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_PP_STRINGIZE(X)

The *HPX_PP_STRINGIZE* macro stringizes its argument after it has been expanded.

The passed argument `X` will expand to `"X"`. Note that the stringizing operator (#) prevents arguments from expanding. This macro circumvents this shortcoming.

Parameters

- **X** – The text to be converted to a string literal

hpx/preprocessor/cat.hpp

Defined in header hpx/preprocessor/cat.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

`HPX_PP_CAT`(A, B)

Concatenates the tokens `A` and `B` into a single token. Evaluates to `AB`

Parameters

- **`A`** – First token
- **`B`** – Second token

hpx/preprocessor/strip_parens.hpp

Defined in header hpx/preprocessor/strip_parens.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

`HPX_PP_STRIP_PARENS`(X)

For any symbol `X`, this macro returns the same symbol from which potential outer parens have been removed. If no outer parens are found, this macros evaluates to `X` itself without error.

The original implementation of this macro is from Steven Watanbe as shown in http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976

```
HPX_PP_STRIP_PARENS(no_parens)
HPX_PP_STRIP_PARENS((with_parens))
```

Example Usage:

This produces the following output

```
no_parens
with_parens
```

Parameters

- **`X`** – Symbol to strip parens from

resiliency

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/resiliency/async_replay.hpp

Defined in header hpx/resiliency/async_replay.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resiliency**

namespace **experimental**

Functions

template<typename **Pred**, typename **F**, typename ...**Ts**>
hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*F*, *Ts*...>> **hpx_invoke**(*async_replay_validate_t*, *std*::size_t n, *Pred* &&pred, *F* &&f, *Ts*&&... ts)

ADL hook for async_replay_validate CPO.

Asynchronously launches *f*, validating results with *pred*. Repeats on error up to *n* times (aborts on abort_replay_exception).

The CPO tag is `async_replay_validate_t`.

Parameters

- **n** – Maximum number of retry attempts.
- **pred** – Predicate validating each invocation result.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns

future with the first valid result of *f*.

template<typename **F**, typename ...**Ts**>
hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*F*, *Ts*...>> **hpx_invoke**(*async_replay_t*, *std*::size_t n, *F* &&f, *Ts*&&... ts)

ADL hook for async_replay CPO.

Asynchronously launches *f*, repeating on error up to *n* times (aborts on abort_replay_exception).

The CPO tag is `async_replay_t`.

Parameters

- **n** – Maximum number of retry attempts.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns

future with the first successful result of *f*.

hpx/resiliency/async_replicate.hpp

Defined in header hpx/resiliency/async_replicate.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`resiliency`**

namespace **`experimental`**

Functions

template<typename **`Vote`**, typename **`Pred`**, typename **`F`**, typename ...**`Ts`**>
hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*F*, *Ts*...>> **`hpx_invoke`**(*async_replicate_vote_validate_t*, *std*::size_t n, *Vote* &&vote, *Pred* &&pred, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate_vote_validate CPO.

Asynchronously launches *f* exactly *n* times, validates results with *pred*, then runs valid results through *vote*.

The CPO tag is `async_replicate_vote_validate_t`.

Parameters

- **`n`** – Number of replicated invocations.
- **`vote`** – Voting function selecting among valid results.
- **`pred`** – Predicate validating each invocation result.
- **`f`** – Callable to invoke asynchronously.
- **`ts`** – Arguments forwarded to *f*.

Returns

future with the voted-upon result.

template<typename **`Vote`**, typename **`F`**, typename ...**`Ts`**>
hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*F*, *Ts*...>> **`hpx_invoke`**(*async_replicate_vote_t*, *std*::size_t n, *Vote* &&vote, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate_vote CPO.

Asynchronously launches *f* exactly *n* times, runs valid results through *vote*. Validation uses the default exception check.

The CPO tag is `async_replicate_vote_t`.

Parameters

- **`n`** – Number of replicated invocations.
- **`vote`** – Voting function selecting among valid results.
- **`f`** – Callable to invoke asynchronously.
- **`ts`** – Arguments forwarded to *f*.

Returns

future with the voted-upon result.

template<typename **Pred**, typename **F**, typename ...**Ts**>
hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*F*, *Ts*...>> **hpx_invoke**(*async_replicate_validate_t*, *std*::size_t n, *Pred* &&pred, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate_validate CPO.

Asynchronously launches *f* exactly *n* times, validates results with *pred*. Returns the first valid result.

The CPO tag is `async_replicate_validate_t`.

Parameters
- **n** – Number of replicated invocations.
- **pred** – Predicate validating each invocation result.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns
future with the first valid result.

template<typename **F**, typename ...**Ts**>
hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*F*, *Ts*...>> **hpx_invoke**(*async_replicate_t*, *std*::size_t n, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate CPO.

Asynchronously launches *f* exactly *n* times. Validates by checking for exceptions. Returns the first valid result.

The CPO tag is `async_replicate_t`.

Parameters
- **n** – Number of replicated invocations.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns
future with the first non-throwing result.

decltype(auto) **hpx_invoke**(*async_replay_validate_t*, *Executor* &&exec, *std*::size_t n, *Pred* &&pred, *F* &&f, *Ts*&&... ts)

ADL hook for async_replay_validate CPO with executor.

Asynchronously launches *f* on *exec*, validating results with *pred*. Repeats on error up to *n* times (aborts on abort_replay_exception).

The CPO tag is `async_replay_validate_t`.

Parameters

- **exec** – Executor to run *f* on.
- **n** – Maximum number of retry attempts.
- **pred** – Predicate validating each invocation result.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns

future with the first valid result of *f*.

template<typename **Executor**, typename **F**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replay_t*, *Executor* &&exec, *std*::size_t n, *F* &&f, *Ts*&&... ts)

ADL hook for async_replay CPO with executor.

Asynchronously launches *f* on *exec*, repeating on error up to *n* times (aborts on abort_replay_exception).

The CPO tag is `async_replay_t`.

Parameters

- **exec** – Executor to run *f* on.
- **n** – Maximum number of retry attempts.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns

future with the first successful result of *f*.

hpx/resiliency/async_replicate_executor.hpp

Defined in header hpx/resiliency/async_replicate_executor.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resiliency**

namespace **experimental**

Functions

template<typename **Executor**, typename **Vote**, typename **Pred**, typename **F**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replicate_vote_validate_t*, *Executor* &&exec, *std*::size_t n, *Vote* &&vote, *Pred* &&pred, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate_vote_validate CPO with executor.

Asynchronously launches *f* exactly *n* times on *exec*, validates results with *pred*, then runs valid results through *vote*.

The CPO tag is `async_replicate_vote_validate_t`.

Parameters

- **exec** – Executor to run *f* on.
- **n** – Number of replicated invocations.
- **vote** – Voting function selecting among valid results.
- **pred** – Predicate validating each invocation result.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns

future with the voted-upon result.

template<typename **Executor**, typename **Vote**, typename **F**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replicate_vote_t*, *Executor* &&exec, *std*::size_t n, *Vote* &&vote, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate_vote CPO with executor.

Asynchronously launches *f* exactly *n* times on *exec*, runs valid results through *vote*. Validation uses the default exception check.

The CPO tag is `async_replicate_vote_t`.

Parameters

- **exec** – Executor to run *f* on.
- **n** – Number of replicated invocations.
- **vote** – Voting function selecting among valid results.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns

future with the voted-upon result.

template<typename **Executor**, typename **Pred**, typename **F**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replicate_validate_t*, *Executor* &&exec, *std*::size_t n, *Pred* &&pred, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate_validate CPO with executor.

Asynchronously launches *f* exactly *n* times on *exec*, validates results with *pred*. Returns the first valid result.

The CPO tag is `async_replicate_validate_t`.

Parameters

- **exec** – Executor to run *f* on.
- **n** – Number of replicated invocations.
- **pred** – Predicate validating each invocation result.
- **f** – Callable to invoke asynchronously.
- **ts** – Arguments forwarded to *f*.

Returns

future with the first valid result.

template<typename **Executor**, typename **F**, typename ...**Ts**>

decltype(auto) **`hpx_invoke`**(*async_replicate_t*, *Executor* &&exec, *std*::size_t n, *F* &&f, *Ts*&&... ts)

ADL hook for async_replicate CPO with executor.

Asynchronously launches *f* exactly *n* times on *exec*. Validates by checking for exceptions. Returns the first valid result.

The CPO tag is `async_replicate_t`.

Parameters

- **`exec`** – Executor to run *f* on.
- **`n`** – Number of replicated invocations.
- **`f`** – Callable to invoke asynchronously.
- **`ts`** – Arguments forwarded to *f*.

Returns

future with the first non-throwing result.

runtime_configuration

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/runtime_configuration/component_registry_base.hpp

Defined in header hpx/runtime_configuration/component_registry_base.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

struct **component_registry_base**

#include <component_registry_base.hpp> The component_registry_base has to be used as a base class for all component registries.

Public Functions

virtual **`~component_registry_base`**`()` = default

virtual bool **`get_component_info`**`(`*std*::vector<*std*::string> &fillini, *std*::string const &filepath, bool is_static = false`)` = 0

Return the ini-information for all contained components.

Parameters

- **`fillini`** – [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.
- **`filepath`** – [in]
- **`is_static`** – [in]

Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

virtual void **`register_component_type`**`()` = 0

Register the component type represented by this component.

hpx/runtime_configuration/plugin_registry_base.hpp

Defined in header hpx/runtime_configuration/plugin_registry_base.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`plugins`**

struct **`plugin_registry_base`**

#include <plugin_registry_base.hpp> The plugin_registry_base has to be used as a base class for all plugin registries.

Public Functions

virtual **`~plugin_registry_base`**`()` = default

virtual bool **`get_plugin_info`**`(`*std*::vector<*std*::string> &fillini`)` = 0

Return the configuration information for any plugin implemented by this module

Parameters

`fillini` – [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all plugins implemented in this module.

Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

inline virtual void **`init`**`(`int*, char***, *util*::*runtime_configuration*&`)`

hpx::runtime_mode

Defined in header hpx/init.hpp[926].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

enum class *hpx*::**runtime_mode** : *std*::int8_t

A HPX runtime can be executed in two different modes: console mode and worker mode.

Values:

enumerator **invalid**

enumerator **console**

The runtime is the console locality.

enumerator **worker**

The runtime is a worker locality.

enumerator **connect**

The runtime is a worker locality connecting late

enumerator **local**

The runtime is fully local.

enumerator **default_**

The runtime mode will be determined based on the command line arguments

enumerator **last**

hpx/runtime_configuration/runtime_configuration.hpp

Defined in header hpx/runtime_configuration/runtime_configuration.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

class **runtime_configuration** : public section

bool **tolerate_node_faults**()

Check whether fault tolerance for node/locality faults is enabled via the "enable_fault_tolerance" configuration entry in the "hpx" section.

Returns

true if fault tolerance is enabled, false otherwise.

inline void **tolerate_node_faults**(bool const value) const

Set whether this runtime instance should tolerate node faults.

This controls whether the runtime is configured to continue operating in the presence of locality failures (e.g. forced or unexpected disconnection of remote localities) rather than treating such failures as fatal errors.

Parameters

value – Set to `true` to enable fault tolerance for node failures, or `false` to require all localities to remain connected for normal operation.

hpx::components::component_commandline_base

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **`component_commandline_base`**

The component_commandline_base has to be used as a base class for all component command-line line handling registries.

Subclassed by hpx::components::component_commandline

HPX_REGISTER_COMPONENT_MODULE

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

`HPX_REGISTER_COMPONENT_MODULE()`

This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module. Ungated: a component may live in a shared library, in a statically linked build, or directly in the application executable.

runtime_local

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::register_thread

Defined in header hpx/runtime.hpp[927].

bool *hpx*::**register_thread**(*runtime* *rt, char const *name, *error_code* &ec = *throws*)

Register the current kernel thread with HPX, this should be done once for each external OS-thread intended to invoke HPX functionality. Calling this function more than once will return false.

hpx::unregister_thread

Defined in header hpx/runtime.hpp[928].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*

- *hpx::get_system_uptime*

runtime_local::os_thread_data `hpx::get_os_thread_data`(*std*::string const &label)

Access data for a given OS thread that was previously registered by *register_thread*. This function must be called from a thread that was previously registered with the runtime.

hpx::enumerate_os_threads

Defined in header hpx/runtime.hpp[930].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*
- *hpx::unregister_thread*

- *hpx::get_num_worker_threads*
- *hpx::get_system_uptime*

bool `hpx::enumerate_os_threads`(*hpx*::*function*<bool(os_thread_data const&)> const &f)

Enumerate all OS threads that have registered with the runtime.

hpx::get_runtime_instance_number

Defined in header hpx/runtime.hpp[931].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*
- *hpx::unregister_thread*
- *hpx::get_os_thread_data*
- *hpx::enumerate_os_threads*

- *hpx::get_system_uptime*

std::size_t `hpx::get_runtime_instance_number()`

Return the runtime instance number associated with the runtime instance the current thread is running in.

hpx::register_on_exit

Defined in header hpx/runtime.hpp[932].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*

- *hpx::get_num_worker_threads*
- *hpx::get_system_uptime*

bool `hpx::`**`is_starting`**`()`

Test whether the runtime system is currently being started.

This function returns whether the runtime system is currently being started or not, e.g. whether the current state of the runtime system is *hpx::state::startup*

Note

This function needs to be executed on a HPX-thread. It will return false otherwise.

hpx::tolerate_node_faults

Defined in header hpx/runtime.hpp[934].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*
- *hpx::unregister_thread*

- *hpx::get_num_worker_threads*
- *hpx::get_system_uptime*

bool *hpx*::**is_running**()

Test whether the runtime system is currently running.

This function returns whether the runtime system is currently running or not, e.g. whether the current state of the runtime system is *hpx::state::running*

Note

This function needs to be executed on a HPX-thread. It will return false otherwise.

---

[935] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

hpx::is_stopped

Defined in header hpx/runtime.hpp[936].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*
- *hpx::unregister_thread*

- *hpx::get_num_worker_threads*
- *hpx::get_system_uptime*

bool `hpx::is_stopped()`

Test whether the runtime system is currently stopped.

This function returns whether the runtime system is currently stopped or not, e.g. whether the current state of the runtime system is *hpx::state::stopped*

Note

This function needs to be executed on a HPX-thread. It will return false otherwise.

hpx::is_stopped_or_shutting_down

Defined in header hpx/runtime.hpp[937].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

- *hpx::tolerate_node_faults*
- *hpx::is_running*
- *hpx::is_stopped*
- *hpx::get_num_worker_threads*
- *hpx::get_system_uptime*

bool *hpx*::**is_stopped_or_shutting_down**()

Test whether the runtime system is currently being shut down.

This function returns whether the runtime system is currently being shut down or not, e.g. whether the current state of the runtime system is *hpx::state::stopped* or *hpx::state::shutdown*

Note

This function needs to be executed on a HPX-thread. It will return false otherwise.

hpx::get_num_worker_threads

Defined in header hpx/runtime.hpp[938].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*
- *hpx::unregister_thread*

- *hpx::is_stopped*
- *hpx::is_stopped_or_shutting_down*
- *hpx::get_system_uptime*

std::size_t *hpx*::**get_num_worker_threads**()

Return the number of worker OS- threads used to execute HPX threads.

This function returns the number of OS-threads used to execute HPX threads. If the function is called while no HPX runtime system is active, it will return zero.

---

[938] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

hpx::get_system_uptime

Defined in header hpx/runtime.hpp[939].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_thread*
- *hpx::unregister_thread*

- *hpx::is_stopped_or_shutting_down*
- *hpx::get_num_worker_threads*

std::uint64_t *hpx*::**get_system_uptime**()

Return the system uptime measure on the thread executing this call.

This function returns the system uptime measured in nanoseconds for the thread executing this call. If the function is called while no HPX runtime system is active, it will return zero.

hpx/runtime_local/get_worker_thread_num.hpp

Defined in header hpx/runtime_local/get_worker_thread_num.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::startup_function_type

Defined in header hpx/runtime.hpp[940].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_pre_startup_function*
- *hpx::register_startup_function*

using *hpx*::**startup_function_type** = *hpx*::*move_only_function*<void()>

The type of the function which is registered to be executed as a startup or pre-startup function.

---

[939] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

[940] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

hpx::register_pre_startup_function

Defined in header hpx/runtime.hpp[941].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::startup_function_type*
- *hpx::register_startup_function*

void `hpx::register_pre_startup_function`(*startup_function_type* f)

Add a function to be executed by a HPX thread before hpx_main but guaranteed before any startup function is executed (system-wide).

Any of the functions registered with *register_pre_startup_function* are guaranteed to be executed by an HPX thread before any of the registered startup functions are executed (see hpx::register_startup_function()).

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

See also

hpx::register_startup_function()

Note

If this function is called while the pre-startup functions are being executed or after that point, it will raise aninvalid_status exception.

Parameters

`f` – [in] The function to be registered to run by an HPX thread as a pre-startup function.

hpx::register_startup_function

Defined in header hpx/runtime.hpp[942].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::startup_function_type*
- *hpx::register_pre_startup_function*

---

[941] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

[942] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

void *hpx*::**`register_startup_function`**(*startup_function_type* f)

Add a function to be executed by a HPX thread before hpx_main but guaranteed after any pre-startup function is executed (system-wide).

Any of the functions registered with *register_startup_function* are guaranteed to be executed by an HPX thread after any of the registered pre-startup functions are executed (see: hpx::register_pre_startup_function()), but before *hpx_main* is being called.

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

See also

hpx::register_pre_startup_function()

Note

If this function is called while the startup functions are being executed or after that point, it will raise an invalid_status exception.

Parameters

`f` – [in] The function to be registered to run by an HPX thread as a startup function.

hpx/runtime_local/service_executors.hpp

Defined in header hpx/runtime_local/service_executors.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`execution`**

namespace **`experimental`**

Enums

enum class **`service_executor_type`** : *std*::uint8_t

Values:

enumerator **`io_thread_pool`**

Selects creating a service executor using the I/O pool of threads enumerator **`parcel_thread_pool`**

Selects creating a service executor using the parcel pool of threads

enumerator **`timer_thread_pool`**

Selects creating a service executor using the timer pool of threads

enumerator **`main_thread`**

Selects creating a service executor using the main thread

struct **`service_executor`** : public *parallel*::*execution*::detail::service_executor

Subclassed by *hpx::execution::experimental::io_pool_executor*, *hpx::execution::experimental::main_pool_executor*, *hpx::execution::experimental::parcel_pool_executor*, *hpx::execution::experimental::timer_pool_executor*

Public Functions

explicit **`service_executor`**(*service_executor_type* t, char const *name_suffix = "")

Constructs an executor for the selected service thread pool.

Parameters

- **`t`** – The service thread pool to use.
- **`name_suffix`** – The suffix used to select a named pool.

struct **`io_pool_executor`** : public *hpx*::*execution*::*experimental*::*service_executor*

Public Functions

`io_pool_executor`()

struct **`parcel_pool_executor`** : public *hpx*::*execution*::*experimental*::*service_executor*

Public Functions

hpx/runtime_local/report_error.hpp

Defined in header hpx/runtime_local/report_error.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

void **report_error**(*std*::size_t num_thread, *std*::exception_ptr const &e)

The function report_error reports the given exception to the console.

void **report_error**(*std*::exception_ptr const &e)

The function report_error reports the given exception to the console.

hpx/runtime_local/runtime_local.hpp

Defined in header hpx/runtime_local/runtime_local.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

void **set_error_handlers**(*hpx*::*util*::*runtime_configuration* const &cfg)

class **runtime**

Public Types

using **notification_policy_type** = *threads*::*policies*::callback_notifier

Generate a new notification policy instance for the given thread name prefix

using **hpx_main_function_type** = int()

The *hpx_main_function_type* is the default function type usable as the main HPX thread function.

using **hpx_errorsink_function_type** = void(*std*::uint32_t, *std*::string const&)

Public Functions

virtual *notification_policy_type* **get_notification_policy**(char const *prefix, runtime_local::os_thread_type type)

state **get_state**() const

void **set_state**(state s)

explicit **runtime**(*hpx*::*util*::*runtime_configuration* rtcfg, bool initialize)

Construct a new HPX runtime instance.

virtual **~runtime**()

The destructor makes sure all HPX runtime services are properly shut down before exiting.

void **on_exit**(*hpx*::*function*<void()> const &f)

Manage list of functions to call on exit.

void **`starting`**()

Manage runtime 'stopped' state.

void **`stopping`**()

Call all registered on_exit functions.

bool **`stopped`**() const

This accessor returns whether the runtime instance has been stopped.

hpx::*util*::*runtime_configuration* &**`get_config`**()

access configuration information

hpx::*util*::*runtime_configuration* const &**`get_config`**() const

std::size_t **`get_instance_number`**() const

util::*thread_mapper* &**`get_thread_mapper`**() const

Return a reference to the internal PAPI thread manager.

threads::*topology* const &**`get_topology`**() const

virtual int **`run`**(*hpx*::*function*<*hpx_main_function_type*> const &func)

Run the HPX runtime system, use the given function for the main *thread* and block waiting for all threads to finish.

> **Note**
>
> The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

Parameters

`func` – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

virtual int **`run`**()

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

Returns

This function will always return 0 (zero).

virtual void **`rethrow_exception`**()

Rethrow any stored exception (to be called after *stop()*)

virtual int **`start`**(*hpx*::*function*<*hpx_main_function_type*> const &func, bool blocking = false)

Start the runtime system.

Parameters

- **`func`** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*.

- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function runtime::start will call runtime::wait internally.

Returns

If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise, it will return zero.

virtual int **start**(bool blocking = false)

Start the runtime system.

Parameters

blocking – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function runtime::start will call runtime::wait internally .

Returns

If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise, it will return zero.

virtual int **wait**()

Wait for the shutdown action to be executed.

Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

virtual void **stop**(bool blocking = true)

Initiate termination of the runtime system.

Parameters

blocking – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

virtual int **suspend**()

Suspend the runtime system.

virtual int **resume**()

Resume the runtime system.

virtual int **finalize**(double)

virtual bool **is_networking_enabled**()

Return true if networking is enabled.

virtual *hpx*::*threads*::*threadmanager* &**get_thread_manager**()

Allow access to the thread manager instance used by the HPX runtime.

virtual *std*::string **here**() const

Returns a string of the locality endpoints (usable in debug output)

virtual bool **report_error**(*std*::size_t num_thread, *std*::exception_ptr const &e, bool terminate_all = true)

Report a non-recoverable error to the runtime system.

Parameters

- **num_thread** – [in] The number of the operating system thread the error has been detected in.
- **e** – [in] This is an instance encapsulating an exception which lead to this function call.

- **terminate_all** – [in] signal whether all localities should be terminated

virtual bool **report_error**(*std*::exception_ptr const &e, bool terminate_all = true)

Report a non-recoverable error to the runtime system.

> **Note**
>
> This function will retrieve the number of the current shepherd thread and forward to the report_error function above.

Parameters

- **e** – [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate_all** – [in] signal whether all localities should be terminated

virtual void **add_pre_startup_function**(*startup_function_type* f)

Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with *add_startup_function*.

> **Note**
>
> The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

Parameters

f – The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to set up the runtime environment of the application (install performance counters, etc.)

virtual void **add_startup_function**(*startup_function_type* f)

Add a function to be executed inside a HPX thread before hpx_main

Parameters

f – The function 'f' will be called from inside a HPX thread before hpx_main is executed. This is very useful to set up the runtime environment of the application (install performance counters, etc.)

virtual void **add_pre_shutdown_function**(*shutdown_function_type* f)

Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

> **Note**
>
> The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

Parameters

f – The function 'f' will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

virtual void **add_shutdown_function**(*shutdown_function_type* f)

Add a function to be executed inside a HPX thread during hpx::finalize

Parameters

f – The function 'f' will be called from inside a HPX thread while hpx::finalize is executed.

This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

virtual *hpx*::*util*::*io_service_pool* ***get_thread_pool**(char const *name)

Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks. The three possible values for the argument `name` are "main_pool", "io_pool", "parcel_pool", and "timer_pool". For any other argument value the function will return zero.

virtual bool **register_thread**(char const *name, *std*::size_t num = 0, bool service_thread = true, *error_code* &ec = *throws*)

Register an external OS-thread with HPX.

This function should be called from any OS-thread which is external to HPX (not created by HPX), but which needs to access HPX functionality, such as setting a value on a promise or similar.

'main', 'io', 'timer', 'parcel', 'worker'

> **Note**
>
> The function will compose a thread name from `name` and `num` which is used to register the thread. It is the user's responsibility to ensure that each (composed) thread name is unique. HPX internally uses the following names for the threads it creates, do not reuse those:

> **Note**
>
> This function should be called for each thread exactly once. It will fail if it is called more than once.

Parameters

- **name** – [in] The name to use for thread registration.
- **num** – [in] The sequence number to use for thread registration. The default for this parameter is zero.
- **service_thread** – [in] The thread should be registered as a service thread. The default for this parameter is 'true'. Any service threads will be pinned to cores not currently used by any of the HPX worker threads.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will return whether the requested operation succeeded or not.

virtual bool **unregister_thread**()

Unregister an external OS-thread with HPX.

This function will unregister any external OS-thread from HPX.

> **Note**
>
> This function should be called for each thread exactly once. It will fail if it is called more than once. It will fail as well if the thread has not been registered before (see *register_thread*).

Returns

This function will return whether the requested operation succeeded or not.

virtual runtime_local::os_thread_data **get_os_thread_data**(*std*::string const &label) const

Access data for a given OS thread that was previously registered by *register_thread*.

virtual bool **enumerate_os_threads**(*hpx*::*function*<bool(runtime_local::os_thread_data const&)> const &f) const

Enumerate all OS threads that have registered with the runtime.

Protected Static Attributes

static *std*::atomic<int> **instance_number_counter_**

Private Functions

void **stop_helper**(bool blocking, *std*::condition_variable &cond, *std*::mutex &mtx) const

Helper function to stop the runtime.

Parameters

- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.
- **cond** –
- **mtx** –

void **deinit_tss_helper**(char const *context, *std*::size_t num) const

void **init_tss_ex**(char const *context, runtime_local::os_thread_type type, *std*::size_t local_thread_num, *std*::size_t global_thread_num, char const *pool_name, char const *postfix, bool service_thread, *error_code* &ec) const

void **init_tss_helper**(char const *context, runtime_local::os_thread_type type, *std*::size_t local_thread_num, *std*::size_t global_thread_num, char const *pool_name, char const *postfix, bool service_thread) const

hpx::program_options::options_description **`app_options_`**

namespace **`threads`**

Functions

char const ***`get_stack_size_name`**(*std*::ptrdiff_t size)

Returns the stack size name.

Get the readable string representing the given stack size constant.

Parameters

`size` – this represents the stack size

std::ptrdiff_t **`get_default_stack_size`**()

Returns the default stack size.

Get the default stack size in bytes.

std::ptrdiff_t **`get_stack_size`**(*thread_stacksize* size)

Returns the stack size corresponding to the given stack size enumeration.

Get the stack size corresponding to the given stack size enumeration.

Parameters

`size` – this represents the stack size

namespace **`util`**

Functions

bool **retrieve_commandline_arguments**(*hpx*::program_options::options_description const &app_options, *hpx*::program_options::variables_map &vm)

bool **retrieve_commandline_arguments**(*std*::string const &app_name, *hpx*::program_options::variables_map &vm)

hpx::shutdown_function_type

Defined in header hpx/runtime.hpp[943].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::register_pre_shutdown_function*
- *hpx::register_shutdown_function*

using *hpx*::**shutdown_function_type** = *hpx*::*move_only_function*<void()>

The type of the function which is registered to be executed as a shutdown or pre-shutdown function.

hpx::register_pre_shutdown_function

Defined in header hpx/runtime.hpp[944].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::shutdown_function_type*
- *hpx::register_shutdown_function*

void *hpx*::**register_pre_shutdown_function**(*shutdown_function_type* f)

Add a function to be executed by a HPX thread during hpx::finalize() but guaranteed before any shutdown function is executed (system-wide)

Any of the functions registered with *register_pre_shutdown_function* are guaranteed to be executed by an HPX thread during the execution of hpx::finalize() before any of the registered shutdown functions are executed (see: hpx::register_shutdown_function()).

See also

hpx::register_shutdown_function()

Note

If this function is called while the pre-shutdown functions are being executed, or after that point, it will raise an invalid_status exception.

Parameters

`f` – [in] The function to be registered to run by an HPX thread as a pre-shutdown function.

hpx::register_shutdown_function

Defined in header hpx/runtime.hpp[945].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::shutdown_function_type*
- *hpx::register_pre_shutdown_function*

void `hpx::register_shutdown_function`(*shutdown_function_type* f)

Add a function to be executed by a HPX thread during hpx::finalize() but guaranteed after any pre-shutdown function is executed (system-wide)

Any of the functions registered with *register_shutdown_function* are guaranteed to be executed by an HPX thread during the execution of hpx::finalize() after any of the registered pre-shutdown functions are executed (see: hpx::register_pre_shutdown_function()).

See also

hpx::register_pre_shutdown_function()

Note

If this function is called while the shutdown functions are being executed, or after that point, it will raise an invalid_status exception.

Parameters

`f` – [in] The function to be registered to run by an HPX thread as a shutdown function.

---

[945] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

hpx/runtime_local/thread_pool_helpers.hpp

Defined in header hpx/runtime_local/thread_pool_helpers.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resource**

Functions

std::size_t **get_num_thread_pools**()

Return the number of thread pools currently managed by the *resource_partitioner*

std::size_t **get_num_threads**()

Return the number of threads in all thread pools currently managed by the *resource_partitioner*

std::size_t **get_num_threads**(*std*::string const &pool_name)

Return the number of threads in the given thread pool currently managed by the *resource_partitioner*

std::size_t **get_num_threads**(*std*::size_t pool_index)

Return the number of threads in the given thread pool currently managed by the *resource_partitioner*

std::size_t **get_pool_index**(*std*::string const &pool_name)

Return the internal index of the pool given its name.

std::string const &**get_pool_name**(*std*::size_t pool_index)

Return the name of the pool given its internal index.

threads::*thread_pool_base* &**get_thread_pool**(*std*::string const &pool_name)

Return the name of the pool given its name.

threads::*thread_pool_base* &**get_thread_pool**(*std*::size_t pool_index)

Return the thread pool given its internal index.

bool **pool_exists**(*std*::string const &pool_name)

Return true if the pool with the given name exists.

bool **pool_exists**(*std*::size_t pool_index)

Return true if the pool with the given index exists.

namespace **threads**

Functions

std::int64_t **get_thread_count**(*thread_schedule_state* state = *thread_schedule_state*::*unknown*)

The function *get_thread_count* returns the number of currently known threads.

> **Note**
>
> If state == unknown this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

Parameters

`state` – [in] This specifies the thread-state for which the number of threads should be retrieved.

std::int64_t **`get_thread_count`**(*thread_priority* priority, *thread_schedule_state* state = *thread_schedule_state*::*unknown*)

The function *get_thread_count* returns the number of currently known threads.

> **Note**
>
> If state == unknown this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

Parameters

- **`priority`** – [in] This specifies the thread-priority for which the number of threads should be retrieved.
- **`state`** – [in] This specifies the thread-state for which the number of threads should be retrieved.

std::int64_t **`get_idle_core_count`**()

The function *get_idle_core_count* returns the number of currently idling threads (cores).

mask_type **`get_idle_core_mask`**()

The function *get_idle_core_mask* returns a bit-mask representing the currently idling threads (cores).

bool **`enumerate_threads`**(*hpx*::*function*<bool(thread_id_type)> const &f, *thread_schedule_state* state = *thread_schedule_state*::*unknown*)

The function *enumerate_threads* will invoke the given function *f* for each thread with a matching thread state.

Parameters

- **`f`** – [in] The function which should be called for each matching thread. Returning 'false' from this function will stop the enumeration process.
- **`state`** – [in] This specifies the thread-state for which the threads should be enumerated.

hpx::get_initial_num_localities

Defined in header hpx/runtime.hpp[946].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::get_num_localities*

---

[946] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

std::uint32_t *hpx*::**get_initial_num_localities**()

Return the number of localities which were registered at startup for the running application.

The function *get_initial_num_localities* returns the number of localities which were connected to the console at application startup.

See also

hpx::find_all_localities, hpx::get_num_localities

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

hpx::get_num_localities

Defined in header hpx/runtime.hpp[947].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::get_initial_num_localities*

hpx::*future*<*std*::uint32_t> *hpx*::**get_num_localities**()

Asynchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* asynchronously returns the number of localities currently connected to the console. The returned future represents the actual result.

See also

hpx::find_all_localities, hpx::get_num_localities

Note

This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

std::uint32_t *hpx*::**get_num_localities**(*launch*::sync_policy, *error_code* &ec = *throws*)

Return the number of localities which are currently registered for the running application.

The function *get_num_localities* returns the number of localities currently connected to the console.

---

[947] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

See also

hpx::find_all_localities, hpx::get_num_localities

Note

This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<*std*::uint32_t> `hpx::get_num_localities`(*components*::*component_type* t)

Asynchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* asynchronously returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

See also

hpx::find_all_localities, hpx::get_num_localities

Note

This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Parameters

`t` – The component type for which the number of connected localities should be retrieved.

std::uint32_t `hpx::get_num_localities`(*launch*::sync_policy, *components*::*component_type* t, *error_code* &ec = *throws*)

Synchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

See also

hpx::find_all_localities, hpx::get_num_localities

> **Note**
>
> This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Parameters

- `t` – The component type for which the number of connected localities should be retrieved.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::get_locality_id

Defined in header hpx/runtime.hpp[948].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

std::uint32_t `hpx::get_locality_id`(*error_code* &ec = *throws*)

Return the number of the locality this function is being called from.

This function returns the id of the current locality.

> **Note**
>
> The returned value is zero based and its maximum value is smaller than the overall number of localities the current application is running on (as returned by get_num_localities()).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

> **Note**
>
> This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

---

[948] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

hpx::get_locality_name

Defined in header hpx/runtime.hpp[949].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

std::string *hpx*::**get_locality_name**()

Return the name of the locality this function is called on.

This function returns the name for the locality on which this function is called.

See also

future<std::string> get_locality_name(hpx::id_type const& id)

Returns

This function returns the name for the locality on which the function is called. The name is retrieved from the underlying networking layer and may be different for different parcelports.

future<*std*::string> *hpx*::**get_locality_name**(*hpx*::*id_type* const &id)

Return the name of the referenced locality.

This function returns a future referring to the name for the locality of the given id.

See also

std::string get_locality_name()

Parameters

id – [in] The global id of the locality for which the name should be retrieved

Returns

This function returns the name for the locality of the given id. The name is retrieved from the underlying networking layer and may be different for different parcel ports.

hpx/runtime_local/thread_hooks.hpp

Defined in header hpx/runtime_local/thread_hooks.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

---

[949] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

Functions

threads::*policies*::callback_notifier::on_startstop_type **`get_thread_on_start_func`**`()`

Retrieve the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *register_thread_on_start_func*).

Note

This function can be called before the HPX runtime is initialized.

Returns

The currently installed error handler function.

threads::*policies*::callback_notifier::on_startstop_type **`get_thread_on_stop_func`**`()`

Retrieve the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see *register_thread_on_stop_func*).

Note

This function can be called before the HPX runtime is initialized.

Returns

The currently installed error handler function.

threads::*policies*::callback_notifier::on_error_type **`get_thread_on_error_func`**`()`

Retrieve the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see *register_thread_on_error_func*).

Note

This function can be called before the HPX runtime is initialized.

Returns

The currently installed error handler function.

threads::*policies*::callback_notifier::on_startstop_type **`register_thread_on_start_func`**`(`*threads*::*policies*::callback_notifier:
&&f`)`

Set the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see *get_thread_on_start_func*).

Note

This function can be called before the HPX runtime is initialized.

Parameters

f – The function to install as the new start handler.

Returns

The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

threads::*policies*::callback_notifier::on_startstop_type **register_thread_on_stop_func**(*threads*::*policies*::callback_notifier::o
&&f)

Set the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see *get_thread_on_stop_func*).

Note

This function can be called before the HPX runtime is initialized.

Parameters

f – The function to install as the new stop handler.

Returns

The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

threads::*policies*::callback_notifier::on_error_type **register_thread_on_error_func**(*threads*::*policies*::callback_notifier::on
&&f)

Set the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see *get_thread_on_error_func*).

Note

This function can be called before the HPX runtime is initialized.

Parameters

f – The function to install as the new error handler.

Returns

The previously registered function of this category. It is the user's responsibility to call that function if the callback is invoked by HPX.

hpx/runtime_local/component_startup_shutdown_base.hpp

Defined in header hpx/runtime_local/component_startup_shutdown_base.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`components`**

struct **`component_startup_shutdown_base`**

#include <component_startup_shutdown_base.hpp> The component_startup_shutdown_base has to be used as a base class for all component startup/shutdown registries.

Public Functions

virtual **`~component_startup_shutdown_base`**`()` = default

virtual bool **`get_startup_function`**`(`*startup_function_type* &startup, bool &pre_startup`)` = 0

Return any startup function for this component.

Parameters

- **`startup`** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.
- **`pre_startup`** – [in, out] Will be set to true if the returned startup function is executed during the first round of calls.

Returns

Returns *true* if the parameter *startup* has been successfully initialized with the startup function.

virtual bool **`get_shutdown_function`**`(`*shutdown_function_type* &shutdown, bool &pre_shutdown`)` = 0

Return any startup function for this component.

Parameters

- **`shutdown`** – [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.
- **`pre_shutdown`** – [in, out] Will be set to true if the returned shutdown function is executed during the first round of calls.

Returns

Returns *true* if the parameter *shutdown* has been successfully initialized with the shutdown function.

hpx/runtime_local/termination_detection.hpp

Defined in header hpx/runtime_local/termination_detection.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **local**

Functions

void **termination_detection**()

Wait for all local HPX threads to complete execution.

This function blocks the calling thread until all HPX worker threads on the current locality have completed their work and become idle. It performs local termination detection by waiting for the thread manager to drain all pending tasks.

Example:

```
#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>

int hpx_main()
{
    // Launch some asynchronous work
    for (int i = 0; i < 100; ++i)
    {
        hpx::post([]{ /* do work */ });
    }

    // Wait for all local threads to complete
    hpx::local::termination_detection();

    return hpx::finalize();
}
```

> **Note**
>
> This function should be called from an HPX thread or after the HPX runtime has been initialized.

Throws

`hpx::exception` – if called when the runtime is not in a valid state (e.g., before initialization or after shutdown).

bool **termination_detection**(*hpx*::chrono::*steady_duration* const &timeout)

Wait for all local HPX threads to complete with a timeout.

This function blocks the calling thread until either all HPX worker threads have completed their work, or the specified timeout duration has elapsed.

See also

termination_detection()

Example:

```
#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>
#include <chrono>

int hpx_main()
{
    // Launch some work
    hpx::post([]{ /* long running task */ });

    // Wait up to 5 seconds
    if (!hpx::local::termination_detection(std::chrono::seconds(5)))
    {
        std::cerr << "Warning: Work did not complete within timeout\n";
        // Implement fallback strategy
    }

    return hpx::finalize();
}
```

Parameters

`timeout` – Maximum duration to wait for termination. The function will return false if this duration elapses before all threads complete.

Throws

hpx::*exception* – if called when the runtime is not in a valid state.

Returns

true if all threads completed before the timeout, false if the timeout elapsed.

bool **`termination_detection`**(*hpx*::chrono::*steady_time_point* const &deadline)

Wait for all local HPX threads to complete until a deadline.

This function blocks the calling thread until either all HPX worker threads have completed their work, or the specified deadline time point is reached.

See also

termination_detection(std::chrono::duration<double>)

Example:

```
#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>
#include <chrono>

int hpx_main()
{
    auto deadline = std::chrono::steady_clock::now() +
```

(continues on next page)

(continued from previous page)

```
                    std::chrono::seconds(10);

    hpx::post([]{ /* work */ });

    if (!hpx::local::termination_detection(deadline))
    {
        std::cerr << "Deadline reached\n";
    }

    return hpx::finalize();
}
```

Parameters

`deadline` – Absolute time point when waiting should stop. The function will return false if this time is reached before all threads complete.

Throws

hpx::*exception* – if called when the runtime is not in a valid state.

Returns

true if all threads completed before the deadline, false if the deadline was reached.

bool **termination_detection**(*hpx*::*stop_token* stop_token, *hpx*::chrono::*steady_duration* const &timeout = *hpx*::chrono::*steady_duration*((*hpx*::chrono::steady_clock::duration::max)()))

Wait for all local HPX threads with cancellation support.

This function blocks the calling thread until all HPX worker threads have completed, the timeout elapses, or a stop is requested via the stop_token. This enables cooperative cancellation of the wait operation.

See also

termination_detection(std::chrono::duration<double>)

Example:

```
#include <hpx/hpx_init.hpp>
#include <hpx/runtime_local/termination_detection.hpp>
#include <hpx/stop_token.hpp>
#include <chrono>

int hpx_main()
{
    hpx::stop_source stop_src;

    // In shutdown handler
    hpx::thread shutdown_thread([&stop_src]() {
        hpx::this_thread::sleep_for(std::chrono::seconds(30));
        stop_src.request_stop();
    });

    hpx::post([]{ /* work */ });
```

(continues on next page)

(continued from previous page)

```
    // Wait with cancellation support
    bool completed = hpx::local::termination_detection(
        stop_src.get_token(),
        std::chrono::minutes(1)
    );

    if (!completed)
    {
        std::cerr << "Cancelled or timed out\n";
    }

    shutdown_thread.join();
    return hpx::finalize();
}
```

Parameters

- **`stop_token`** – Token that can be used to request cancellation of the wait operation.
- **`timeout`** – Maximum duration to wait. Defaults to maximum duration (effectively infinite).

Throws

`hpx``::`*`exception`* – if called when the runtime is not in a valid state.

Returns

true if all threads completed, false if timeout elapsed or stop was requested.

hpx/runtime_local/get_os_thread_count.hpp

Defined in header hpx/runtime_local/get_os_thread_count.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

Functions

std::size_t **`get_os_thread_count`**`()`

Return the number of OS-threads running in the runtime instance the current HPX-thread is associated with.

std::size_t **`get_os_thread_count`**`(`*threads*::executor const &exec`)`

Return the number of worker OS- threads used by the given executor to execute HPX threads.

This function returns the number of cores used to execute HPX threads for the given executor. If the function is called while no HPX runtime system is active, it will return zero. If the executor is not valid, this function will fall back to retrieving the number of OS threads used by HPX.

Parameters

`exec` – [in] The executor to be used.

namespace **`threads`**

hpx::get_thread_name

Defined in header hpx/runtime.hpp[950].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

std::string *hpx*::**get_thread_name**()

Return the name of the calling thread.

This function returns the name of the calling thread. This name uniquely identifies the thread in the context of HPX. If the function is called while no HPX runtime system is active, the result will be "<unknown>".

hpx/runtime_local/custom_exception_info.hpp

Defined in header hpx/runtime_local/custom_exception_info.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

std::string **diagnostic_information**(exception_info const &xi)

Extract the diagnostic information embedded in the given exception and return a string holding a formatted message.

The function *hpx::diagnostic_information* can be used to extract all diagnostic information stored in the given exception instance as a formatted string. This simplifies debug output as it composes the diagnostics into one, easy to use function call. This includes the name of the source file and line number, the sequence number of the OS-thread and the HPX-thread id, the locality id and the stack backtrace of the point where the original exception was thrown.

See also

hpx::get_error_locality_id(), *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

xi – The parameter `e` will be inspected for all diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`std::bad_alloc` – (if any of the required allocation operations fail)

Returns

The formatted string holding all the available diagnostic information stored in the given exception instance.

---

[950] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

std::string **`default_diagnostic_information`**(*std*::exception_ptr const &e)

std::uint32_t **`get_error_locality_id`**(*hpx*::exception_info const &xi) noexcept

Return the locality id where the exception was thrown.

The function *hpx::get_error_locality_id* can be used to extract the diagnostic information element representing the locality id as stored in the given exception instance.

See also

hpx::diagnostic_information(), *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`nothing` –

Returns

The locality id of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return *hpx::naming::invalid_locality_id*.

std::string **`get_error_host_name`**(*hpx*::exception_info const &xi)

Return the hostname of the locality where the exception was thrown.

The function *hpx::get_error_host_name* can be used to extract the diagnostic information element representing the host name as stored in the given exception instance.

See also

hpx::diagnostic_information() *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()* *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`std::bad_alloc` – (if one of the required allocations fails)

Returns

The hostname of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return and empty string.

std::int64_t **`get_error_process_id`**(*hpx*::exception_info const &xi) noexcept

Return the (operating system) process id of the locality where the exception was thrown.

The function *hpx::get_error_process_id* can be used to extract the diagnostic information element representing the process id as stored in the given exception instance.

See also

hpx::diagnostic_information(), *hpx::get_error_host_name()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`nothing` –

Returns

The process id of the OS-process which threw the exception If the exception instance does not hold this information, the function will return 0.

std::string **`get_error_env`**(*hpx*::exception_info const &xi)

Return the environment of the OS-process at the point the exception was thrown.

The function *hpx::get_error_env* can be used to extract the diagnostic information element representing the environment of the OS-process collected at the point the exception was thrown.

See also

hpx::diagnostic_information(), *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`std::bad_alloc` – (if one of the required allocations fails)

Returns

The environment from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

std::string **`get_error_backtrace`**(*hpx*::exception_info const &xi)

Return the stack backtrace from the point the exception was thrown.

The function *hpx::get_error_backtrace* can be used to extract the diagnostic information element representing the stack backtrace collected at the point the exception was thrown.

> **See also**
>
> *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`std::bad_alloc` – (if one of the required allocations fails)

Returns

The stack back trace from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

std::size_t **`get_error_os_thread`**(*hpx*::exception_info const &xi) noexcept

Return the sequence number of the OS-thread used to execute HPX-threads from which the exception was thrown.

The function *hpx::get_error_os_thread* can be used to extract the diagnostic information element representing the sequence number of the OS-thread as stored in the given exception instance.

> **See also**
>
> *hpx::diagnostic_information()*, *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_thread_id()*, *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`nothing` –

Returns

The sequence number of the OS-thread used to execute the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return std::size(-1).

std::size_t **`get_error_thread_id`**(*hpx*::exception_info const &xi) noexcept

Return the unique thread id of the HPX-thread from which the exception was thrown.

The function *hpx::get_error_thread_id* can be used to extract the diagnostic information element representing the HPX-thread id as stored in the given exception instance.

See also

hpx::diagnostic_information(), *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()* *hpx::get_error_thread_description()*, *hpx::get_error()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error_what()*, *hpx::get_error_config()*, *hpx::get_error_state()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`nothing` –

Returns

The unique thread id of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return std::size_t(0).

std::string **`get_error_thread_description`**(*hpx*::exception_info const &xi)

Return any additionally available thread description of the HPX-thread from which the exception was thrown.

The function *hpx::get_error_thread_description* can be used to extract the diagnostic information element representing the additional thread description as stored in the given exception instance.

See also

hpx::diagnostic_information(), *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error()*, *hpx::get_error_state()*, *hpx::get_error_what()*, *hpx::get_error_config()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`std::bad_alloc` – (if one of the required allocations fails)

Returns

Any additionally available thread description of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

std::string **`get_error_config`**(*hpx*::exception_info const &xi)

Return the HPX configuration information point from which the exception was thrown.

The function *hpx::get_error_config* can be used to extract the HPX configuration information element representing the full HPX configuration information as stored in the given exception instance.

See also

hpx::diagnostic_information(), *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error()*, *hpx::get_error_state()* *hpx::get_error_what()*, *hpx::get_error_thread_description()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`std::bad_alloc` – (if one of the required allocations fails)

Returns

Any additionally available HPX configuration information the point from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

std::string **`get_error_state`**(*hpx*::exception_info const &xi)

Return the HPX runtime state information at which the exception was thrown.

The function *hpx::get_error_state* can be used to extract the HPX runtime state information element representing the state the runtime system is currently in as stored in the given exception instance.

See also

hpx::diagnostic_information(), *hpx::get_error_host_name()*, *hpx::get_error_process_id()*, *hpx::get_error_function_name()*, *hpx::get_error_file_name()*, *hpx::get_error_line_number()*, *hpx::get_error_os_thread()*, *hpx::get_error_thread_id()*, *hpx::get_error_backtrace()*, *hpx::get_error_env()*, *hpx::get_error()*, *hpx::get_error_what()*, *hpx::get_error_thread_description()*

Parameters

`xi` – The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: *hpx::exception_info*, *hpx::error_code*, *std::exception*, or *std::exception_ptr*.

Throws

`std::bad_alloc` – (if one of the required allocations fails)

Returns

The point runtime state at the point at which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

serialization

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/serialization/serialization_chunk.hpp

Defined in header hpx/serialization/serialization_chunk.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`serialization`**

Enums

enum class **`chunk_type`** : *std*::uint8_t

Values:

enumerator **`chunk_type_index`**

enumerator **`chunk_type_const_pointer`**

enumerator **`chunk_type_pointer`**

Functions

constexpr *serialization_chunk* **create_index_chunk**(*std*::size_t index, *std*::size_t size) noexcept

constexpr *serialization_chunk* **create_const_pointer_chunk**(void const *pos, *std*::size_t size) noexcept

Zero-copy chunk referring to immutable caller-owned memory (save path). Parcelports must treat this like `chunk_type_pointer` for transmission.

constexpr *serialization_chunk* **create_pointer_chunk**(void *pos, *std*::size_t size) noexcept

Zero-copy chunk referring to mutable memory (typically receive path).

constexpr *serialization_chunk* **create_pointer_chunk**(void const *pos, *std*::size_t size) noexcept

Backward-compatible overload for const storage; same as `create_const_pointer_chunk`.

constexpr *serialization_chunk* **create_pointer_chunk**(*std*::nullptr_t, *std*::size_t size) noexcept

Create a mutable-pointer chunk with a null address.

union **chunk_data**

Public Members

std::size_t **index_**

void const ***cpos_**

void ***pos_**

struct **serialization_chunk**

Public Functions

inline constexpr void const ***data**() const noexcept

Active union member depends on *type_*: use this for both pointer kinds (mutable storage is returned as `void` const*).

inline constexpr void ***data**() noexcept

Mutable view; only valid for `chunk_type_pointer` chunks.

inline constexpr *std*::size_t **size**() const noexcept

Public Members

chunk_data **data_**

std::size_t **size_**

chunk_type **type_**

synchronization

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::binary_semaphore

Defined in header hpx/semaphore.hpp[951].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **binary_semaphore**

A binary semaphore is a semaphore object that has only two states. binary_semaphore is an alias for specialization of hpx::counting_semaphore with *LeastMaxValue* being 1. HPX's implementation of binary_semaphore is more efficient than the default implementation of a counting semaphore with a unit resource count (hpx::counting_semaphore).

[952] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/stop_token.hpp

[953] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/stop_token.hpp

[954] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/stop_token.hpp

class **stop_source**

The stop_source class provides the means to issue a stop request, such as for hpx::jthread cancellation. A stop request made for one stop_source object is visible to all *stop_sources* and *hpx::stop_tokens* of the same associated stop-state; any hpx::stop_callback(s) registered for associated hpx::stop_token(s) will be invoked, and any *hpx::condition_variable_any* objects waiting on associated hpx::stop_token(s) will be awoken. Once a stop is requested, it cannot be withdrawn. Additional stop requests have no effect.

> **Note**
>
> For the purposes of hpx::jthread cancellation the stop_source object should be retrieved from the *hpx::jthread* object using *get_stop_source()*; or stop should be requested directly from the hpx::jthread object using *request_stop()*. This will then use the same associated stop-state as that passed into the hpx::jthread*'s* invoked function argument (i.e., the function being executed on its thread). For other uses, however, a stop_source can be constructed separately using the default constructor, which creates new stop-state.

hpx::stop_token

Defined in header hpx/stop_token.hpp[955].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::nostopstate*
- *hpx::stop_callback*
- *hpx::stop_source*
- *hpx::nostopstate_t*

class **stop_token**

The stop_token class provides the means to check if a stop request has been made or can be made, for its associated hpx::stop_source object. It is essentially a thread-safe "view" of the associated stop-state. The *stop_token* can also be passed to the constructor of hpx::stop_callback, such that the callback will be invoked if the stop_token*'s* associated hpx::stop_source is requested to stop. And stop_token can be passed to the interruptible waiting functions of hpx::condition_variable_any, to interrupt the condition variable's wait if stop is requested.

> **Note**
>
> A stop_token object is not generally constructed independently, but rather retrieved from a hpx::jthread or hpx::stop_source. This makes it share the same associated stop-state as the hpx::jthread or hpx::stop_source.

---

[955] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/stop_token.hpp

hpx::nostopstate_t

Defined in header hpx/stop_token.hpp[956].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::nostopstate*
- *hpx::stop_callback*
- *hpx::stop_source*
- *hpx::stop_token*

struct **`nostopstate_t`**

Unit type intended for use as a placeholder in *hpx::stop_source* non-default constructor, that makes the constructed *hpx::stop_source* empty with no associated stop-state.

hpx::recursive_mutex

Defined in header hpx/mutex.hpp[957].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

using `hpx::`**`recursive_mutex`** = detail::recursive_mutex_impl<>

hpx::once_flag

Defined in header hpx/mutex.hpp[958].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::call_once*

struct **`once_flag`**

The class `hpx::once_flag` is a helper structure for `hpx::call_once`. An object of type `hpx::once_flag` that is passed to multiple calls to `hpx::call_once` allows those calls to coordinate with each other such that only one of the calls will actually run to completion. `hpx::once_flag` is neither copyable nor movable.

hpx::call_once

Defined in header hpx/mutex.hpp[959].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::once_flag*

template<typename **F**, typename ...**Args**>
void `hpx::call_once`(*once_flag* &flag, *F* &&f, *Args*&&... args)

Executes the Callable object *f* exactly once, even if called concurrently, from several threads.

In detail:

- If, by the time *call_once* is called, flag indicates that *f* was already called, *call_once* returns right away (such a call to *call_once* is known as passive).
- Otherwise, *call_once* invokes `std::forward<Callable>(f)` with the arguments `std::forward<Args>(args)...` (as if by `hpx::invoke`). Unlike the `hpx::thread` constructor or `hpx::async`, the arguments are not moved or copied because they don't need to be transferred to another thread of execution. (such a call to *call_once* is known as active).
  - If that invocation throws an exception, it is propagated to the caller of *call_once*, and the flag is not flipped so that another call will be attempted (such a call to *call_once* is known as exceptional).
  - If that invocation returns normally (such a call to *call_once* is known as returning), the flag is flipped, and all other calls to *call_once* with the same flag are guaranteed to be passive. All active calls on the same flag form a single total order consisting of zero or more exceptional calls, followed by one returning call. The end of each active call synchronizes-with the next active call in that order. The return from the returning call synchronizes-with the returns from all passive calls on the same flag: this means that all concurrent calls to *call_once* are guaranteed to observe any side-effects made by the active call, with no additional synchronization.

Note

If concurrent calls to *call_once* pass different functions *f*, it is unspecified which f will be called. The selected function runs in the same thread as the *call_once* invocation it was passed to. Initialization of function-local statics is guaranteed to occur only once even when called from multiple threads, and may be more efficient than the equivalent code using `hpx::call_once`. The POSIX equivalent of this function is *pthread_once*.

Parameters

- **`flag`** – an object, for which exactly one function gets executed
- **`f`** – Callable object to invoke
- **`args`** – arguments to pass to the function

Throws

`std::system_error` – if any condition prevents calls to *call_once* from executing as specified or any exception thrown by *f*

---

[959] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/mutex.hpp

hpx::shared_mutex

Defined in header hpx/shared_mutex.hpp[960].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

using *hpx*::**shared_mutex** = detail::shared_mutex<>

The *shared_mutex* class is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. In contrast to other mutex types which facilitate exclusive access, a *shared_mutex* has two levels of access:

- *shared* - several threads can share ownership of the same mutex.
- *exclusive* - only one thread can own the mutex.

  If one thread has acquired the exclusive lock (through *lock*, *try_lock*), no other threads can acquire the lock (including the shared). If one thread has acquired the shared lock (through *lock_shared*, *try_lock_shared*), no other thread can acquire the exclusive lock, but can acquire the shared lock. Only when the exclusive lock has not been acquired by any thread, the shared lock can be acquired by multiple threads. Within one thread, only one lock (shared or exclusive) can be acquired at the same time. Shared mutexes are especially useful when shared data can be safely read by any number of threads simultaneously, but a thread may only write the same data when no other thread is reading or writing at the same time. The *shared_mutex* class satisfies all requirements of *SharedMutex* and *StandardLayoutType*.

hpx::latch

Defined in header hpx/latch.hpp[961].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **latch**

Latches are a thread coordination mechanism that allow one or more threads to block until an operation is completed. An individual latch is a single-use object; once the operation has been completed, the latch cannot be reused.

Subclassed by hpx::lcos::local::latch

hpx/synchronization/sliding_semaphore.hpp

Defined in header hpx/synchronization/sliding_semaphore.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

[960] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/shared_mutex.hpp

[961] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/latch.hpp

Typedefs

using **sliding_semaphore** = *sliding_semaphore_var*<>

template<typename **Mutex** = *hpx*::*spinlock*>

class **sliding_semaphore_var**

#include <sliding_semaphore.hpp> A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Sliding semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore. The difference to a counting semaphore is that a sliding semaphore will not limit the number of threads which are allowed to proceed, but will make sure that the difference between the (arbitrary) number passed to set and wait does not exceed a given threshold.

Public Functions

sliding_semaphore_var(*sliding_semaphore_var* const&) = delete

sliding_semaphore_var &**operator=**(*sliding_semaphore_var* const&) = delete

sliding_semaphore_var(*sliding_semaphore_var*&&) = delete

sliding_semaphore_var &**operator=**(*sliding_semaphore_var*&&) = delete

inline explicit **sliding_semaphore_var**(*std*::int64_t max_difference, *std*::int64_t lower_limit = 0) noexcept

Construct a new sliding semaphore.

Parameters

- **max_difference** – [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.
- **lower_limit** – [in] The initial lower limit.

inline void **set_max_difference**(*std*::int64_t max_difference, *std*::int64_t lower_limit = 0) noexcept

Set/Change the difference that will cause the semaphore to trigger

Parameters

- **max_difference** – [in] The max difference between the upper limit (as set by *wait()*) and the lower limit (as set by *signal()*) which is allowed without suspending any thread calling *wait()*.
- **lower_limit** – [in] The initial lower limit.

inline void **wait**(*std*::int64_t upper_limit)

Wait for the semaphore to be signaled.

Parameters

upper_limit – [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower_limit which was set by *signal()* is larger than the max_difference.

inline bool **`try_wait`**(*std*::int64_t upper_limit = 1)

Try to wait for the semaphore to be signaled.

Parameters

`upper_limit` – [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower_limit which was set by *signal()* is larger than the max_difference.

Returns

The function returns true if the calling thread would not block if it was calling *wait()*.

inline void **`signal`**(*std*::int64_t lower_limit)

Signal the semaphore.

Parameters

`lower_limit` – [in] The new lower limit. This will update the current lower limit of this semaphore. It will also re-schedule all suspended threads for which their associated upper limit is not larger than the lower limit plus the max_difference.

inline *std*::int64_t **`signal_all`**()

Private Types

using **`mutex_type`** = *Mutex*

using **`data_type`** = *lcos*::*local*::detail::sliding_semaphore_data<*mutex_type*>

Private Members

hpx::intrusive_ptr<*data_type*> **`data_`**

hpx::barrier

Defined in header hpx/barrier.hpp[962].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`OnCompletion`** = detail::empty_oncompletion>

class **`barrier`**

A barrier is a thread coordination mechanism whose lifetime consists of a sequence of barrier phases, where each phase allows at most an expected number of threads to block until the expected number of threads arrive at the barrier. [Note: A barrier is useful for managing repeated tasks that are handled by multiple threads. - end note] Each barrier phase consists of the following steps:

- The expected count is decremented by each call to arrive or arrive_and_drop.
- When the expected count reaches zero, the phase completion step is run. For the specialization with the default value of the CompletionFunction template parameter, the completion step is run as part of the call to arrive or arrive_and_drop that caused the expected count to reach zero. For other specializations, the completion step is run on one of the threads that arrived at the barrier during the phase.

---

[962] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/barrier.hpp

- When the completion step finishes, the expected count is reset to what was specified by the expected argument to the constructor, possibly adjusted by calls to arrive_and_drop, and the next phase starts.

Each phase defines a phase synchronization point. Threads that arrive at the barrier during the phase can block on the phase synchronization point by calling wait, and will remain blocked until the phase completion step is run. The phase completion step that is executed at the end of each phase has the following effects:

- Invokes the completion function, equivalent to completion().
- Unblocks all threads that are blocked on the phase synchronization point.

The end of the completion step strongly happens before the returns from all calls that were unblocked by the completion step. For specializations that do not have the default value of the CompletionFunction template parameter, the behavior is undefined if any of the barrier object's member functions other than wait are called while the completion step is in progress.

Concurrent invocations of the member functions of barrier, other than its destructor, do not introduce data races. The member functions arrive and arrive_and_drop execute atomically.

CompletionFunction shall meet the Cpp17MoveConstructible (Table 28) and Cpp17Destructible (Table 32) requirements. std::is_nothrow_invocable_v<CompletionFunction&> shall be true.

The default value of the CompletionFunction template parameter is an unspecified type, such that, in addition to satisfying the requirements of CompletionFunction, it meets the Cpp17DefaultConstructible requirements (Table 27) and completion() has no effects.

barrier::arrival_token is an unspecified type, such that it meets the Cpp17MoveConstructible (Table 28), Cpp17MoveAssignable (Table 30), and Cpp17Destructible (Table 32) requirements.

hpx::spinlock

Defined in header hpx/mutex.hpp[963].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

using `hpx::spinlock` = detail::spinlock<true>

`spinlock` is a type of lock that causes a thread attempting to obtain it to check for its availability while waiting in a loop continuously.

hpx::mutex

Defined in header hpx/mutex.hpp[964].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::timed_mutex*

class **`mutex`**

mutex class is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. *mutex* offers exclusive, non-recursive ownership semantics:

---

[963] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/mutex.hpp
[964] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/mutex.hpp

- A calling thread owns a mutex from the time that it successfully calls either *lock* or *try_lock* until it calls *unlock*.
- When a thread owns a *mutex*, all other threads will block (for calls to *lock*) or receive a *false* return value (for *try_lock*) if they attempt to claim ownership of the *mutex*.
- A calling thread must not own the *mutex* prior to calling *lock* or *try_lock*.

The behavior of a program is undefined if a *mutex* is destroyed while still owned by any threads, or a thread terminates while owning a *mutex*. The mutex class satisfies all requirements of Mutex[965] and StandardLayoutType[966].

hpx::mutex is neither copyable nor movable.

Subclassed by *hpx::timed_mutex*

hpx::timed_mutex

Defined in header hpx/mutex.hpp[967].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::mutex*

class **timed_mutex** : private *hpx*::*mutex*

The timed_mutex class is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. In a manner similar to *mutex*, timed_mutex offers exclusive, non-recursive ownership semantics. In addition, timed_mutex provides the ability to attempt to claim ownership of a timed_mutex with a timeout via the member functions *try_lock_for()* and *try_lock_until()*. The timed_mutex class satisfies all requirements of TimedMutex[968] and StandardLayoutType[969].

hpx::timed_mutex is neither copyable nor movable.

hpx::condition_variable

Defined in header hpx/condition_variable.hpp[970].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::condition_variable_any*
- *hpx::cv_status*

class **condition_variable**

The condition_variable class is a synchronization primitive that can be used to block a thread, or multiple threads at the same time, until another thread both modifies a shared variable (the condition), and notifies the condition_variable.

The thread that intends to modify the shared variable has to

[968] https://en.cppreference.com/w/cpp/named_req/TimedMutex

[969] https://en.cppreference.com/w/cpp/named_req/StandardLayoutType

[970] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/condition_variable.hpp

a. acquire a hpx::mutex (typically via *std::lock_guard*)
b. perform the modification while the lock is held
c. execute *notify_one* or *notify_all* on the *condition_variable* (the lock does not need to be held for notification)

Even if the shared variable is atomic, it must be modified under the mutex in order to correctly publish the modification to the waiting thread. Any thread that intends to wait on condition_variable has to

a. acquire a *std::unique_lock<hpx::mutex>*, on the same mutex as used to protect the shared variable
b. either
    i. check the condition, in case it was already updated and notified
    ii. execute *wait*, *await_for*, or *wait_until*. The wait operations atomically release the mutex and suspend the execution of the thread.
    iii. When the condition variable is notified, a timeout expires, or a spurious wakeup occurs, the thread is awakened, and the mutex is atomically reacquired. The thread should then check the condition and resume waiting if the wake-up was spurious. or

    i. use the predicated overload of *wait*, *wait_for*, and *wait_until*, which takes care of the three steps above.

hpx::condition_variable works only with *std::unique_lock<hpx::mutex>*. This restriction allows for maximal efficiency on some platforms. hpx::condition_variable_any provides a condition variable that works with any BasicLockable[971] object, such as *std::shared_lock*.

Condition variables permit concurrent invocation of the *wait*, *wait_for*, *wait_until*, *notify_one* and *notify_all* member functions.

The class hpx::condition_variable is a StandardLayoutType[972]. It is not CopyConstructible[973], MoveConstructible[974], CopyAssignable[975], or MoveAssignable[976].

hpx::condition_variable_any

Defined in header hpx/condition_variable.hpp[977].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::condition_variable*
- *hpx::cv_status*

class **`condition_variable_any`**

The condition_variable_any class is a generalization of hpx::condition_variable. Whereas hpx::condition_variable works only on *std::unique_lock<std::mutex>*, *a condition_variable_any* can operate on any lock that meets the BasicLockable[978] requirements.

See hpx::condition_variable for the description of the semantics of condition variables. It is not CopyConstructible[979], MoveConstructible[980], CopyAssignable[981], or MoveAssignable[982].

hpx::cv_status

Defined in header hpx/condition_variable.hpp[983].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::condition_variable*
- *hpx::condition_variable_any*

enum class *hpx*::**cv_status**

The scoped enumeration hpx::cv_status describes whether a timed wait returned because of timeout or not. hpx::cv_status is used by the *wait_for* and *wait_until* member functions of hpx::condition_variable and hpx::condition_variable_any.

Values:

enumerator **no_timeout**

The condition variable was awakened with *notify_all*, *notify_one*, or spuriously

enumerator **timeout**

the condition variable was awakened by timeout expiration

enumerator **error**

there was an error

hpx::counting_semaphore

Defined in header hpx/semaphore.hpp[984].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<*std*::ptrdiff_t **LeastMaxValue** = PTRDIFF_MAX>

class **counting_semaphore**

A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Counting semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore.

[982] https://en.cppreference.com/w/cpp/named_req/MoveAssignable

[983] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/condition_variable.hpp

[984] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/semaphore.hpp

Unlike hpx::mutex a counting_semaphore is not tied to threads of execution &#8212; acquiring a semaphore can occur on a different thread than releasing the semaphore, for example. All operations on counting_semaphore can be performed concurrently and without any relation to specific threads of execution, with the exception of the destructor which cannot be performed concurrently but can be performed on a different thread.

Semaphores are lightweight synchronization primitives used to constrain concurrent access to a shared resource. They are widely used to implement other synchronization primitives and, whenever both are applicable, can be more efficient than condition variables.

A counting semaphore is a semaphore object that models a non-negative resource count.

Class template counting_semaphore maintains an internal counter that is initialized when the semaphore is created. The counter is decremented when a thread acquires the semaphore, and is incremented when a thread releases the semaphore. If a thread tries to acquire the semaphore when the counter is zero, the thread will block until another thread increments the counter by releasing the semaphore.

Specializations of hpx::counting_semaphore are not DefaultConstructible[985], CopyConstructible[986], MoveConstructible[987], CopyAssignable[988], or MoveAssignable[989].

Note

counting_semaphore*'s try_acquire()* can spuriously fail.

Template Parameters

`LeastMaxValue` – counting_semaphore allows more than one concurrent access to the same resource, for at least *LeastMaxValue* concurrent accessors. As its name indicates, the *LeastMaxValue* is the minimum max value, not the actual max value. Thus *max()* can yield a number larger than *LeastMaxValue*.

hpx::no_mutex

Defined in header hpx/mutex.hpp[990].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **`no_mutex`**

`no_mutex` class can be used in cases where the shared data between multiple threads can be accessed simultaneously without causing inconsistencies.

hpx/synchronization/event.hpp

Defined in header hpx/synchronization/event.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **lcos**

namespace **local**

class **event**

#include <event.hpp> Event semaphores can be used for synchronizing multiple threads that need to wait for an event to occur. When the event occurs, all threads waiting for the event are woken up.

Public Functions

inline **event**() noexcept

Construct a new event semaphore.

inline bool **occurred**() const noexcept

Check if the event has occurred.

inline void **wait**()

Wait for the event to occur.

inline void **set**()

Release all threads waiting on this semaphore.

inline void **reset**() noexcept

Reset the event.

Private Types

using **mutex_type** = *hpx*::*spinlock*

Private Functions

inline void **wait_locked**(*std*::unique_lock<*mutex_type*> &l)

inline void **set_locked**(*std*::unique_lock<*mutex_type*> l)

Private Members

mutex_type **mtx_**

This mutex protects the queue.

local::detail::condition_variable **cond_**

std::atomic<bool> **event_**

tag_invoke

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::invoke

Defined in header hpx/functional.hpp[991].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **F**, typename ...**Ts**>
constexpr *util*::invoke_result_t<*F*, *Ts*&&...> `hpx::invoke`(*F* &&f, *Ts*&&... vs) noexcept(noexcept(HPX_INVOKE(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*vs*)...)))

Invokes the given callable object f with the content of the argument pack vs

Note

This function is similar to `std::invoke` (C++17)

Parameters

- **f** – Requires to be a callable object. If f is a member function pointer, the first argument in the pack will be treated as the callee (this object).
- **vs** – An arbitrary pack of arguments

Throws

`std::exception` – like objects thrown by call to object f with the argument types vs.

Returns

The result of the callable object when it's called with the given argument types.

---

[991] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

hpx/functional/tag_invoke.hpp

Defined in header hpx/functional/tag_invoke.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **functional**

Typedefs

template<typename **Tag**, typename ...**Args**>

using **tag_invoke_result** = invoke_result<decltype(*tag_invoke*), *Tag*, *Args*...>

`hpx::functional::tag_invoke_result<Tag, Args...>` is the trait returning the result type of the call hpx::functional::tag_invoke. This can be used in a SFINAE context.

template<typename **Tag**, typename ...**Args**>

using **tag_invoke_result_t** = typename *tag_invoke_result*<*Tag*, *Args*...>::type

`hpx::functional::tag_invoke_result_t<Tag, Args...>` evaluates to `hpx::functional::tag_invoke_result_t<Tag, Args...>::type`

Variables

constexpr *unspecified* **tag_invoke** = *unspecified*

The `hpx::functional::tag_invoke` name defines a constexpr object that is invocable with one or more arguments. The first argument is a 'tag' (typically a CPO). It is only invocable if an overload of tag_invoke() that accepts the same arguments could be found via ADL.

The evaluation of the expression `hpx::tag_invoke(tag, args...)` is equivalent to evaluating the unqualified call to `tag_invoke(decay-copy(tag), HPX_FORWARD(Args, args)...)`.

`hpx::functional::tag_invoke` is implemented against P1895.

Example: Defining a new customization point `foo`:

```
namespace mylib {
    inline constexpr
        struct foo_fn final : hpx::functional::tag<foo_fn>
        {
        } foo{};
}
```

Defining an object `bar` which customizes `foo`:

```
struct bar
{
    int x = 42;

    friend constexpr int tag_invoke(mylib::foo_fn, bar const& x)
```

(continues on next page)

(continued from previous page)

```
    {
        return b.x;
    }
};
```

Using the customization point:

```
static_assert(42 == mylib::foo(bar{}), "The answer is 42");
```

template<typename **Tag**, typename ...**Args**>

constexpr bool **is_tag_invocable_v** = is_tag_invocable<*Tag*, *Args*...>::value

`hpx::functional::is_tag_invocable_v<Tag, Args...>` evaluates to `hpx::functional::is_tag_invocable<Tag, Args...>::value`

template<typename **Tag**, typename ...**Args**>

constexpr bool **is_nothrow_tag_invocable_v** = is_nothrow_tag_invocable<*Tag*, *Args*...>::value

`hpx::functional::is_tag_invocable_v<Tag, Args...>` evaluates to `hpx::functional::is_tag_invocable<Tag, Args...>::value`

namespace **unspecified**

hpx::is_invocable

Defined in header hpx/type_traits.hpp[992].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_invocable_r*

template<typename **F**, typename ...**Ts**>

struct **is_invocable** : public *hpx*::detail::is_invocable_impl<*F*&&(*Ts*&&...)>

Determines whether *F* can be invoked with the arguments *Ts*…. Formally, determines whether

```
INVOKE(std::declval<F>(), std::declval<Ts>()...)
```

is well-formed when treated as an unevaluated operand, where *INVOKE* is the operation defined in *Callable*.

F, R and all types in the parameter pack Ts shall each be a complete type, (possibly cv-qualified) void, or an array of unknown bound. Otherwise, the behavior is undefined. If an instantiation of a template above depends, directly or indirectly, on an incomplete type, and that instantiation could yield a different result if that type were hypothetically completed, the behavior is undefined.

[992] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/type_traits.hpp

hpx::is_invocable_r

Defined in header hpx/type_traits.hpp[993].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::is_invocable*

template<typename **R**, typename **F**, typename ...**Ts**>

struct **`is_invocable_r`** : public *hpx*::detail::is_invocable_r_impl<*F*&&(*Ts*&&...), *R*>

Determines whether *F* can be invoked with the arguments *Ts*… to yield a result that is convertible to *R* and the implicit conversion does not bind a reference to a temporary object (since C++23). If *R* is *cv* void, the result can be any type. Formally, determines whether

```
INVOKE<R>(std::declval<F>(), std::declval<Ts>()...)
```

is well-formed when treated as an unevaluated operand, where *INVOKE* is the operation defined in *Callable*. Determines whether *F* can be invoked with the arguments *Ts*…. Formally, determines whether

```
INVOKE(std::declval<F>(), std::declval<Ts>()...)
```

is well-formed when treated as an unevaluated operand, where *INVOKE* is the operation defined in *Callable*.

F, R and all types in the parameter pack Ts shall each be a complete type, (possibly cv-qualified) void, or an array of unknown bound. Otherwise, the behavior is undefined. If an instantiation of a template above depends, directly or indirectly, on an incomplete type, and that instantiation could yield a different result if that type were hypothetically completed, the behavior is undefined.

testing

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/testing/performance.hpp

Defined in header hpx/testing/performance.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`util`**

---

[993] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/type_traits.hpp

Functions

void **perftests_cfg**(*hpx*::program_options::options_description &cmdline)

void **perftests_init**(*hpx*::program_options::variables_map const &vm, *std*::string const test_name)

void **perftests_report**(*std*::string const &name, *std*::string const &exec, *std*::size_t const steps, *hpx*::*function*<void()> &&test, *hpx*::*function*<void()> pretest = nullptr)

void **perftests_print_times**()

void **perftests_report**(*std*::string const &name, *std*::string const &exec, *std*::size_t const steps, *std*::size_t const warmup, *hpx*::*function*<void()> &&test, *hpx*::*function*<void()> pretest = nullptr)

Like the perftests_report above, but runs *test* (after *pretest*) *warmup* times untimed before the *steps* timed runs, instead of the default (40 times with nanobench, once without). For tests whose runs take long, where the default warmup takes much longer than the timed runs.

Variables

bool **print_cdash_img**

std::string **test_name_**

thread_pool_util

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/thread_pool_util/thread_pool_suspension_helpers.hpp

Defined in header hpx/thread_pool_util/thread_pool_suspension_helpers.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

Functions

hpx::*future*<void> **`resume_processing_unit`**(*thread_pool_base* &pool, *std*::size_t virt_core)

Resumes the given processing unit. When the processing unit has been resumed the returned future will be ready.

> **Note**
>
> Can only be called from an HPX thread. Use resume_processing_unit_cb or to resume the processing unit from outside HPX. Requires that the pool has threads::policies::enable_elasticity set.

Parameters

- **`pool`** – [in] The thread pool to resume a processing unit on.
- **`virt_core`** – [in] The processing unit on the pool to be resumed. The processing units are indexed starting from 0.

Returns

A `future<void>` which is ready when the given processing unit has been resumed.

void **`resume_processing_unit_cb`**(*thread_pool_base* &pool, *hpx*::*function*<void()> callback, *std*::size_t virt_core, *error_code* &ec = *throws*)

Resumes the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been resumed.

> **Note**
>
> Requires that the pool has threads::policies::enable_elasticity set.

Parameters

- **`pool`** – [in] The thread pool to resume a processing unit on.
- **`callback`** – [in] Callback which is called when the processing unit has been suspended.
- **`virt_core`** – [in] The processing unit to resume.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<void> **`suspend_processing_unit`**(*thread_pool_base* &pool, *std*::size_t virt_core)

Suspends the given processing unit. When the processing unit has been suspended the returned future will be ready.

> **Note**
>
> Can only be called from an HPX thread. Use suspend_processing_unit_cb or to suspend the processing unit from outside HPX. Requires that the pool has threads::policies::enable_elasticity set.

Parameters

- **`pool`** – [in] The thread pool to suspend a processing unit from.
- **`virt_core`** – [in] The processing unit on the pool to be suspended. The processing units are indexed starting from 0.

Throws

`hpx::exception` – if called from outside the HPX runtime.

Returns

A `future<void>` which is ready when the given processing unit has been suspended.

void **`suspend_processing_unit_cb`**(*hpx*::*function*<void()> callback, *thread_pool_base* &pool, *std*::size_t virt_core, *error_code* &ec = *throws*)

Suspends the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been suspended.

Note

Requires that the pool has threads::policies::enable_elasticity set.

Parameters

- **`pool`** – [in] The thread pool to suspend a processing unit from.
- **`callback`** – [in] Callback which is called when the processing unit has been suspended.
- **`virt_core`** – [in] The processing unit to suspend.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<void> **`resume_pool`**(*thread_pool_base* &pool)

Resumes the thread pool. When the all OS threads on the thread pool have been resumed the returned future will be ready.

Note

Can only be called from an HPX thread. Use resume_cb or resume_direct to suspend the pool from outside HPX.

Parameters

`pool` – [in] The thread pool to resume.

Throws

`hpx::exception` – if called from outside the HPX runtime.

Returns

A `future<void>` which is ready when the thread pool has been resumed.

void **`resume_pool_cb`**(*thread_pool_base* &pool, *hpx*::*function*<void()> callback, *error_code* &ec = *throws*)

Resumes the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been resumed.

Parameters

- **`pool`** – [in] The thread pool to resume.
- **`callback`** – [in] called when the thread pool has been resumed.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<void> **`suspend_pool`**(*thread_pool_base* &pool)

Suspends the thread pool. When the all OS threads on the thread pool have been suspended the returned future will be ready.

Note

Can only be called from an HPX thread. Use suspend_cb or suspend_direct to suspend the pool from outside HPX. A thread pool cannot be suspended from an HPX thread running on the pool itself.

Parameters

`pool` – [in] The thread pool to suspend.

Throws

`hpx::exception` – if called from outside the HPX runtime.

Returns

A `future<void>` which is ready when the thread pool has been suspended.

void **`suspend_pool_cb`**(*thread_pool_base* &pool, *hpx*::*function*<void()> callback, *error_code* &ec = *throws*)

Suspends the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been suspended.

> **Note**
>
> A thread pool cannot be suspended from an HPX thread running on the pool itself.

Parameters

- **`pool`** – [in] The thread pool to suspend.
- **`callback`** – [in] called when the thread pool has been suspended.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if called from an HPX thread which is running on the pool itself.

thread_support

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::unlock_guard

Defined in header hpx/mutex.hpp[994].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`Lock`**>

class **`unlock_guard`**

The class *`unlock_guard`* is a mutex wrapper that provides a convenient mechanism for releasing a mutex for the duration of a scoped block.

`unlock_guard` performs the opposite functionality of `lock_guard`.

When a `lock_guard` object is created, it attempts to take ownership of the mutex it is given. When control leaves the scope in which the `lock_guard` object was created, the `lock_guard` is destructed and the mutex is released. Accordingly, when an *`unlock_guard`* object is created, it attempts to release the ownership of the mutex it is given. So, when control leaves the scope in which the *`unlock_guard`* object was created, the *`unlock_guard`* is destructed and the mutex is owned again. In this way, the mutex is unlocked in the constructor and locked in the destructor, so that one can have an unlocked section within a locked one.

> **Note**
>
> *`unlock_guard`* is non-copyable and non-movable.

---

[994] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/mutex.hpp

Template Parameters

Lock – The type of the lockable object managed by the *unlock_guard*.

hpx/thread_support/spinlock.hpp

Defined in header hpx/thread_support/spinlock.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **util**

threading

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::thread

Defined in header hpx/thread.hpp[995].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::this_thread::yield*
- *hpx::this_thread::get_id*
- *hpx::this_thread::sleep_for*
- *hpx::this_thread::sleep_until*

class **thread**

The class thread represents a single thread of execution. Threads allow multiple functions to execute concurrently. Threads begin execution immediately upon construction of the associated thread object (pending any OS scheduling delays), starting at the top-level function provided as a constructor argument. The return value of the top-level function is ignored and if it terminates by throwing an exception, *hpx::terminate* is called. The top-level function may communicate its return value or an exception to the caller via hpx::promise or by modifying shared variables (which may require synchronization, see *hpx::mutex* and hpx::atomic) *hpx::thread* objects may also be in the state that does not represent any thread (after default construction, move from, detach, or join), and a thread of execution may not be associated with any thread objects (after detach). No two *hpx::thread* objects may represent the same thread of execution; hpx::thread is not *CopyConstructible* or *CopyAssignable*, although it is *MoveConstructible* and *MoveAssignable*.

---

[995] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/thread.hpp

hpx::this_thread::yield

Defined in header hpx/thread.hpp[996].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::thread*
- *hpx::this_thread::get_id*
- *hpx::this_thread::sleep_for*
- *hpx::this_thread::sleep_until*

void `hpx::this_thread::`**`yield`**`()` noexcept

Provides a hint to the implementation to reschedule the execution of threads, allowing other threads to run.

> **Note**
>
> The exact behavior of this function depends on the implementation, in particular on the mechanics of the OS scheduler in use and the state of the system. For example, a first-in-first-out realtime scheduler (SCHED_FIFO in Linux) would suspend the current thread and put it on the back of the queue of the same-priority threads that are ready to run (and if there are no other threads at the same priority, yield has no effect).

hpx::this_thread::get_id

Defined in header hpx/thread.hpp[997].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::thread*
- *hpx::this_thread::yield*
- *hpx::this_thread::sleep_for*
- *hpx::this_thread::sleep_until*

thread::id `hpx::this_thread::`**`get_id`**`()` noexcept

Returns the id of the current thread.

---

[996] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/thread.hpp

[997] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/thread.hpp

hpx::this_thread::sleep_for

Defined in header hpx/thread.hpp[998].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::thread*
- *hpx::this_thread::yield*
- *hpx::this_thread::get_id*
- *hpx::this_thread::sleep_until*

inline void `hpx::this_thread::sleep_for(hpx::chrono::steady_duration const &rel_time)`

Blocks the execution of the current thread for at least the specified *rel_time*. This function may block for longer than *rel_time* due to scheduling or resource contention delays.

It is recommended to use a steady clock to measure the duration. If an implementation uses a system clock instead, the wait time may also be sensitive to clock adjustments.

Parameters

`rel_time` – time duration to sleep

hpx::this_thread::sleep_until

Defined in header hpx/thread.hpp[999].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::thread*
- *hpx::this_thread::yield*
- *hpx::this_thread::get_id*
- *hpx::this_thread::sleep_for*

void `hpx::this_thread::sleep_until(hpx::chrono::steady_time_point const &abs_time)`

Blocks the execution of the current thread until specified *abs_time* has been reached.

It is recommended to use the clock tied to *abs_time*, in which case adjustments of the clock may be taken into account. Thus, the duration of the block might be more or less than `abs_time - Clock::now()` at the time of the call, depending on the direction of the adjustment and whether it is honored by the implementation. The function also may block until after *abs_time* has been reached due to process scheduling or resource contention delays.

Parameters

`abs_time` – absolute time to block until

---

[998] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/thread.hpp

[999] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/thread.hpp

hpx::jthread

Defined in header hpx/jthread.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **jthread**

The class *jthread* represents a single thread of execution. It has the same general behavior as hpx::thread, except that *jthread* automatically rejoins on destruction, and can be cancelled/stopped in certain situations. Threads begin execution immediately upon construction of the associated thread object (pending any OS scheduling delays), starting at the top-level function provided as a constructor argument. The return value of the top-level function is ignored and if it terminates by throwing an exception, *hpx::terminate* is called. The top-level function may communicate its return value or an exception to the caller via hpx::promise or by modifying shared variables (which may require synchronization, see hpx::mutex and *hpx::atomic*) Unlike hpx::thread, the jthread logically holds an internal private member of type hpx::stop_source, which maintains a shared stop-state. The *jthread* constructor accepts a function that takes a hpx::stop_token as its first argument, which will be passed in by the jthread from its internal stop_source. This allows the function to check if stop has been requested during its execution, and return if it has. hpx::jthread objects may also be in the state that does not represent any thread (after default construction, move from, detach, or join), and a thread of execution may be not associated with any *jthread* objects (after detach). No two hpx::jthread objects may represent the same thread of execution; hpx::jthread is not *CopyConstructible* or *CopyAssignable*, although it is *MoveConstructible* and *MoveAssignable*.

threading_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::scoped_annotation

Defined in header hpx/functional.hpp[1000].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **scoped_annotation**

scoped_annotation associates a `name` with a section of code (scope). It can be used to visualize code execution in profiling tools like *Intel VTune*, *Apex Profiler*, etc. That allows analyzing performance to figure out which part(s) of code is (are) responsible for performance degradation, etc.

hpx/threading_base/thread_data.hpp

Defined in header hpx/threading_base/thread_data.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

[1000] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

Functions

constexpr *thread_data* ***get_thread_id_data**(thread_id_ref_type const &tid) noexcept

constexpr *thread_data* ***get_thread_id_data**(thread_id_type const &tid) noexcept

constexpr *tracing*::*region_init_data* **get_region_init_data**(*thread_data* const*) noexcept

constexpr *tracing*::*fiber_region_init_data* **get_fiber_region_init_data**(*thread_data* const*) noexcept

class **thread_data** : public detail::thread_data_reference_counting

#include <thread_data.hpp> A *thread* is the representation of a HPX thread. It's a first class object in HPX. In our implementation this is a user level thread running on top of one of the OS threads spawned by the *thread-manager*.

A *thread* encapsulates:
- A thread status word (see the functions *thread::get_state* and *thread::set_state*)
- A function to execute (the thread function)
- A frame (in this implementation this is a block of memory used as the threads stack)
- A block of registers (not implemented yet)

Generally, *threads* are not created or executed directly. All functionality related to the management of *threads* is implemented by the thread-manager.

Public Types

using **mutex_type** = *util*::detail::spinlock_no_backoff

Public Functions

thread_data(*thread_data* const&) = delete

thread_data(*thread_data*&&) = delete

thread_data &**operator=**(*thread_data* const&) = delete

thread_data &**operator=**(*thread_data*&&) = delete

inline thread_state **get_state**(*std*::memory_order const order = *std*::memory_order_acquire) const noexcept

The get_state function queries the state of this thread instance.

Note

This function will seldom be used directly. Most of the time the state of a thread will be retrieved by using the function *threadmanager::get_state*.

Returns

This function returns the current state of this thread. It will return one of the values as defined by the *thread_state* enumeration.

inline thread_state **set_state**(*thread_schedule_state* const state, *thread_restart_state* state_ex = *thread_restart_state*::*unknown*, *std*::memory_order const load_order = *std*::memory_order_acquire, *std*::memory_order const exchange_order = *std*::memory_order_acq_rel) const noexcept

The set_state function changes the state of this thread instance.

Note

This function will seldom be used directly. Most of the time the state of a thread will have to be changed using the thread-manager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status *threadmanager::set_state* should be used.

Parameters

- **state** – [in] The new state to be set for the thread.
- **state_ex** – [in]
- **load_order** – [in]
- **exchange_order** – [in]

inline bool **set_state_tagged**(*thread_schedule_state* const newstate, thread_state const &prev_state, thread_state &new_tagged_state, *std*::memory_order const exchange_order = *std*::memory_order_acq_rel) const noexcept

inline bool **restore_state**(thread_state const new_state, thread_state const old_state, *std*::memory_order const load_order = *std*::memory_order_relaxed, *std*::memory_order const load_exchange = *std*::memory_order_acq_rel) const noexcept

The restore_state function changes the state of this thread instance depending on its current state. It will change the state atomically only if the current state is still the same as passed as the second parameter. Otherwise, it won't touch the thread state of this instance.

Note

This function will seldom be used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread's status word. To change the thread's scheduling status *threadmanager::set_state* should be used.

Parameters

- **new_state** – [in] The new state to be set for the thread.
- **old_state** – [in] The old state of the thread which still has to be the current state.
- **load_order** – [in]
- **load_exchange** – [in]

Returns

This function returns *true* if the state has been changed successfully

inline bool **restore_state**(*thread_schedule_state* const new_state, *thread_restart_state* const state_ex, thread_state old_state, *std*::memory_order const load_exchange = *std*::memory_order_acq_rel) const noexcept

char const ***get_fiber_name**() const noexcept inline constexpr *thread_priority* **`get_priority`**() const noexcept

inline void **`set_priority`**(*thread_priority* const priority) noexcept

inline bool **`is_background`**() const noexcept

inline void **`set_is_background`**() noexcept

inline constexpr bool **`should_emit_lifecycle`**() const noexcept

True if this task's lifecycle events should be emitted.

On Tracy, reflects the 1/N sample decision made once at ctor and *rebind_base*; the read is unlocked because no other code path ever writes *emit_lifecycle_* (unlike *state_* bits, which are mutated concurrently by *interrupt()*). On other backends, always true (their hooks are constexpr no-ops).

Returns

true if lifecycle events should be emitted for this task.

inline bool **`interruption_requested`**() const noexcept

inline bool **`interruption_enabled`**() const noexcept

inline bool **`set_interruption_enabled`**(bool const enable) noexcept

inline void **`interrupt`**(bool const flag = true)

bool **`interruption_point`**(bool throw_on_interrupt = true)

bool **`add_thread_exit_callback`**(*function*<void()> const &f)

void **`run_thread_exit_callbacks`**()

void **`free_thread_exit_callbacks`**()

inline bool **`runs_as_child`**(*std*::memory_order const mo = *std*::memory_order_acquire) const noexcept

inline void **`stop_running_as_child`**() noexcept

inline bool **`is_stackless`**() const noexcept

void **`destroy_thread`**() override

inline constexpr *policies*::scheduler_base ***`get_scheduler_base`**() const noexcept

inline constexpr *std*::uint16_t **`get_last_worker_thread_num`**() const noexcept

inline void **`set_last_worker_thread_num`**(*std*::uint16_t const last_worker_thread_num) noexcept

inline constexpr *std*::ptrdiff_t **`get_stack_size`**() const noexcept

inline *thread_stacksize* **`get_stack_size_enum`**() const noexcept

template<typename **`ThreadQueue`**>
inline constexpr *ThreadQueue* &**`get_queue`**() noexcept

inline coroutine_type::result_type **operator()**(*hpx*::execution_base::this_thread::detail::agent_storage *agent_storage)

Execute the thread function.

Returns

This function returns the thread state the thread should be scheduled from this point on. The thread manager will use the returned value to set the thread's scheduling status.

inline coroutine_type::result_type **invoke_directly**()

Directly execute the thread function (inline)

Returns

This function returns the thread state the thread should be scheduled from this point on. The thread manager will use the returned value to set the thread's scheduling status.

inline virtual thread_id_type **get_thread_id**() const

inline virtual *std*::size_t **get_thread_phase**() const noexcept

virtual *std*::size_t **get_thread_data**() const = 0

virtual *std*::size_t **set_thread_data**(*std*::size_t data) = 0

virtual void **init**() = 0

virtual void **rebind**(thread_init_data &init_data) = 0

inline *hpx*::*tracing*::*task_timer_data* **get_timer_data**() const noexcept

static char const ***get_safe_description**(*threads*::*thread_description* const &description, char const *fallback = "<unknown>") noexcept

static inline constexpr *std*::uint32_t **get_parent_locality_id**() noexcept

Return the locality of the parent thread.

static inline constexpr thread_id_type **get_parent_thread_id**() noexcept

Return the thread id of the parent thread.

static inline constexpr *std*::size_t **get_parent_thread_phase**() noexcept

Return the phase of the parent thread.

static inline constexpr *util*::backtrace const ***get_backtrace**() noexcept

static inline constexpr *util*::backtrace const ***set_backtrace**(*util*::backtrace const*) noexcept

Protected Functions

inline *thread_restart_state* **set_state_ex**(*thread_restart_state* const new_state, *std*::memory_order const load_order = *std*::memory_order_acquire, *std*::memory_order const load_exchange = *std*::memory_order_acq_rel) const noexcept

The set_state function changes the extended state of this thread instance.

> **Note**
>
> This function will seldom be used directly. Most of the time the state of a thread will have to be changed using the threadmanager.

Parameters

- **new_state** – [in] The new extended state to be set for the thread.
- **load_order** – [in]
- **load_exchange** – [in]

class **thread_pool_base**

#include <thread_pool_base.hpp> The base class used to manage a pool of OS threads.

Public Functions

virtual void **suspend_processing_unit_direct**(*std*::size_t virt_core, *error_code* &ec = *throws*) = 0

Suspends the given processing unit. Blocks until the processing unit has been suspended.

Parameters

- **virt_core** – [in] The processing unit on the pool to be suspended. The processing units are indexed starting from 0.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

virtual void **`resume_processing_unit_direct`**(*std*::size_t virt_core, *error_code* &ec = *throws*) = 0

Resumes the given processing unit. Blocks until the processing unit has been resumed.

Parameters

- **`virt_core`** – [in] The processing unit on the pool to be resumed. The processing units are indexed starting from 0.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

virtual void **`resume_direct`**(*error_code* &ec = *throws*) = 0

Resumes the thread pool. Blocks until all OS threads on the thread pool have been resumed.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

virtual void **`suspend_direct`**(*error_code* &ec = *throws*) = 0

Suspends the thread pool. Blocks until all OS threads on the thread pool have been suspended.

Note

A thread pool cannot be suspended from an HPX thread running on the pool itself.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if called from an HPX thread which is running on the pool itself.

hpx::annotated_function

Defined in header hpx/functional.hpp[1001].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **F**>
constexpr *F* &&`hpx::`**`annotated_function`**(*F* &&f, char const* = nullptr) noexcept

Returns a function annotated with the given annotation.

Annotating includes setting the thread description per thread id.

Parameters

`f` – Function to annotate

template<typename **F**>
constexpr *F* &&`hpx::`**`annotated_function`**(*F* &&f, *std*::string const&) noexcept

---

[1001] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

hpx/threading_base/register_thread.hpp

Defined in header hpx/threading_base/register_thread.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

Functions

template<typename **F**>
thread_function_type **make_thread_function**(*F* &&f)

template<typename **F**, typename ...**Ts**>
thread_function_type **make_thread_function_nullary**(*F* &&f, *Ts*&&... ts)

void **register_thread**(*threads*::thread_init_data &data, *threads*::*thread_pool_base* *pool, *threads*::thread_id_ref_type &id, *error_code* &ec = *hpx*::*throws*)

Create a new *thread* using the given data.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters
- **data** – [in] The data to use for creating the thread.
- **pool** – [in] The thread pool to use for launching the work.
- **id** – [out] The id of the newly created thread (if applicable)
- **ec** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`invalid_status` – if the runtime system has not been started yet.

Returns

This function will return the internal id of the newly created HPX-thread.

threads::thread_id_ref_type **register_thread**(*threads*::thread_init_data &data, *threads*::*thread_pool_base* *pool, *error_code* &ec = *hpx*::*throws*)

void **register_thread**(*threads*::thread_init_data &data, *threads*::thread_id_ref_type &id, *error_code* &ec = *throws*)

Create a new *thread* using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`data`** – [in] The data to use for creating the thread.
- **`id`** – [out] The id of the newly created thread (if applicable)
- **`ec`** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`invalid_status` – if the runtime system has not been started yet.

Returns

This function will return the internal id of the newly created HPX-thread.

threads::thread_id_ref_type **`register_thread`**(*threads*::thread_init_data &data, *error_code* &ec = *throws*)

thread_id_ref_type **`register_work`**(*threads*::thread_init_data &data, *threads*::*thread_pool_base* *pool, *error_code* &ec = *hpx*::*throws*)

Create a new work item using the given data.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`data`** – [in] The data to use for creating the thread.
- **`pool`** – [in] The thread pool to use for launching the work.
- **`ec`** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`invalid_status` – if the runtime system has not been started yet.

thread_id_ref_type **`register_work`**(*threads*::thread_init_data &data, *error_code* &ec = *throws*)

Create a new work item using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`data`** – [in] The data to use for creating the thread.
- **`ec`** – [in,out] This represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`invalid_status` – if the runtime system has not been started yet.

hpx::threads::with_task_size

Defined in header hpx/functional.hpp[1002].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<*task_size* **Size**, typename **F**>
constexpr sized_function<*std*::decay_t<*F*>, *Size*> hpx::threads::**with_task_size**(*F* &&f)

Returns a function that carries the given task size.

Parameters

f – Function whose task is expected to run for about *Size*

hpx/threading_base/print.hpp

Defined in header hpx/threading_base/print.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/threading_base/thread_description.hpp

Defined in header hpx/threading_base/thread_description.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

Functions

std::ostream &**operator<<**(*std*::ostream&, *thread_description* const&)

std::string **as_string**(*thread_description* const &desc)

threads::*thread_description* **get_thread_description**(thread_id_type const &id, *error_code* &ec = *throws*)

The function get_thread_description is part of the thread related API allows to query the description of one of the threads known to the thread-manager.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **id** – [in] The thread id of the thread being queried.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

[1002] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/core/include_local/include/hpx/functional.hpp

Returns

This function returns the description of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the string "<unknown>".

threads::*thread_description* **set_thread_description**(thread_id_type const &id, *threads*::*thread_description* const &desc = *threads*::*thread_description*(), *error_code* &ec = *throws*)

threads::*thread_description* **get_thread_lco_description**(thread_id_type const &id, *error_code* &ec = *throws*)

threads::*thread_description* **set_thread_lco_description**(thread_id_type const &id, *threads*::*thread_description* const &desc = *threads*::*thread_description*(), *error_code* &ec = *throws*)

namespace **hpx**

namespace **this_thread**

Functions

threads::*thread_restart_state* **suspend**(*threads*::*thread_schedule_state* state, *threads*::thread_id_type nextid, *threads*::*thread_description* const &description = *threads*::*thread_description*("this_thread::suspend"), *hpx*::*error_code* &ec = *hpx*::*throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

> **Note**
>
> Must be called from within a HPX-thread.

Throws

`If – &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

inline *threads*::*thread_restart_state* **suspend**(*threads*::*thread_schedule_state* state = *threads*::*thread_schedule_state*::*pending*, *threads*::*thread_description* const &description = *threads*::*thread_description*("this_thread::suspend"), *hpx*::*error_code* &ec = *hpx*::*throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

Note

Must be called from within a HPX-thread.

Throws

`If` – `&ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

threads::*thread_restart_state* **suspend**(*hpx*::chrono::*steady_time_point* const &abs_time, *threads*::thread_id_type id, *threads*::*thread_description* const &description = *threads*::*thread_description*("this_thread::suspend"), *hpx*::*error_code* &ec = *hpx*::*throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

Note

Must be called from within a HPX-thread.

Throws

`If` – `&ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

inline *threads*::*thread_restart_state* **suspend**(*hpx*::chrono::*steady_time_point* const &abs_time, *threads*::*thread_description* const &description = *threads*::*thread_description*("this_thread::suspend"), *hpx*::*error_code* &ec = *hpx*::*throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads at the given time.

Note

Must be called from within a HPX-thread.

Throws

`If – &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

inline *threads*::*thread_restart_state* **suspend**(*hpx*::chrono::*steady_duration* const &rel_time, *threads*::*thread_description* const &description = *threads*::*thread_description*("this_thread::suspend"), *hpx*::*error_code* &ec = *hpx*::*throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

Note

Must be called from within a HPX-thread.

Throws

`If – &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

inline *threads*::*thread_restart_state* **suspend**(*hpx*::chrono::*steady_duration* const &rel_time, *threads*::thread_id_type const &id, *threads*::*thread_description* const &description = *threads*::*thread_description*("this_thread::suspend"), *hpx*::*error_code* &ec = *hpx*::*throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given duration.

Note

Must be called from within a HPX-thread.

Throws

`If – &ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

inline *threads*::*thread_restart_state* **suspend**(*std*::uint64_t ms, *threads*::*thread_description* const &description = *threads*::*thread_description*("this_thread::suspend"), *hpx*::*error_code* &ec = *hpx*::*throws*)

The function *suspend* will return control to the thread manager (suspends the current thread). It sets the new state of this thread to *suspended* and schedules a wakeup for this threads after the given time (specified in milliseconds).

Note

Must be called from within a HPX-thread.

Throws

`If` – `&ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

threads::*thread_pool_base* ***`get_pool`**(*hpx*::*error_code* &ec = *hpx*::*throws*)

Returns a pointer to the pool that was used to run the current thread

Throws

`If` – `&ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

namespace **`threads`**

Functions

thread_state **`set_thread_state`**(thread_id_type const &id, *thread_schedule_state* state = *thread_schedule_state*::*pending*, *thread_restart_state* stateex = *thread_restart_state*::*signaled*, *thread_priority* priority = *thread_priority*::*normal*, bool retry_on_active = true, *hpx*::*error_code* &ec = *hpx*::*throws*)

Set the thread state of the *thread* referenced by the thread_id *id*.

Note

If the thread referenced by the parameter *id* is in *thread_state::active* state this function schedules a new thread which will set the state of the thread as soon as it is not active anymore. The function returns *thread_state::active* in this case.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread the state should be modified for.
- **`state`** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **`stateex`** – [in] The new extended state to be set for the thread referenced by the *id* parameter.
- **`priority`** – [in]

- **`retry_on_active`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns the previous state of the thread referenced by the *id* parameter. It will return one of the values as defined by the *thread_state* enumeration. If the thread is not known to the thread-manager the return value will be *thread_state::unknown*.

thread_id_ref_type **`set_thread_state`**(thread_id_type const &id, *hpx*::chrono::*steady_time_point* const &abs_time, *std*::atomic<bool> *started, *thread_schedule_state* state = *thread_schedule_state*::*pending*, *thread_restart_state* stateex = *thread_restart_state*::*timeout*, *thread_priority* priority = *thread_priority*::*normal*, bool retry_on_active = true, *hpx*::*error_code* &ec = *hpx*::*throws*)

Set the thread state of the *thread* referenced by the thread_id *id*.

Set a timer to set the state of the given *thread* to the given new value after it expired (at the given time)

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread the state should be modified for.
- **`abs_time`** – [in] Absolute point in time for the new thread to be run
- **`started`** – [in,out] A helper variable allowing to track the state of the timer helper thread
- **`state`** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **`stateex`** – [in] The new extended state to be set for the thread referenced by the *id* parameter.
- **`priority`** – [in]
- **`retry_on_active`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

inline thread_id_ref_type **`set_thread_state`**(thread_id_type const &id, *hpx*::chrono::*steady_time_point* const &abs_time, *thread_schedule_state* state = *thread_schedule_state*::*pending*, *thread_restart_state* stateex = *thread_restart_state*::*timeout*, *thread_priority* priority = *thread_priority*::*normal*, bool retry_on_active = true, *hpx*::*error_code*& = *throws*)

inline thread_id_ref_type **`set_thread_state`**(thread_id_type const &id, *hpx*::chrono::*steady_duration* const &rel_time, *thread_schedule_state* state = *thread_schedule_state*::*pending*, *thread_restart_state* stateex = *thread_restart_state*::*timeout*, *thread_priority* priority = *thread_priority*::*normal*, bool retry_on_active = true, *hpx*::*error_code* &ec = *hpx*::*throws*)

Set the thread state of the *thread* referenced by the thread_id *id*.

Set a timer to set the state of the given *thread* to the given new value after it expired (after the given duration)

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters
- **`id`** – [in] The thread id of the thread the state should be modified for.
- **`rel_time`** – [in] Time duration after which the new thread should be run
- **`state`** – [in] The new state to be set for the thread referenced by the *id* parameter.
- **`stateex`** – [in] The new extended state to be set for the thread referenced by the *id* parameter.
- **`priority`** – [in]
- **`retry_on_active`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

thread_state **`get_thread_state`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*) noexcept

The function get_thread_backtrace is part of the thread related API allows to query the currently stored thread back trace (which is captured during thread suspension).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception. The function get_thread_state is part of the thread related API. It queries the state of one of the threads known to the thread-manager.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters
- **`id`** – [in] The thread id of the thread being queried.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.
- **`id`** – [in] The thread id of the thread the state should be modified for.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns the currently captured stack back trace of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be the zero.

Returns

This function returns the thread state of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be *terminated*.

std::size_t **`get_thread_phase`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*) noexcept

The function get_thread_phase is part of the thread related API. It queries the phase of one of the threads known to the thread-manager.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread the phase should be modified for.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns the thread phase of the thread referenced by the *id* parameter. If the thread is not known to the thread-manager the return value will be ~0.

bool **`get_thread_interruption_enabled`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*)

Returns whether the given thread can be interrupted at this point.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread which should be queried.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if the given thread can be interrupted at this point in time. It will return *false* otherwise.

bool **`set_thread_interruption_enabled`**(thread_id_type const &id, bool enable, *hpx*::*error_code* &ec = *hpx*::*throws*)

Set whether the given thread can be interrupted at this point.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread which should receive the new value.
- **`enable`** – [in] This value will determine the new interruption enabled status for the given thread.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns the previous value of whether the given thread could have been interrupted.

bool **`get_thread_interruption_requested`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*)

Returns whether the given thread has been flagged for interruption.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread which should be queried.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if the given thread was flagged for interruption. It will return *false* otherwise.

void **`interrupt_thread`**(thread_id_type const &id, bool flag, *hpx*::*error_code* &ec = *hpx*::*throws*)

Flag the given thread for interruption.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread which should be interrupted.
- **`flag`** – [in] The flag encodes whether the thread should be interrupted (if it is *true*), or 'uninterrupted' (if it is *false*).
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline void **`interrupt_thread`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*)

void **`interruption_point`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*)

Interrupt the current thread at this point if it was canceled. This will throw a thread_interrupted exception, which will cancel the thread.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread which should be interrupted.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

threads::*thread_priority* **`get_thread_priority`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*) noexcept

Return priority of the given thread

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread whose priority is queried.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::ptrdiff_t **`get_stack_size`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*) noexcept

Return stack size of the given thread

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The thread id of the thread whose priority is queried.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

threads::*thread_pool_base* ***`get_pool`**(thread_id_type const &id, *hpx*::*error_code* &ec = *hpx*::*throws*)

Returns a pointer to the pool that was used to run the current thread

Throws

`If` – `&ec != &throws`, never throws, but will set *ec* to an appropriate value when an error occurs. Otherwise, this function will throw an *hpx::exception* with an error code of *hpx::error::yield_aborted* if it is signaled with *wait_aborted*. If called outside a HPX-thread, this function will throw an *hpx::exception* with an error code of *hpx::error::null_thread_id*. If this function is called while the thread-manager is not running, it will throw an *hpx::exception* with an error code of *hpx::error::invalid_status*.

hpx/threading_base/tracing_sample_rate.hpp

Defined in header hpx/threading_base/tracing_sample_rate.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::get_worker_thread_num

Defined in header hpx/runtime.hpp[1003].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::get_local_worker_thread_num*
- *hpx::get_thread_pool_num*

std::size_t *`hpx`*::**`get_worker_thread_num`**() noexcept

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

[1003] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

Note

The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by *get_os_thread_count()*).

Note

This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

std::size_t *hpx*::**get_worker_thread_num**(*error_code* &ec) noexcept

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

Note

The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by *get_os_thread_count()*). It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note

This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

ec – [in,out] this represents the error status on exit (obsolete, ignored).

hpx::get_local_worker_thread_num

Defined in header hpx/runtime.hpp[1004].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::get_worker_thread_num*
- *hpx::get_thread_pool_num*

std::size_t *hpx*::**get_local_worker_thread_num**() noexcept

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

[1004] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

Note

The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note

This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

std::size_t *hpx*::**get_local_worker_thread_num**(*error_code* &ec) noexcept

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

Note

The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note

This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

`ec` – [in,out] this represents the error status on exit (obsolete, ignored).

hpx::get_thread_pool_num

Defined in header hpx/runtime.hpp[1005].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::get_worker_thread_num*
- *hpx::get_local_worker_thread_num*

std::size_t *hpx*::**get_thread_pool_num**() noexcept

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

[1005] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

Note

The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note

This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

std::size_t *hpx*::**get_thread_pool_num**(*error_code* &ec) noexcept

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

Note

The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note

This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

ec – [in,out] this represents the error status on exit (obsolete, ignored).

hpx/threading_base/threading_base_fwd.hpp

Defined in header hpx/threading_base/threading_base_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

Functions

thread_data ***get_self_id_data**() noexcept

The function *get_self_id_data* returns the data of the HPX thread id associated with the current thread (or nullptr if the current thread is not a HPX thread).

thread_self &**get_self**()

The function *get_self* returns a reference to the (OS thread specific) self reference to the current HPX thread.

thread_self ***get_self_ptr**() noexcept

The function *get_self_ptr* returns a pointer to the (OS thread specific) self reference to the current HPX thread.

thread_self_impl_type ***get_ctx_ptr**()

The function *get_ctx_ptr* returns a pointer to the internal data associated with each coroutine.

thread_self ***get_self_ptr_checked**(*error_code* &ec = *throws*)

The function *get_self_ptr_checked* returns a pointer to the (OS thread specific) self reference to the current HPX thread.

thread_id_type **get_self_id**() noexcept

The function *get_self_id* returns the HPX thread id of the current thread (or zero if the current thread is not a HPX thread).

inline thread_id_type **get_outer_self_id**() noexcept

The function *get_outer_self_id* returns the HPX thread id of the current outer thread (or zero if the current thread is not a HPX thread). This now always returns the same as *get_self_id*, even for directly executed threads.

thread_id_type **get_parent_id**() noexcept

The function *get_parent_id* returns the HPX thread id of the current thread's parent (or zero if the current thread is not a HPX thread).

> **Note**
>
> This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::size_t **get_parent_phase**() noexcept

The function *get_parent_phase* returns the HPX phase of the current thread's parent (or zero if the current thread is not a HPX thread).

> **Note**
>
> This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::ptrdiff_t **get_self_stacksize**() noexcept

The function *get_self_stacksize* returns the stack size of the current thread (or zero if the current thread is not a HPX thread).

thread_stacksize `get_self_stacksize_enum()` noexcept

The function *get_self_stacksize_enum* returns the stack size of the /.

std::uint32_t `get_parent_locality_id()` noexcept

The function *get_parent_locality_id* returns the id of the locality of the current thread's parent (or zero if the current thread is not a HPX thread).

Note

This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::uint64_t `get_self_component_id()` noexcept

The function *get_self_component_id* returns the lva of the component the current thread is acting on

Note

This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_TARGET_ADDRESS being defined.

namespace **policies**

namespace **tracing**

threadmanager

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/threadmanager/threadmanager.hpp

Defined in header hpx/threadmanager/threadmanager.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **threads**

class **threadmanager**

#include <threadmanager.hpp> The *thread-manager* class is the central instance of management for all (non-depleted) threads

Public Types

using **`notification_policy_type`** = *threads*::*policies*::callback_notifier

using **`pool_type`** = *std*::unique_ptr<*thread_pool_base*>

using **`pool_vector`** = *std*::vector<*pool_type*>

Public Functions

`threadmanager`(*hpx*::*util*::*runtime_configuration* &rtcfg_, *notification_policy_type* &notifier, detail::network_background_callback_type network_background_callback = detail::network_background_callback_type())

`threadmanager`(*threadmanager* const&) = delete

`threadmanager`(*threadmanager*&&) = delete

threadmanager &**`operator=`**(*threadmanager* const&) = delete

threadmanager &**`operator=`**(*threadmanager*&&) = delete

`~threadmanager`()

void **`init`**() const

void **`create_pools`**()

void **`print_pools`**(*std*::ostream&) const

FIXME move to private and add &#8212;hpx:printpools cmd line option.

thread_pool_base &**`default_pool`**() const

thread_pool_base &**`get_pool`**(*std*::string const &pool_name) const

thread_pool_base &**`get_pool`**(pool_id_type const &pool_id) const

thread_pool_base &**`get_pool`**(*std*::size_t thread_index) const

bool **`pool_exists`**(*std*::string const &pool_name) const

bool **`pool_exists`**(*std*::size_t pool_index) const

thread_id_ref_type **`register_work`**(thread_init_data &data, *error_code* &ec = *throws*) const

The function *register_work* adds a new work item to the thread manager. It doesn't immediately create a new *thread*, it just adds the task parameters (function, initial state and description) to the internal management data structures. The thread itself will be created when the number of existing threads drops below the number of threads specified by the constructors max_count parameter.

Parameters

- **`data`** – [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.
- **`ec`** –

void **register_thread**(thread_init_data &data, thread_id_ref_type &id, *error_code* &ec = *throws*) const

The function *register_thread* adds a new work item to the thread manager. It creates a new *thread*, adds it to the internal management data structures, and schedules the new thread, if appropriate.

Parameters

- **data** – [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.
- **id** – [out] This parameter will hold the id of the created thread. This id is guaranteed to be validly initialized before the thread function is executed.
- **ec** –

bool **run**() const

Run the thread manager's work queue. This function instantiates the specified number of OS threads in each pool. All OS threads are started to execute the function *tfunc*.

Returns

The function returns *true* if the thread manager has been started successfully, otherwise it returns *false*.

void **stop**(bool blocking = true) const

Forcefully stop the thread-manager.

Parameters

blocking –

bool **is_busy**() const

bool **is_idle**() const

void **wait**() const

bool **wait_for**(*hpx*::chrono::*steady_duration* const &rel_time) const

template<typename **StopToken**>
inline bool **wait_for**(*StopToken* &&stop_token, *hpx*::chrono::*steady_duration* const &rel_time) const

void **suspend**() const

void **resume**() const

hpx::state **status**() const

Return whether the thread manager is still running This returns the "minimal state", i.e. the state of the least advanced thread pool

std::int64_t **get_thread_count**(*thread_schedule_state* state = *thread_schedule_state*::*unknown*, *thread_priority* priority = *thread_priority*::*default_*, *std*::size_t num_thread = static_cast<*std*::size_t>(-1), bool reset = false) const

return the number of HPX-threads with the given state

Note

This function locks the internal OS lock in the thread manager

std::int64_t **get_idle_core_count**() const mask_type **`get_idle_core_mask`**() const

std::int64_t **`get_background_thread_count`**() const

bool **`enumerate_threads`**(*hpx*::*function*<bool(thread_id_type)> const &f, *thread_schedule_state* state = *thread_schedule_state*::*unknown*) const

void **`abort_all_suspended_threads`**() const

bool **`cleanup_terminated`**(bool delete_all) const

std::size_t **`get_os_thread_count`**() const

Return the number of OS threads running in this thread-manager.

This function will return correct results only if the thread-manager is running.

std::thread &**`get_os_thread_handle`**(*std*::size_t num_thread) const

void **`report_error`**(*std*::size_t num_thread, *std*::exception_ptr const &e) const

API functions forwarding to notification policy.

This notifies the thread manager that the passed exception has been raised. The exception will be routed through the notifier and the scheduler (which will result in it being passed to the runtime object, which in turn will report it to the console, etc.).

mask_type **`get_used_processing_units`**() const

Returns the mask identifying all processing units used by this thread manager.

hwloc_bitmap_ptr **`get_pool_numa_bitmap`**(*std*::string const &pool_name) const

void **`set_scheduler_mode`**(*threads*::*policies*::scheduler_mode mode, *hpx*::*threads*::mask_cref_type pu_mask) const noexcept

Defined in header hpx/thrust/algorithms.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **thrust**

Functions

template<typename **Tag**, typename **ThrustPolicy**, typename ...**Args**>
decltype(auto) **hpx_invoke**(*Tag* tag, *ThrustPolicy* &&policy, *Args*&&... args)

ADL hook dispatching HPX algorithm CPOs to Thrust backends.

When a Thrust execution policy is passed to an HPX algorithm CPO, this hook maps the call to the corresponding Thrust implementation. Async policies wrap the result in a future.

Template Parameters

- **Tag** – The algorithm CPO tag type.
- **ThrustPolicy** – A Thrust execution policy satisfying is_thrust_execution_policy.
- **Args** – Arguments forwarded to the Thrust algorithm.

Parameters

- **tag** – The algorithm CPO tag instance.
- **policy** – Thrust execution policy controlling dispatch.
- **args** – Arguments forwarded to the mapped algorithm.

Returns

The algorithm result, or a future thereof for async policies.

`~topology`()

inline *std*::size_t **`get_socket_number`**(*std*::size_t num_thread, [[maybe_unused]] *error_code* &ec = *throws*) const noexcept

Return the Socket number of the processing unit the given thread is running on.

Parameters

- **`num_thread`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline *std*::size_t **`get_numa_node_number`**(*std*::size_t num_thread, [[maybe_unused]] *error_code* &ec = *throws*) const noexcept

Return the NUMA node number of the processing unit the given thread is running on.

Parameters

- **`num_thread`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline *std*::size_t **`get_numa_distance`**(*std*::size_t node_a, *std*::size_t node_b) const noexcept

Return the hardware latency distance between two NUMA nodes. Values are sourced from hwloc's distance matrix when available; otherwise a standard default (10 = local, 20 = remote) is returned.

Parameters

- **`node_a`** – [in] logical index of the first NUMA node
- **`node_b`** – [in] logical index of the second NUMA node

mask_cref_type **`get_machine_affinity_mask`**(*error_code* &ec = *throws*) const noexcept

Return a bit mask where each set bit corresponds to a processing unit available to the application.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_type **`get_service_affinity_mask`**(mask_cref_type used_processing_units, *error_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the service threads in the application.

Parameters

- **`used_processing_units`** – [in] This is the mask of processing units which are not available for service threads.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **`get_socket_affinity_mask`**(*std*::size_t num_thread, *error_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the socket it is running on.

Parameters

- **`num_thread`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **`get_numa_node_affinity_mask`**(*std*::size_t num_thread, *error_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the NUMA domain it is running on.

Parameters

- **`num_thread`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **`get_core_affinity_mask`**(*std*::size_t num_thread, *error_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the core it is running on.

Parameters

- **`num_thread`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_cref_type **`get_thread_affinity_mask`**(*std*::size_t num_thread, *error_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread.

Parameters

- **`num_thread`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`set_thread_affinity_mask`**(mask_cref_type mask, *error_code* &ec = *throws*) const

Use the given bit mask to set the affinity of the given thread. Each set bit corresponds to a processing unit the thread will be allowed to run on.

Note

Use this function on systems where the affinity must be set from inside the thread itself.

Parameters

- **`mask`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

mask_type **`get_thread_affinity_mask_from_lva`**(void const *lva, *error_code* &ec = *throws*) const

Return a bit mask where each set bit corresponds to a processing unit co-located with the memory the given address is currently allocated on.

Parameters

- **`lva`** – [in]
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`print_affinity_mask`**(*std*::ostream &os, *std*::size_t num_thread, mask_cref_type m, *std*::string const &pool_name) const

Prints the given mask *m* to os in a human-readable form.

bool **`reduce_thread_priority`**(*error_code* &ec = *throws*) const

Reduce thread priority of the current thread.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

std::size_t **`get_number_of_sockets`**() const

Return the number of available NUMA domains.

std::size_t **`get_number_of_numa_nodes`**() const

Return the number of available NUMA domains.

std::size_t **`get_number_of_cores`**() const

Return the number of available cores.

std::size_t **`get_number_of_pus`**() const noexcept

Return the number of available hardware processing units.

std::size_t **`get_number_of_numa_node_cores`**(*std*::size_t numa) const

Return number of cores in given numa domain.

std::size_t **`get_number_of_numa_node_pus`**(*std*::size_t numa) const

Return number of processing units in a given numa domain.

std::size_t **`get_number_of_socket_pus`**(*std*::size_t socket) const

Return number of processing units in a given socket.

std::size_t **`get_number_of_core_pus`**(*std*::size_t core) const

Return number of processing units in given core.

std::size_t **`get_number_of_socket_cores`**(*std*::size_t socket) const

Return number of cores units in given socket.

inline *std*::size_t **`get_core_number`**(*std*::size_t num_thread, *error_code*& = *throws*) const

std::size_t **`get_pu_number`**(*std*::size_t num_core, *std*::size_t num_pu, *error_code* &ec = *throws*) const

std::size_t **`get_cache_size`**(mask_cref_type mask, int level) const

Return the size of the cache associated with the given mask.

mask_type **get_cpubind_mask**(*error_code* &ec = *throws*) const

mask_type **get_cpubind_mask**(*std*::thread &handle, *error_code* &ec = *throws*) const

hwloc_bitmap_ptr **cpuset_to_nodeset**(mask_cref_type mask) const

convert a cpu mask into a numa node mask in hwloc bitmap form

void **write_to_log**() const

void ***allocate**(*std*::size_t len) const

This is equivalent to malloc(), except that it tries to allocate page-aligned memory from the OS.

void ***allocate_membind**(*std*::size_t len, *hwloc_bitmap_ptr* const &bitmap, *hpx_hwloc_membind_policy* policy, int flags) const

allocate memory with binding to a numa node set as specified by the policy and flags (see hwloc docs)

threads::mask_type **get_area_membind_nodeset**(void const *addr, *std*::size_t len) const

bool **set_area_membind_nodeset**(void const *addr, *std*::size_t len, void *nodeset) const

int **get_numa_domain**(void const *addr) const

void **deallocate**(void *addr, *std*::size_t len) const noexcept

Free memory that was previously allocated by allocate.

void **print_hwloc**(*std*::ostream&) const

mask_type **init_socket_affinity_mask_from_socket**(*std*::size_t num_socket) const

mask_type **init_numa_node_affinity_mask_from_numa_node**(*std*::size_t num_numa_node) const

mask_type **init_core_affinity_mask_from_core**(*std*::size_t num_core, mask_cref_type default_mask = *empty_mask*) const

mask_type **init_thread_affinity_mask**(*std*::size_t num_thread) const

mask_type **init_thread_affinity_mask**(*std*::size_t num_core, *std*::size_t num_pu) const

hwloc_bitmap_t **mask_to_bitmap**(mask_cref_type mask, hwloc_obj_type_t htype, unsigned *count = nullptr) const

mask_type **bitmap_to_mask**(hwloc_bitmap_t bitmap, hwloc_obj_type_t htype) const

struct **lock_context**

#include <tracing.hpp> Context for annotating lock acquisitions and releases.

This struct is used to provide tracing annotations for synchronization primitives such as spinlocks and mutexes. With HPX_WITH_TRACING_LOCK_EVENTS=ON, it registers the creation, acquisition, and release of locks with the Tracy or ITT backend.

Public Functions

explicit **`lock_context`**`(`char const *name = nullptr, void const *addr = nullptr`)` noexcept

Constructs a lock context.

Parameters

- **`name`** – The name or description of the lock.
- **`addr`** – The memory address of the lock, used to track it uniquely.

explicit **`lock_context`**`(`char const *prefix, char const *suffix, void const *addr = nullptr`)` noexcept

Constructs a lock context with a dynamic name.

Parameters

- **`prefix`** – The prefix for the lock name.
- **`suffix`** – The suffix for the lock name.
- **`addr`** – The memory address of the lock, used to track it uniquely.

bool **`before_lock`**`()` const noexcept

Called immediately before attempting to acquire the lock.

Returns

true if the prepare event was recorded and after_lock should be called.

void **`after_lock`**`()` const noexcept

Called immediately after the lock is successfully acquired.

void **`after_try_lock`**`(`bool success`)` const noexcept

Called after a try-lock operation completes.

Parameters

`success` – true if the lock was acquired, false if it failed.

void **`before_unlock`**`()` const noexcept

Called immediately before releasing the lock.

void **`after_unlock`**`()` const noexcept

Called immediately after releasing the lock.

namespace **`util`**

namespace **`external_timer`**

hpx/tracing/backends/apex.hpp

namespace **`hpx`**

namespace **`tracing`**

Typedefs

`bool(*)() enable_parent_task_handler_type`

typedef char const ***`annotation_handle`**

Functions

inline constexpr *annotation_handle* **`create_annotation_handle`**(char const *name) noexcept

inline constexpr void **`set_thread_name`**(char const *name) noexcept

Set the OS thread name in the profiler timeline.

inline constexpr char const ***`rename_region`**(char const *name) noexcept

Rename the currently active region on this thread; returns the previous name, or the caller's input if no rename occurred.

constexpr void **`task_staged`**(char const*, void const* = nullptr) noexcept

constexpr void **`task_created`**(char const*, void const*, void const* = nullptr) noexcept

constexpr void **`task_executing`**(void const*, char const*, *std*::size_t) noexcept

constexpr void **`task_yielded`**(void const*, char const*) noexcept

constexpr void **`task_suspended`**(void const*, char const*, char const* = nullptr) noexcept

constexpr void **`task_completed`**(void const*, char const*) noexcept

constexpr void **`task_deleted`**(void const*) noexcept

constexpr void **`future_fulfilled`**(void const*, char const* = nullptr) noexcept

Producer-side signal: future state fulfilled (no-op stub for APEX).

Producer-side signal: future state fulfilled (no-op stub).

Producer-side signal: future state fulfilled (no-op stub for ITTNotify).

constexpr void **`future_exception_set`**(void const*, char const* = nullptr) noexcept

Producer-side signal: future exception set (no-op stub for APEX).

Producer-side signal: future exception set (no-op stub).

Producer-side signal: future exception set (no-op stub for ITTNotify).

constexpr void **`continuation_run`**(void const* = nullptr) noexcept

Consumer-side signal: continuation started (no-op stub for APEX).

Consumer-side signal: continuation started (no-op stub).

Consumer-side signal: continuation started (no-op stub for ITTNotify).

constexpr void **continuation_finished**(void const* = nullptr) noexcept

Consumer-side signal: continuation finished (no-op stub for APEX).

Consumer-side signal: continuation finished (no-op stub).

Consumer-side signal: continuation finished (no-op stub for ITTNotify).

constexpr void **handle_on_completed_fired**(void const* = nullptr) noexcept

Consumer-side signal: handle_on_completed fired (no-op stub for APEX).

Consumer-side signal: handle_on_completed fired (no-op stub).

Consumer-side signal: handle_on_completed fired (no-op stub for ITTNotify).

constexpr void **work_stolen**(*std*::size_t, *std*::size_t, void const*, char const* = nullptr) noexcept

Signal emitted when a worker thread steals a task from another worker.

inline constexpr void **frame_mark**(char const* = nullptr) noexcept

Frame boundary marker (no-op stub for APEX).

Frame boundary marker (no-op stub).

Emit a frame/stage boundary marker in Tracy timeline.

Frame boundary marker.

Parameters

name – Optional name for the frame/stage.

inline constexpr void **os_thread_sleep**(*std*::size_t num_thread) noexcept

Point message emitted just before an OS worker thread suspends on its condition variable.

Parameters

num_thread – Index of the worker thread entering sleep.

struct **region_init_data**

struct **loop_context**

inline constexpr bool **valid**() const noexcept

Public Members

std::shared_ptr<*util*::*external_timer*::task_wrapper> **data**

hpx/tracing/backends/ittnotify.hpp

Defined in header hpx/tracing/backends/ittnotify.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **tracing**

Functions

task_timer_data **create_task_timer**(*threads*::*thread_description* const &description, *std*::uint32_t parent_locality_id, *threads*::*thread_id* const &parent_task)

void **update_task_timer**(*task_timer_data* &timer, char const *new_name)

void **tracing_finalize**()

inline void **register_thread**(char const *name)

inline void **send_parcel**(*std*::uint64_t tag_msb, *std*::uint64_t tag_lsb, *std*::uint64_t size, *std*::uint64_t target_locality_id) noexcept

Parcel-send signal: parcel handed to parcelport (APEX shim).

Parcel-send signal: parcel handed to parcelport (no-op stub).

Parcel-send signal: a parcel has been handed to the parcelport for transmission.

Parcel-send signal: parcel handed to parcelport (no-op stub for ITTNotify).

Parameters

- **tag_msb** – High 64 bits of the parcel id.
- **tag_lsb** – Low 64 bits of the parcel id. Together with tag_msb they form the full 128-bit id used to pair events across localities; lsb alone restarts per locality and would produce false matches.
- **size** – Wire size of the parcel in bytes.
- **target_locality_id** – Destination locality id, or `naming::invalid_locality_id` if unknown.

inline void **recv_parcel**(*std*::uint64_t tag_msb, *std*::uint64_t tag_lsb, *std*::uint64_t source_locality_id) noexcept

Parcel-receive signal: parcel arrived (APEX shim).

Parcel-receive signal: parcel arrived (no-op stub).

Parcel-receive signal: a parcel has arrived and its header has been deserialized.

Parcel-receive signal: parcel arrived (no-op stub for ITTNotify).

Parameters

- **tag_msb** – High 64 bits of the parcel id.

- **`tag_lsb`** – Low 64 bits of the parcel id.
- **`source_locality_id`** – Sending locality id, or `naming::invalid_locality_id` when the parcel has no source id yet (pre-AGAS handshake parcels).

inline void **`parcel_scheduled`**(*std*::uint64_t tag_msb, *std*::uint64_t tag_lsb, *std*::uint64_t source_locality_id, *std*::uint64_t source_thread_id) noexcept

Parcel-scheduled signal: action entered local scheduler (no-op stub for APEX).

Parcel-scheduled signal: action entered local scheduler (no-op stub).

Parcel-scheduled signal: an action carried by a parcel has been placed onto the local scheduler. Fires for deferred receives (zero-copy or multi-parcel message), for AGAS-routed parcels, and for parcels the AGAS re-route chain delivered after a migration detection. Does not fire for the non-deferred path where load_schedule schedules inline.

Parcel-scheduled signal: action entered local scheduler (no-op stub for ITTNotify).

Parameters

- **`tag_msb`** – High 64 bits of the parcel id.
- **`tag_lsb`** – Low 64 bits of the parcel id.
- **`source_locality_id`** – Sending locality id (see recv_parcel).
- **`source_thread_id`** – Parent HPX thread id captured on the sender; may be 0 when unavailable.

namespace **`hpx`**

namespace **`util`**

Functions

bool **parse_sed_expression**(*std*::string const &input, *std*::string &search, *std*::string &replace)

Parse a sed command.

> **Note**
>
> Currently, only supports search and replace syntax (s/search/replace/)

Parameters

- **input** – [in] The content to parse.
- **search** – [out] If the parsing is successful, this string is set to the search expression.
- **replace** – [out] If the parsing is successful, this string is set to the replace expression.

Returns

true if the parsing was successful, false otherwise.

struct **sed_transform**

#include <sed_transform.hpp> An unary function object which applies a sed command to its subject and returns the resulting string.

> **Note**
>
> Currently, only supports search and replace syntax (s/search/replace/)

Public Functions

namespace **hpx**

namespace **util**

Functions

template<typename **Iterator**>
constexpr bool **insert_checked**(*std*::pair<*Iterator*, bool> const &r) noexcept

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.

Parameters

r – [in] The return value of a std::map insert operation.

Returns

This function returns **r.second**.

template<typename **Iterator**>
bool **insert_checked**(*std*::pair<*Iterator*, bool> const &r, *Iterator* &it)

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.

Parameters

- **r** – [in] The return value of a std::map insert operation.
- **r** – [out] A reference to an Iterator, which is set to **r.first**.
- **it** – [out] on exit, will hold the iterator referring to the inserted element

Returns

This function returns **r.second**.

hpx/actions_base/reflect_annotated_actions.hpp

Defined in header hpx/actions_base/reflect_annotated_actions.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Annotation-driven HPX action registration via C++26 reflection.

Functions decorated with [[=hpx::actions::detail::remote_function{}]] are automatically discovered and registered as HPX plain actions.

Usage:

```
namespace my_app {
    [[=hpx::actions::detail::remote_function{}]]
    int compute(int x) { return x + 1; }
}
HPX_REGISTER_ANNOTATED_ACTIONS(my_app)

\warning This macro must be invoked after all annotated function
definitions in \a Ns are complete. Since C++ namespaces are open,
functions added to \a Ns after this macro is expanded will NOT be
discovered or registered.

// Then dispatch via:
hpx::async<hpx::actions::reflect_action<^^my_app::compute>>(id, 42);
```

namespace **hpx**

namespace **actions**

hpx/actions_base/lambda_to_action.hpp

Defined in header hpx/actions_base/lambda_to_action.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/actions_base/basic_action_fwd.hpp

Defined in header hpx/actions_base/basic_action_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **actions**

hpx/actions_base/macros.hpp

Defined in header hpx/actions_base/macros.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Defines

HPX_REGISTER_ACTION_INVOCATION_COUNT(Action)

HPX_REGISTER_PER_ACTION_DATA_COUNTER_TYPES(Action)

HPX_MAKE_ACTION(func)

HPX_MAKE_DIRECT_ACTION(func)

HPX_DECLARE_ACTION(...)

Declares an action type.

HPX_REGISTER_ACTION_DECLARATION(...)

Declare the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION_DECLARATION* can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to declare the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server,
            print_greeting, print_greeting_action);
    };
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action)
```

Example:

Note

This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* macros. It has to be visible in all translation units using the action, thus it is recommended to place it into the header file defining the component.

HPX_REGISTER_ACTION_DECLARATION_(...)

HPX_REGISTER_ACTION_DECLARATION_1(action)

HPX_REGISTER_ACTION(...)

Define the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.

Note

This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* or *HPX_DEFINE_PLAIN_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note

Only one of the forms of this macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID* should be used for a particular action, never both.

`HPX_REGISTER_ACTION_ID`(action, actionname, actionid)

Define the necessary component action boilerplate code and assign a predefined unique id to the action.

The macro *HPX_REGISTER_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

The parameter *actionname* specifies a unique name of the action to be used for serialization purposes. The second parameter has to be usable as a plain (nonqualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.

The parameter *actionid* specifies a unique integer value which will be used to represent the action during serialization.

Note

This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* or global actions *HPX_DEFINE_PLAIN_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note

Only one of the forms of this macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID* should be used for a particular action, never both.

`HPX_DEFINE_COMPONENT_ACTION`(...)

Registers a member function of a component as an action type with HPX.

The macro *HPX_DEFINE_COMPONENT_ACTION* can be used to register a member function of a component as an action type named *action_type*.

The parameter *component* is the type of the component exposing the member function *func* which should be associated with the newly defined action type. The parameter `action_type` is the name of the action type to register with HPX.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting() const
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting,
            print_greeting_action);
    };
}
```

Example:

The first argument must provide the type name of the component the action is defined for.

The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending '_action'. The third argument can be omitted only if the second argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name.

Note

The macro *HPX_DEFINE_COMPONENT_ACTION* can be used with 2 or 3 arguments. The third argument is optional.

`HPX_DEFINE_PLAIN_ACTION`(...)

Defines a plain action type.

```
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // This will define the action type 'app::some_global_action' which
    // represents the function 'app::some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
```

Example:

Note

Usually this macro will not be used in user code unless the intent is to avoid defining the action_type in global namespace. Normally, the use of the macro *HPX_PLAIN_ACTION* is recommended.

Note

The macro *HPX_DEFINE_PLAIN_ACTION* can be used with 1 or 2 arguments. The second argument is optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name.

`HPX_DECLARE_PLAIN_ACTION`(...)

Declares a plain action type.

`HPX_PLAIN_ACTION`(...)

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX_PLAIN_ACTION* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *name* representing the given function. This macro additionally registers the newly define action type with HPX.

The parameter `func` is a global or free (non-member) function which should be encapsulated into a plain action. The parameter `name` is the name of the action type defined by this macro.

```
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which
// represents the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action)
```

Example:

Note

The macro *HPX_PLAIN_ACTION* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

Note

The macro *HPX_PLAIN_ACTION_ID* can be used with 1, 2, or 3 arguments. The second and third arguments are optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name. The default value for the third argument is *hpx::components::factory_state::check*.

Note

Only one of the forms of this macro *HPX_PLAIN_ACTION* or *HPX_PLAIN_ACTION_ID* should be used for a particular action, never both.

HPX_PLAIN_ACTION_ID(func, name, id)

Defines a plain action type based on the given function *func* and registers it with HPX.

The macro *HPX_PLAIN_ACTION_ID* can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function *func*. It defines the action type *actionname* representing the given function.

The parameter *actionid* specifies a unique integer value which will be used to represent the action during serialization.

The parameter `func` is a global or free (non-member) function which should be encapsulated into a plain action. The parameter `name` is the name of the action type defined by this macro.

The second parameter has to be usable as a plain (nonqualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which
// represents the function 'app::some_global_function'.
HPX_PLAIN_ACTION_ID(app::some_global_function, some_global_action,
    some_unique_id);
```

Example:

Note

The macro *HPX_PLAIN_ACTION_ID* has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

Note

Only one of the forms of this macro *HPX_PLAIN_ACTION* or *HPX_PLAIN_ACTION_ID* should be used for a particular action, never both.

HPX_REGISTER_ACTION_FACTORY_ID(Name, Id)

HPX_DEFINE_COMPONENT_ACTION

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

HPX_DEFINE_COMPONENT_ACTION(...)

Registers a member function of a component as an action type with HPX.

The macro *HPX_DEFINE_COMPONENT_ACTION* can be used to register a member function of a component as an action type named *action_type*.

The parameter *component* is the type of the component exposing the member function *func* which should be associated with the newly defined action type. The parameter `action_type` is the name of the action type to register with HPX.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting() const
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting,
            print_greeting_action);
    };
}
```

Example:

The first argument must provide the type name of the component the action is defined for.

The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending '_action'. The third argument can be omitted only if the second argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name.

Note

The macro *HPX_DEFINE_COMPONENT_ACTION* can be used with 2 or 3 arguments. The third argument is optional.

HPX_REGISTER_ACTION_DECLARATION

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *HPX_REGISTER_ACTION*

HPX_REGISTER_ACTION_DECLARATION(...)

Declare the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION_DECLARATION* can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to declare the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
      : public hpx::components::component_base<server>
    {
        void print_greeting ()
        {
            hpx::cout << "Hey, how are you?\n" << std::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server,
            print_greeting, print_greeting_action);
    };
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action)
```

Example:

Note

This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* macros. It has to be visible in all translation units using the action, thus it is recommended to place it into the header file defining the component.

HPX_REGISTER_ACTION

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *HPX_REGISTER_ACTION_DECLARATION*

`HPX_REGISTER_ACTION`(...)

Define the necessary component action boilerplate code.

The macro *HPX_REGISTER_ACTION* can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter *action* is the type of the action to define the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (nonqualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

Note

This macro has to be used once for each of the component actions defined using one of the *HPX_DEFINE_COMPONENT_ACTION* or *HPX_DEFINE_PLAIN_ACTION* macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note

Only one of the forms of this macro *HPX_REGISTER_ACTION* or *HPX_REGISTER_ACTION_ID* should be used for a particular action, never both.

hpx/actions_base/reflect_action.hpp

Defined in header hpx/agas/addressing_service.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **agas**

struct **addressing_service**

Public Types

enum class **resolved_locality_state** : *std*::uint8_t

How a locality became known to this instance, which decides whether hpx::force_disconnect may remove it.

Values:

enumerator **connected**

Started with the application, or learned about by resolving its address. hpx::force_disconnect rejects it.

enumerator **connecting**

Connected after the application started and registered as such here, which only the console does. hpx::force_disconnect accepts it.

enumerator **disconnecting**

Claimed by an hpx::force_disconnect call that is still removing it. Further claims are rejected until the entry is erased.

using **component_id_type** = *components*::*component_type* using **iterate_names_return_type** = *std*::map<*std*::string, *hpx*::*id_type*>

void **register_console**(*parcelset*::endpoints_type const &eps)

inline bool **is_bootstrap**() const

inline bool **is_console**() const

Returns whether this *addressing_service* represents the console locality.

inline bool **is_connecting**() const

Returns whether this *addressing_service* is connecting to a running application.

bool **is_connecting**(*hpx*::*naming*::*gid_type* const &locality) const

Return whether a locality joined while connecting.

Parameters

`locality` – The locality GID to inspect. If locality is invalid, return the connecting status of the calling locality.

Returns

`true` if the locality connected late, also while it is being removed and after it was disconnected, and `false` for a locality that started with the application.

bool **mark_connecting_locality_as_disconnecting**(*hpx*::*naming*::*gid_type* const &locality)

Atomically claim a connecting locality for disconnection.

Parameters

`locality` – The locality GID to claim.

Returns

`true` if this call changed the locality state from connecting to disconnecting, and `false` otherwise.

bool **mark_disconnecting_locality_as_connecting**(*hpx*::*naming*::*gid_type* const &locality)

Release a claim made by mark_connecting_locality_as_disconnecting.

Parameters

`locality` – The locality GID to release.

Returns

`true` if this call changed the locality state from disconnecting back to connecting, and `false` otherwise.

bool **resolve_locally_known_addresses**(*naming*::*gid_type* const &id, *naming*::*address* &addr) const

bool **register_locality**(*parcelset*::endpoints_type const &endpoints, *naming*::*gid_type* &prefix, *std*::uint32_t num_threads, bool is_connecting, *error_code* &ec = *throws*)

Add a locality to the runtime.

parcelset::endpoints_type const &**resolve_locality**(*naming*::*gid_type* const &gid, *error_code* &ec = *throws*)

Resolve a locality to its prefix.

Returns

Returns an empty vector if the locality is not registered.

bool **has_resolved_locality**(*naming*::*gid_type* const &gid) const

bool **unregister_locality**(*naming*::*gid_type* const &gid, *error_code* &ec = *throws*)

Remove a locality from the runtime.

void **remove_resolved_locality**(*naming*::*gid_type* const &gid)

remove given locality from locality cache

bool **get_console_locality**(*naming*::*gid_type* &locality, *error_code* &ec = *throws*)

Get locality locality_id of the console locality.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`locality`** – [out] The locality_id value uniquely identifying the console locality. This is valid only, if the return value of this function is true.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a console locality_id exists and returns *false* otherwise.

bool **get_localities**(*std*::vector<*naming*::*gid_type*> &locality_ids, *components*::*component_type* type, *error_code* &ec = *throws*) const

Query for the locality_ids of all known localities.

This function returns the locality_ids of all localities known to the AGAS server or all localities having a registered factory for a given component type.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- `locality_ids` – [out] The vector will contain the prefixes of all localities registered with the AGAS server. The returned vector holds the prefixes representing the runtime_support components of these localities.
- `type` – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_enum_type::invalid*, which will return prefixes of all localities.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline bool **`get_localities`**(*std*::vector<*naming*::*gid_type*> &locality_ids, *error_code* &ec = *throws*) const

hpx::*future*<*std*::uint32_t> **`get_num_localities_async`**(*components*::*component_type* type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*)) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

Parameters

`type` – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_type::invalid*, which will return prefixes of all localities.

Returns

A future that becomes ready with the number of matching localities.

std::uint32_t **`get_num_localities`**(*components*::*component_type* type, *error_code* &ec = *throws*) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- `type` – [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is *components::component_type::invalid*, which will return prefixes of all localities.

- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

inline *std*::uint32_t **`get_num_localities`**(*error_code* &ec = *throws*) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<*std*::uint32_t> **`get_num_overall_threads_async`**() const

std::uint32_t **`get_num_overall_threads`**(*error_code* &ec = *throws*) const

hpx::*future*<*std*::vector<*std*::uint32_t>> **`get_num_threads_async`**() const

std::vector<*std*::uint32_t> **`get_num_threads`**(*error_code* &ec = *throws*) const

components::*component_type* **`get_component_id`**(*std*::string const &name, *error_code* &ec = *throws*) const

Return a unique id usable as a component type.

This function returns the component type id associated with the given component name. If this is the first request for this component name a new unique id will be created.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`name`** – [in] The component name (string) to get the component type for.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns the currently associated component type. Any error results in an exception thrown from this function.

void **`iterate_types`**(*iterate_types_function_type* const &f, *error_code* &ec = *throws*) const

std::string **`get_component_type_name`**(*components*::*component_type* id, *error_code* &ec = *throws*) const

inline *components*::*component_type* **`register_factory`**(*naming*::*gid_type* const &locality_id, *std*::string const &name, *error_code* &ec = *throws*) const

Register a factory for a specific component type.

This function allows to register a component factory for a given locality and component type.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`locality_id`** – [in] The locality value uniquely identifying the given locality the factory needs to be registered for.
- **`name`** – [in] The component name (string) to register a factory for the given component type for.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns the currently associated component type. Any error results in an exception thrown from this function. The returned component type is the same as if the function *get_component_id* was called using the same component name.

components::*component_type* **`register_factory`**(*std*::uint32_t locality_id, *std*::string const &name, *error_code* &ec = *throws*) const

bool **`get_id_range`**(*std*::uint64_t count, *naming*::*gid_type* &lower_bound, *naming*::*gid_type* &upper_bound, *error_code* &ec = *throws*)

Get unique range of freely assignable global ids.

Every locality needs to be able to assign global ids to different components without having to consult the AGAS server for every id to generate. This function can be called to preallocate a range of ids usable for this purpose.

Note

This function assigns a range of global ids usable by the given locality for newly created components. Any of the returned global ids still has to be bound to a local address, either by calling *bind* or *bind_range*.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`count`** – [in] The number of global ids to be generated.
- **`lower_bound`** – [out] The lower bound of the assigned id range. The returned value can be used as the first id to assign. This is valid only, if the return value of this function is true.
- **`upper_bound`** – [out] The upper bound of the assigned id range. The returned value can be used as the last id to assign. This is valid only, if the return value of this function is true.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

inline bool **`bind_local`**(*naming*::*gid_type* const &id, *naming*::*address* const &addr, *error_code* &ec = *throws*)

Bind a global address to a local address.

Every element in the HPX namespace has a unique global address (global id). This global address has to be associated with a concrete local address to be able to address an instance of a component using its global address.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> Binding a gid to a local address sets its global reference count to one.

Parameters

- **`id`** – [in] The global address which has to be bound to the local address.
- **`addr`** – [in] The local address to be bound to the global address.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true*, if this global id got associated with an local address. It returns *false* otherwise.

inline *hpx*::*future*<bool> **`bind_async`**(*naming*::*gid_type* const &id, *naming*::*address* const &addr, *std*::uint32_t locality_id)

inline *hpx*::*future*<bool> **`bind_async`**(*naming*::*gid_type* const &id, *naming*::*address* const &addr, *naming*::*gid_type* const &locality)

bool **`bind_range_local`**(*naming*::*gid_type* const &lower_id, *std*::uint64_t count, *naming*::*address* const &baseaddr, *std*::uint64_t offset, *error_code* &ec = *throws*)

Bind unique range of global ids to given base address.

Every locality needs to be able to bind global ids to different components without having to consult the AGAS server for every id to bind. This function can be called to bind a range of consecutive global ids to a range of consecutive local addresses (separated by a given *offset*).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note

Binding a gid to a local address sets its global reference count to one.

Parameters

- **`lower_id`** – [in] The lower bound of the assigned id range. The value can be used as the first id to assign.
- **`count`** – [in] The number of consecutive global ids to bind starting at *lower_id*.
- **`baseaddr`** – [in] The local address to bind to the global id given by *lower_id*. This is the base address for all additional local addresses to bind to the remaining global ids.
- **`offset`** – [in] The offset to use to calculate the local addresses to be bound to the range of global ids.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true*, if the given range was successfully bound. It returns *false* otherwise.

hpx::*future*<bool> **`bind_range_async`**(*naming*::*gid_type* const &lower_id, *std*::uint64_t count, *naming*::*address* const &baseaddr, *std*::uint64_t offset, *naming*::*gid_type* const &locality)

inline *hpx*::*future*<bool> **`bind_range_async`**(*naming*::*gid_type* const &lower_id, *std*::uint64_t count, *naming*::*address* const &baseaddr, *std*::uint64_t offset, *std*::uint32_t locality_id)

inline bool **`unbind_local`**(*naming*::*gid_type* const &id, *error_code* &ec = *throws*)

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

Note

You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind_range*.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note

This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **`id`** – [in] The global address (id) for which the association has to be removed.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

inline bool **`unbind_local`**(*naming*::*gid_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*)

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

> **Note**
>
> You can unbind only global ids bound using the function *bind*. Do not use this function to unbind any of the global ids bound using *bind_range*.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **`id`** – [in] The global address (id) for which the association has to be removed.
- **`addr`** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

inline bool **`unbind_range_local`**(*naming*::*gid_type* const &lower_id, *std*::uint64_t count, *error_code* &ec = *throws*)

Unbind the given range of global ids.

> **Note**
>
> You can unbind only global ids bound using the function *bind_range*. Do not use this function to unbind any of the global ids bound using *bind*.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **`lower_id`** – [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to *bind_range*.
- **`count`** – [in] The number of consecutive global ids to unbind starting at *lower_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind_range*
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

bool **`unbind_range_local`**(*naming*::*gid_type* const &lower_id, *std*::uint64_t count, *naming*::*address* &addr, *error_code* &ec = *throws*)

Unbind the given range of global ids.

> **Note**
>
> You can unbind only global ids bound using the function *bind_range*. Do not use this function to unbind any of the global ids bound using *bind*.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- **`lower_id`** – [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to *bind_range*.
- **`count`** – [in] The number of consecutive global ids to unbind starting at *lower_id*. This number must be identical to the number of global ids bound by the corresponding call to *bind_range*
- **`addr`** – [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if a new range has been generated (it has been called for the first time for the given locality) and returns *false* if this locality already got a range assigned in an earlier call.

hpx::*future*<*naming*::*address*> **`unbind_range_async`**(*naming*::*gid_type* const &lower_id, *std*::uint64_t count = 1)

inline bool **`is_local_address_cached`**(*naming*::*gid_type* const &id, *error_code* &ec = *throws*)

Test whether the given address refers to a local object.

This function will test whether the given address refers to an object living on the locality of the caller.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The address to test.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if the passed address refers to an object which lives on the locality of the caller.

bool **`is_local_address_cached`**(*naming*::*gid_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*)

bool **`is_local_address_cached`**(*naming*::*gid_type* const &id, *naming*::*address* &addr, *std*::pair<bool, *components*::pinned_ptr> &r, *hpx*::*move_only_function*<*std*::pair<bool, *components*::pinned_ptr>(*naming*::*address* const&)> &&f, *error_code* &ec = *throws*)

bool **`is_local_lva_encoded_address`**(*std*::uint64_t msb) const

inline bool **`resolve_local`**(*naming*::*gid_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*)

Resolve a given global address (*id*) to its associated local address.

This function returns the local address which is currently associated with the given global address (*id*).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The global address (*id*) for which the associated local address should be returned.
- **`addr`** – [out] The local address which currently is associated with the given global address (id), this is valid only if the return value of this function is true.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns *true* if the global address has been resolved successfully (there exists an association to a local address) and the associated local address has been returned. The function returns *false* if no association exists for the given global address. Any error results in an exception thrown from this function.

inline bool **`resolve_local`**(*hpx*::*id_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*)

inline *naming*::*address* **`resolve_local`**(*naming*::*gid_type* const &id, *error_code* &ec = *throws*)

inline *naming*::*address* **`resolve_local`**(*hpx*::*id_type* const &id, *error_code* &ec = *throws*)

hpx::future_or_value<*naming*::*address*> **`resolve_async`**(*naming*::*gid_type* const &id)

inline *hpx*::future_or_value<*naming*::*address*> **`resolve_async`**(*hpx*::*id_type* const &id)

hpx::future_or_value<*id_type*> **`get_colocation_id_async`**(*hpx*::*id_type* const &id)

bool **`resolve_full_local`**(*naming*::*gid_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*)

inline bool **`resolve_full_local`**(*hpx*::*id_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*)

inline *naming*::*address* **`resolve_full_local`**(*naming*::*gid_type* const &id, *error_code* &ec = *throws*)

inline *naming*::*address* **`resolve_full_local`**(*hpx*::*id_type* const &id, *error_code* &ec = *throws*)

hpx::future_or_value<*naming*::*address*> **`resolve_full_async`**(*naming*::*gid_type* const &id)

inline *hpx*::future_or_value<*naming*::*address*> **`resolve_full_async`**(*hpx*::*id_type* const &id)

bool **`resolve_cached`**(*naming*::*gid_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*) const

inline bool **`resolve_cached`**(*hpx*::*id_type* const &id, *naming*::*address* &addr, *error_code* &ec = *throws*)

inline bool **`resolve_local`**(*naming*::*gid_type* const *gids, *naming*::*address* *addrs, *std*::size_t size, *hpx*::detail::dynamic_bitset<> &locals, *error_code* &ec = *throws*)

bool **`resolve_full_local`**(*naming*::*gid_type* const *gids, *naming*::*address* *addrs, *std*::size_t size, *hpx*::detail::dynamic_bitset<> &locals, *error_code* &ec = *throws*)

bool **`resolve_cached`**(*naming*::*gid_type* const *gids, *naming*::*address* *addrs, *std*::size_t size, *hpx*::detail::dynamic_bitset<> &locals, *error_code* &ec = *throws*) const

hpx::future_or_value<*std*::int64_t> **`incref_async`**(*naming*::*gid_type* const &gid, *std*::int64_t credits = 1, *hpx*::*id_type* const &keep_alive = *hpx*::invalid_id)

Increment the global reference count for the given id.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`gid`** – [in] The global address (id) for which the global reference count has to be incremented.
- **`credits`** – [in] The number of reference counts to add for the given id.
- **`keep_alive`** – [in] Id to keep alive (if valid)

Returns

Whether the operation was successful.

inline *std*::int64_t **`incref`**(*naming*::*gid_type* const &gid, *std*::int64_t credits = 1, *error_code* &ec = *throws*)

void **`decref`**(*naming*::*gid_type* const &id, *std*::int64_t credits = 1, *error_code* &ec = *throws*)

Decrement the global reference count for the given id.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`id`** – [in] The global address (id) for which the global reference count has to be decremented.
- **`credits`** – [in] The number of reference counts to add for the given id.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global reference count after the decrement.

hpx::*future*<*iterate_names_return_type*> **`iterate_ids`**(*std*::string const &pattern) const

Invoke the supplied *hpx::function* for every registered global name.

This function iterates over all registered global ids and returns every found entry matching the given name pattern. Any error results in an exception thrown (or reported) from this function.

Parameters

`pattern` – [in] pattern (possibly using wildcards) to match all existing entries against

bool **`register_name`**(*std*::string const &name, *naming*::*gid_type* const &id, *error_code* &ec = *throws*) const

Register a global name with a global address (id)

This function registers an association between a global name (string) and a global address (id) usable with one of the functions above (bind, unbind, and resolve).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`name`** – [in] The global name (string) to be associated with the global address.
- **`id`** – [in] The global address (id) to be associated with the global address.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The function returns *true* if the global name was registered. It returns false if the global name is not registered.

hpx::*future*<bool> **`register_name_async`**(*std*::string const &name, *hpx*::*id_type* const &id) const

bool **`register_name`**(*std*::string const &name, *hpx*::*id_type* const &id, *error_code* &ec = *throws*) const

hpx::*future*<*hpx*::*id_type*> **`unregister_name_async`**(*std*::string const &name) const

Unregister a global name (release any existing association).

This function releases any existing association of the given global name with a global address (id).

Parameters

`name` – [in] The global name (string) for which any association with a global address (id) has to be released.

Returns

A future that becomes ready with the global id that was associated with the given name.

hpx::*id_type* **`unregister_name`**(*std*::string const &name, *error_code* &ec = *throws*) const

Unregister a global name (release any existing association)

This function releases any existing association of the given global name with a global address (id).

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`name`** – [in] The global name (string) for which any association with a global address (id) has to be released.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id that was associated with the given name. Any error results in an exception thrown from this function.

hpx::*future*<*hpx*::*id_type*> **`resolve_name_async`**(*std*::string const &name) const

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

Parameters

`name` – [in] The global name (string) for which the currently associated global address has to be retrieved.

Returns

A future holding the global id currently associated with the given global name.

hpx::*id_type* **`resolve_name`**(*std*::string const &name, *error_code* &ec = *throws*) const

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- `name` – [in] The global name (string) for which the currently associated global address has to be retrieved.
- `ec` – [in,out] This represents the error status on exit. If this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id currently associated with the given global name.

future<*hpx*::*id_type*> **`on_symbol_namespace_event`**(*std*::string const &name, bool call_for_past_events = false) const

Install a listener for a given symbol namespace event.

This function installs a listener for a given symbol namespace event. It returns a future which becomes ready as a result of the listener being triggered.

Note

The only event type which is currently supported is *symbol_ns_bind*, i.e. the listener is triggered whenever a global id is registered with the given name.

Parameters

- `name` – [in] The global name (string) for which the given event should be triggered.
- `call_for_past_events` – [in, optional] Trigger the listener even if the given event has already happened in the past. The default for this parameter is *false*.

Returns

A future instance encapsulating the global id which is causing the registered listener to be triggered.

void **`update_cache_entry`**(*naming*::*gid_type* const &gid, *gva* const &gva, *error_code* &ec = *throws*)

Warning

This function is for internal use only. It is dangerous and may break your code if you use it.

inline void **`update_cache_entry`**(*naming*::*gid_type* const &gid, *naming*::*address* const &addr, *std*::uint64_t count = 0, *std*::uint64_t offset = 0, *error_code* &ec = *throws*)

Warning

This function is for internal use only. It is dangerous and may break your code if you use it.

bool **`get_cache_entry`**(*naming*::*gid_type* const &gid, *gva* &gva, *naming*::*gid_type* &idbase, *error_code* &ec = *throws*) const

Warning

This function is for internal use only. It is dangerous and may break your code if you use it.

void **remove_cache_entry**(*naming*::*gid_type* const &id, *error_code* &ec = *throws*) const

> **Warning**
>
> This function is for internal use only. It is dangerous and may break your code if you use it.

void **clear_cache**(*error_code* &ec = *throws*) const

> **Warning**
>
> This function is for internal use only. It is dangerous and may break your code if you use it.

void **start_shutdown**(*error_code* &ec = *throws*)

hpx::*future*<*std*::pair<*hpx*::*id_type*, *naming*::*address*>> **begin_migration**(*hpx*::*id_type* const &id)

start/stop migration of an object

Returns

Current locality and address of the object to migrate

bool **end_migration**(*hpx*::*id_type* const &id)

std::pair<bool, *components*::pinned_ptr> **was_object_migrated**(*naming*::*gid_type* const &gid, *hpx*::*move_only_function*<*components*::pinned_ptr &&f) const

Check whether an object is marked as having migrated away.

std::pair<bool, *components*::pinned_ptr> **was_object_migrated**(*naming*::*gid_type* const &gid, *naming*::address_type lva, *hpx*::*move_only_function*<*components*::pinned_ptr &&f) const

Check the supplied LVA against the local migration state.

hpx::*future*<void> **mark_as_migrated**(*naming*::*gid_type* const &gid, *hpx*::*move_only_function*<*std*::pair<bool, *hpx*::*future*<void>>()> &&f, bool expect_to_be_marked_as_migrating)

Mark the given object as being migrated (if the object is unpinned). Delay migration until the object is unpinned otherwise.

void **unmark_as_migrated**(*naming*::*gid_type* const &gid, *hpx*::*move_only_function*<void()> &&f)

Remove an object's migration record when its LVA is unavailable.

void **unmark_as_migrated**(*naming*::*gid_type* const &gid_, *naming*::address_type lva, *hpx*::*move_only_function*<void()> &&f)

Record the current LVA of an object which is resident again.

void **pre_cache_endpoints**(*std*::vector<*parcelset*::endpoints_type> const&)

Public Members

agas_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/agas_base/agas_fwd.hpp

Defined in header hpx/agas_base/agas_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **agas**

Typedefs

using **iterate_types_function_type** = *hpx*::*function*<void(*std*::string const&, *components*::*component_type*), true>

Functions

std::string **service_name_prefix**()

Returns *service_name* with the id of the locality hosting the AGAS services substituted, i.e. "/0/agas/" unless this locality is connecting to a running application.

std::string **service_instance_name**(char const *servicename, char const *namespace_service_name)

Returns the name one AGAS namespace service is registered under: the prefix returned by *service_name_prefix* followed by *servicename* and the service name of the namespace itself (one of agas::server::primary_namespace_service_name and friends).

hpx::chrono::*steady_duration* **get_rpc_timeout**() noexcept

Get the currently configured timeout for AGAS RPC operations.

bool **`set_rpc_timeout`**(*hpx*::chrono::*steady_duration* const &timeout) noexcept

Set the timeout for AGAS RPC operations.

Parameters

`timeout` – The new duration for AGAS RPC timeouts.

Returns

true if timeout is strictly positive and set successfully, false otherwise.

Variables

constexpr char const *const **`service_name`** = "/{}/agas/"

constexpr *std*::uint64_t **`locality_ns_lsb`** = 0x000000004ULL

namespace **`server`**

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

```
|-----MSB------||------LSB-----|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|

MSB        - Most significant bits (bit 64 to bit 127)
LSB        - Least significant bits (bit 0 to bit 63)
prefix     - Highest 32 bits (bit 96 to bit 127) of the MSB. Each
             locality is assigned a prefix. This creates a 96-bit
             address space for each locality.
RC         - Bit 88 to bit 92 of the MSB. This is the log2 of the number
             of reference counting credits on the GID.
```

(continues on next page)

(continued from previous page)

```
             Bit 93 is used by the locking scheme for gid_types.
             Bit 94 is a flag which is set if the credit value is valid.
             Bit 95 is a flag that is set if a GID's credit count is
             ever split (e.g. if the GID is ever passed to another
             locality).
           - Bit 87 marks the gid such that it will not be stored in
             any of the AGAS caches. This is used mainly for ids
             which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The
             content of these bits depends on the component type of
             the underlying object. For all user-defined components,
             these bits contain a unique 88-bit number which is
             assigned sequentially for each locality. For
             \a hpx#components#component_enum_type#runtime_support
             the high 24 bits are zeroed and the low 64 bits hold the
             LVA of the component.
```

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxx
    Historically unused address space reserved for future use.
xxxxxxxxxxxx0000xxxxxxxxxxxxxxxx
    Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxx
    Prefix of the bootstrap AGAS locality.
00000001000000010000000000000001
    Address of the primary_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000002
    Address of the component_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000003
    Address of the symbol_namespace component on the bootstrap AGAS
    locality.
00000001000000010000000000000004
    Address of the locality_namespace component on the bootstrap AGAS
    locality.
```

Note

The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

async_colocated

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/async_colocated/async_colocated_fwd.hpp

Defined in header hpx/async_colocated/async_colocated_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::get_colocation_id

Defined in header hpx/runtime.hpp[1011].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::*id_type* **hpx::get_colocation_id**(*launch*::sync_policy, *hpx*::*id_type* const &id, *error_code* &ec = *throws*)

Return the id of the locality where the object referenced by the given id is currently located on.

The function *hpx::get_colocation_id()* returns the id of the locality where the given object is currently located.

See also

hpx::get_colocation_id()

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Parameters

[1011] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

- **`id`** – [in] The id of the object to locate.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::*future*<*hpx*::*id_type*> `hpx::get_colocation_id`(*hpx*::*id_type* const &id)

Asynchronously return the id of the locality where the object referenced by the given id is currently located on.

See also

hpx::get_colocation_id(launch::sync_policy)

Parameters

`id` – [in] The id of the object to locate.

hpx/async_colocated/post_colocated_callback_fwd.hpp

Defined in header hpx/async_colocated/post_colocated_callback_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/async_colocated/post_colocated_fwd.hpp

Defined in header hpx/async_colocated/post_colocated_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/async_colocated/async_colocated_callback_fwd.hpp

Defined in header hpx/async_colocated/async_colocated_callback_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

async_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`components`**

namespace **lcos**

template<typename **Result**, typename **RemoteResult**, typename **ComponentTag**>

class **base_lco_with_value** : public *hpx*::*lcos*::*base_lco*, public *ComponentTag*

#include <base_lco_with_value.hpp> The base_lco_with_value class is the common base class for all LCO's synchronizing on a value. The *RemoteResult* template argument should be set to the type of the argument expected for the set_value action.

Template Parameters

- **RemoteResult** – The type of the result value to be carried back to the LCO instance.
- **ComponentTag** – The tag type representing the type of the component (either component_tag or managed_component_tag).

Public Types

using **wrapping_type** = detail::base_lco_wrapping_type<*ComponentTag*, *base_lco_with_value*>::type

using **base_type_holder** = *base_lco_with_value*

Public Functions

inline void **set_value_nonvirt**(*RemoteResult* &&result)

The *function* set_value_nonvirt is called whenever a *set_value_action* is applied on this LCO instance. This function just forwards to the virtual function *set_value*, which is overloaded by the derived concrete LCO.

Parameters

result – [in] The result value to be transferred from the remote operation back to this LCO instance.

inline *Result* **get_value_nonvirt**()

The *function* get_result_nonvirt is called whenever a *get_result_action* is applied on this LCO instance. This function just forwards to the virtual function *get_result*, which is overloaded by the derived concrete LCO.

Public Static Functions

static inline *components*::*component_type* **get_component_type**() noexcept

static inline void **set_component_type**(*components*::*component_type* type)

Protected Types

using **result_type** = *std*::conditional_t<*std*::is_void_v<*Result*>, *util*::unused_type, *Result*>

Protected Functions

~base_lco_with_value() override = default

Destructor, needs to be virtual to allow for clean destruction of derived objects

inline virtual void **set_event**() override

virtual void **set_value**(*RemoteResult* &&result) = 0

virtual *result_type* **get_value**() = 0

inline virtual *result_type* **get_value**(*error_code*&)

template<typename **ComponentTag**>

class **base_lco_with_value**<void, void, *ComponentTag*> : public *hpx*::*lcos*::*base_lco*, public *ComponentTag*

#include <base_lco_with_value.hpp> The base_lco<void> specialization is used whenever the set_event action for a particular LCO doesn't carry any argument.

Template Parameters

void – This specialization expects no result value and is almost completely equivalent to the plain base_lco.

Public Types

using **wrapping_type** = detail::base_lco_wrapping_type<*ComponentTag*, base_lco_with_value>::type

using **base_type_holder** = base_lco_with_value

hpx::sync (distributed)

Defined in header hpx/async.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::sync

template<typename **Action**, typename **F**, typename ...**Ts**>
auto *hpx*::**sync**(*F* &&f, *Ts*&&... ts) -> decltype(detail::sync_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *sync* runs the function *f* synchronously and returns a hpx::future that will eventually hold the result of that function call.

template<typename **Action**, typename **F**, typename ...**Ts**>
auto *hpx*::**sync**(*F* &&f, *Ts*&&... ts) -> decltype(detail::sync_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *sync* runs the function *f* synchronously and returns a hpx::future that will eventually hold the result of that function call.

Warning

doxygenfunction: Unable to resolve function "hpx::sync" with arguments (Action&&, Target&&, Ts&&…) in doxygen xml output for project "hpx" from directory: ../hpx_autodoc. Potential matches:

```

↪> decltype(detail::sync_action_dispatch<Action, std::decay_t<F>>::call(std::forward
↪<F>(f), std::forward<Ts>(ts)...))
- template<typename Action, typename Target, typename ...Ts> decltype(auto)␣
↪sync(Action &&action, Target &&target, Ts&&... ts)
- template<typename F, typename ...Ts> decltype(auto) sync(F &&f, Ts&&... ts)
```

hpx/async_distributed/promise.hpp

Defined in header hpx/async_distributed/promise.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **distributed**

Functions

template<typename **Result**, typename **RemoteResult**>
void **swap**(*promise*<*Result*, *RemoteResult*> &x, *promise*<*Result*, *RemoteResult*> &y) noexcept

template<typename **Result**, typename **RemoteResult**>

class **promise** : public *lcos*::detail::promise_base<*Result*, *RemoteResult*, *lcos*::detail::promise_data<*Result*>>

#include <promise.hpp> A promise can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the promise using the LCO's set_event action

A promise is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*. The *promise* allows to synchronize exactly one *thread* (the one passed during construction time).

```
// Create the promise (the expected result is a id_type)
hpx::distributed::promise<hpx::id_type> p;

// Get the associated future
future<hpx::id_type> f = p.get_future();

// initiate the action supplying the promise as a
// continuation
apply<some_action>(new continuation(p.get_id()), ...);

// Wait for the result to be returned, yielding control
// in the meantime.
hpx::id_type result = f.get();
// ...
```

Note

The action executed by the promise must return a value of a type convertible to the type as specified by the template parameter *RemoteResult*

Template Parameters

- **Result** – The template parameter *Result* defines the type this promise is expected to return from *promise::get*.
- **RemoteResult** – The template parameter *RemoteResult* defines the type this promise is expected to receive from the remote action.

Public Functions

promise() = default

constructs a promise object and a shared state.

template<typename **Allocator**>
inline **promise**(*std*::allocator_arg_t, *Allocator* const &a)

constructs a promise object and a shared state. The constructor uses the allocator *to* allocate the memory for the shared state.

promise(*promise* &&other) noexcept = default

constructs a new promise object and transfers ownership of the shared state of other (if any) to the newly- constructed object.

Post

other has no shared state.

~promise() = default

Abandons any shared state.

promise &**operator=**(*promise* &&other) noexcept = default

Abandons any shared state (30.6.4) and then as if promise(HPX_MOVE(other)).swap(*this).

Returns

*this.

inline void **swap**(*promise* &other) noexcept

Exchanges the shared state of *this and other.

Post

*this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

Private Types

using **base_type** = *lcos*::detail::promise_base<*Result*, *RemoteResult*, *lcos*::detail::promise_data<*Result*>>

template<>

class **promise**<void, *hpx*::*util*::unused_type> : public *lcos*::detail::promise_base<void, *hpx*::*util*::unused_type, *lcos*::detail::promise_data<void>>

Public Functions

promise() = default

constructs a promise object and a shared state.

template<typename **Allocator**>
inline **promise**(*std*::allocator_arg_t, *Allocator* const &a)

constructs a promise object and a shared state. The constructor uses the allocator *to* allocate the memory for the shared state.

promise(*promise* &&other) noexcept = default

constructs a new promise object and transfers ownership of the shared state of other (if any) to the newly- constructed object.

Post

other has no shared state.

~promise() = default

Abandons any shared state.

promise &**operator=**(*promise* &&other) noexcept = default

Abandons any shared state (30.6.4) and then as if promise(HPX_MOVE(other)).swap(*this).

Returns

*this.

inline void **swap**(*promise* &other) noexcept

Exchanges the shared state of *this and other.

Post

*this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

inline void **set_value**()

atomically stores the value r in the shared state and makes that state ready (30.6.4).

Throws

`future_error` – if its shared state already has a stored value. if shared state has no stored value exception is raised. promise_already_satisfied if its shared state already has a stored value or exception. no_state if *this has no shared state.

Private Types

using **base_type** = *lcos*::detail::promise_base<void, *hpx*::*util*::unused_type, *lcos*::detail::promise_data<void>>

template<>

struct **get_lva**<*hpx*::*lcos*::*base_lco* const>

Public Static Functions

static inline constexpr *hpx*::*lcos*::*base_lco* const ***call**(*hpx*::*naming*::address_type lva) noexcept

namespace **lcos**

class **base_lco**

#include <base_lco.hpp> The base_lco class is the common base class for all LCO's implementing a simple set_event action

Subclassed by *hpx::lcos::base_lco_with_value< Result, RemoteResult, ComponentTag >*, *hpx::lcos::base_lco_with_value< void, void, ComponentTag >*

Public Types

typedef *components*::*managed_component*<*base_lco*> **wrapping_type**

typedef *base_lco* **base_type_holder**

Public Functions

virtual void **set_event**() = 0

virtual void **set_exception**(*std*::exception_ptr const &e)

virtual void **connect**(*hpx*::*id_type* const&)

virtual void **disconnect**(*hpx*::*id_type* const&)

virtual **~base_lco**()

Destructor, needs to be virtual to allow for clean destruction of derived objects

void **set_event_nonvirt**()

The *function* set_event_nonvirt is called whenever a *set_event_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set_event*, which is overloaded by the derived concrete LCO.

void **set_exception_nonvirt**(*std*::exception_ptr const &e)

The *function* set_exception is called whenever a *set_exception_action* is applied on a instance of a LCO. This function just forwards to the virtual function *set_exception*, which is overloaded by the derived concrete LCO.

Parameters

e – [in] The exception encapsulating the error to report to this LCO instance.

void **connect_nonvirt**(*hpx*::*id_type* const &id)

The *function* connect_nonvirt is called whenever a *connect_action* is applied on a instance of a LCO. This function just forwards to the virtual function *connect*, which is overloaded by the derived concrete LCO.

Parameters

id – [in] target id

void **disconnect_nonvirt**(*hpx*::*id_type* const &id)

The *function* disconnect_nonvirt is called whenever a *disconnect_action* is applied on a instance of a LCO. This function just forwards to the virtual function *disconnect*, which is overloaded by the derived concrete LCO.

Parameters

id – [in] target id

Public Static Functions

static *components*::*component_type* **get_component_type**() noexcept

Returns the component type associated with this LCO.

static void **set_component_type**(*components*::*component_type* type)

Sets the component type associated with this LCO.

Parameters

type – The component type to associate with this LCO.

hpx::post (distributed)

Defined in header hpx/async.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::post

template<typename **F**, typename ...**Ts**>

bool *hpx*::**post**(*F* &&f, *Ts*&&... ts)

Runs the function `f` asynchronously (potentially in a separate thread which might be a part of a thread pool). This is done in a fire-and-forget manner, meaning there is no return value or way to synchronize with the function execution (it does not return an *`hpx::future`* that would hold the result of that function call).

`hpx::post` is particularly useful when synchronization mechanisms as heavyweight as futures are not desired, and instead, more lightweight mechanisms like latches or atomic variables are preferred. Essentially, the post function enables the launch of a new thread without the overhead of creating a future.

> **Note**
>
> *`hpx::post`* is similar to `hpx::async` but does not return a future. This is why there is no way of finding out the result/failure of the execution of this function.

template<typename **Action**, typename **Target**, typename ...**Ts**>
bool *hpx*::**post**(*Action* &&action, *Target* &&target, *Ts*&&... ts)

The distributed implementation of *`hpx::post`* can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID.

Template Parameters

- **`Action`** – The type of action instance
- **`Target`** – The type of target where the action should be executed
- **`Ts`** – The type of any additional arguments

Parameters

- **`action`** – The action instance to be executed
- **`target`** – The target where the action should be executed
- **`ts`** – Additional arguments

Returns

`true` if the action was successfully posted, `false` otherwise.

hpx/async_distributed/async_continue_callback_fwd.hpp

Defined in header hpx/async_distributed/async_continue_callback_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

hpx/async_distributed/trigger.hpp

Defined in header hpx/async_distributed/trigger.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **actions**

Functions

template<typename **Result**, typename **RemoteResult**, typename **F**, typename ...**Ts**>
void **trigger**(*typed_continuation*<*Result*, *RemoteResult*> &&cont, *F* &&f, *Ts*&&… vs) noexcept

Invoke *f* with the given arguments and forward its result to *cont*.

On success, the result of invoking *f* is passed to *cont.trigger_value()*. If invoking *f* throws, the exception is forwarded to the destination instead by calling *cont.trigger_error()* so that hpx::exceptions are propagated back to the client.

Parameters

- **cont** – The continuation that either the result or an exception is delivered to.
- **f** – The callable to invoke.
- **vs** – The arguments to invoke *f* with.

template<typename **Result**, typename **F**, typename ...**Ts**>
void **trigger**(*typed_continuation*<*Result*, *util*::unused_type> &&cont, *F* &&f, *Ts*&&… vs) noexcept

Invoke *f* with the given arguments and notify *cont* of completion. Overload for when the return type is “void” aka util::unused_type.

On success, *cont.trigger()* is called to signal completion. If invoking *f* throws, the exception is forwarded to the destination instead by calling *cont.trigger_error()* so that hpx::exceptions are propagated back to the client.

Parameters

- **cont** – The continuation that completion or an exception is delivered to.
- **f** – The callable to invoke.
- **vs** – The arguments to invoke *f* with.

hpx::distributed::promise

Defined in header hpx/future.hpp[1012].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Result**, typename **RemoteResult**>

class **promise** : public *lcos*::detail::promise_base<*Result*, *RemoteResult*, *lcos*::detail::promise_data<*Result*>>

A promise can be used by a single *thread* to invoke a (remote) action and wait for the result. The result is expected to be sent back to the promise using the LCO’s set_event action

A promise is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type *Result*. The *promise* allows to synchronize exactly one *thread* (the one passed during construction time).

```
// Create the promise (the expected result is a id_type)
hpx::distributed::promise<hpx::id_type> p;

// Get the associated future
future<hpx::id_type> f = p.get_future();

// initiate the action supplying the promise as a
// continuation
apply<some_action>(new continuation(p.get_id()), ...);

```

(continues on next page)

[1012] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/future.hpp

(continued from previous page)

```
// Wait for the result to be returned, yielding control
// in the meantime.
hpx::id_type result = f.get();
// ...
```

Note

The action executed by the promise must return a value of a type convertible to the type as specified by the template parameter *RemoteResult*

Template Parameters

- **`Result`** – The template parameter *Result* defines the type this promise is expected to return from *promise::get*.
- **`RemoteResult`** – The template parameter *RemoteResult* defines the type this promise is expected to receive from the remote action.

hpx/async_distributed/continuation.hpp

Defined in header hpx/async_distributed/continuation.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`actions`**

class **`continuation`**

Subclassed by *hpx::actions::typed_continuation< Result, Result >*, *hpx::actions::typed_continuation< void, util::unused_type >*

hpx/async_distributed/trigger_lco_fwd.hpp

Defined in header hpx/async_distributed/trigger_lco_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

Functions

void **`trigger_lco_event`**(*hpx*::*id_type* id, *naming*::*address* &&addr, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should be triggered.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **`trigger_lco_event`**(*hpx*::*id_type* const &id, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should be triggered.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`trigger_lco_event`**(*hpx*::*id_type* id, *naming*::*address* &&addr, *hpx*::*id_type* const &cont, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should be triggered.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **trigger_lco_event**(*hpx*::*id_type* const &id, *hpx*::*id_type* const &cont, bool move_credits = true)

Trigger the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should be triggered.
- **cont** – [in] This represents the LCO to trigger after completion.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
void **set_lco_value**(*hpx*::*id_type* id, *naming*::*address* &&addr, *Result* &&t, bool move_credits = true)

Set the result value for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
void **set_lco_value**(*hpx*::*id_type* const &id, *Result* &&t, bool move_credits = true)

Set the result value for the (managed) LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
void **set_lco_value_unmanaged**(*hpx*::*id_type* const &id, *Result* &&t, bool move_credits = true)

Set the result value for the (unmanaged) LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **t** – [in] This is the value which should be sent to the LCO.
- **move_credits** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **Result**>
void **set_lco_value**(*hpx*::*id_type* id, *naming*::*address* &&addr, *Result* &&t, *hpx*::*id_type* const &cont, bool move_credits = true)

Set the result value for the LCO referenced by the given id.

Parameters

- **id** – [in] This represents the id of the LCO which should receive the given value.
- **addr** – [in] This represents the addr of the LCO which should be triggered.
- **t** – [in] This is the value which should be sent to the LCO.

- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **`Result`**>
void **`set_lco_value`**(*hpx*::*id_type* const &id, *Result* &&t, *hpx*::*id_type* const &cont, bool move_credits = true)

Set the result value for the (managed) LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the given value.
- **`t`** – [in] This is the value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

template<typename **`Result`**>
void **`set_lco_value_unmanaged`**(*hpx*::*id_type* const &id, *Result* &&t, *hpx*::*id_type* const &cont, bool move_credits = true)

Set the result value for the (unmanaged) LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the given value.
- **`t`** – [in] This is the value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::*id_type* id, *naming*::*address* &&addr, *std*::exception_ptr const &e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::*id_type* id, *naming*::*address* &&addr, *std*::exception_ptr &&e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`e`** – [in] This is the error value which should be sent to the LCO.

- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **`set_lco_error`**(*hpx*::*id_type* const &id, *std*::exception_ptr const &e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **`set_lco_error`**(*hpx*::*id_type* const &id, *std*::exception_ptr &&e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::*id_type* id, *naming*::*address* &&addr, *std*::exception_ptr const &e, *hpx*::*id_type* const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

void **`set_lco_error`**(*hpx*::*id_type* id, *naming*::*address* &&addr, *std*::exception_ptr &&e, *hpx*::*id_type* const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`addr`** – [in] This represents the addr of the LCO which should be triggered.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **`set_lco_error`**(*hpx*::*id_type* const &id, *std*::exception_ptr const &e, *hpx*::*id_type* const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

inline void **`set_lco_error`**(*hpx*::*id_type* const &id, *std*::exception_ptr &&e, *hpx*::*id_type* const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- **`id`** – [in] This represents the id of the LCO which should receive the error value.
- **`e`** – [in] This is the error value which should be sent to the LCO.
- **`cont`** – [in] This represents the LCO to trigger after completion.
- **`move_credits`** – [in] If this is set to *true* then it is ok to send all credits in *id* along with the generated message. The default value is *true*.

hpx::async (distributed)

Defined in header hpx/async.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also

hpx::async

template<typename **`Action`**, typename **`F`**, typename ...**`Ts`**>
auto **`hpx::async`**(*F* &&f, *Ts*&&... ts) -> decltype(detail::async_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *async* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a hpx::future that will eventually hold the result of that function call. If no policy is defined, *async* behaves as if it is called with policy being *hpx::launch::async* | hpx::launch::deferred. Otherwise, it calls a function *f* with arguments *ts* according to a specific launch policy.

- If the async flag is set (i.e. (policy & hpx::launch::async) != 0), then async executes the callable object f on a new thread of execution (with all thread-locals initialized) as if spawned by *hpx::thread*(std::forward<F>(f), std::forward<Ts>(ts)…), except that if the function f returns a value or throws an exception, it is stored in the shared state accessible through the *hpx::future* that async returns to the caller.
- If the deferred flag is set (i.e. (policy & hpx::launch::deferred) != 0), then async converts f and ts… the same way as by *hpx::thread* constructor, but does not spawn a new thread of execution. Instead, lazy evaluation is performed: the first call to a non-timed wait function on the *hpx::future* that async returned to the caller will cause the copy of f to be invoked (as a rvalue) with the copies of ts… (also passed as rvalues) in the current thread (which does not have to be the thread that originally called hpx::async). The result or exception is placed in the shared state associated with the future and only then it is made ready. All further accesses to the same *hpx::future* will return the result immediately.
- If neither hpx::launch::async nor hpx::launch::deferred, nor any implementation-defined policy flag is set in policy, the behavior is undefined.

If more than one flag is set, it is implementation-defined which policy is selected. For the default (both the hpx::launch::async and hpx::launch::deferred flags are set in policy), standard recommends (but doesn't require) utilizing available concurrency, and deferring any additional tasks.

In any case, the call to hpx::async synchronizes-with (as defined in std::memory_order) the call to f, and the completion of f is sequenced-before making the shared state ready. If the async policy is chosen, the associated thread completion synchronizes-with the successful return from the first function that is waiting on the shared state, or with the return of the last function that releases the shared state, whichever comes first. If std::decay<Function>::type or each type in std::decay<Ts>::type is not constructible from its corresponding argument, the program is ill-formed.

Parameters

- `f` – Callable object to call
- `ts` – parameters to pass to f

Returns

hpx::future referring to the shared state created by this call to *hpx::async*.

template<typename **Action**, typename **F**, typename ...**Ts**>
auto **hpx::async**(*F* &&f, *Ts*&&... ts) -> decltype(detail::async_action_dispatch<*Action*, *std*::decay_t<*F*>>::call(*std*::forward<*F*>(*f*), *std*::forward<*Ts*>(*ts*)...))

The function template *async* runs the function *f* asynchronously (potentially in a separate thread which might be a part of a thread pool) and returns a hpx::future that will eventually hold the result of that function call. If no policy is defined, *async* behaves as if it is called with policy being *hpx::launch::async* | hpx::launch::deferred. Otherwise, it calls a function *f* with arguments *ts* according to a specific launch policy.

- If the async flag is set (i.e. (policy & hpx::launch::async) != 0), then async executes the callable object f on a new thread of execution (with all thread-locals initialized) as if spawned by *hpx::thread*(std::forward<F>(f), std::forward<Ts>(ts)…), except that if the function f returns a value or throws an exception, it is stored in the shared state accessible through the *hpx::future* that async returns to the caller.
- If the deferred flag is set (i.e. (policy & hpx::launch::deferred) != 0), then async converts f and ts… the same way as by *hpx::thread* constructor, but does not spawn a new thread of execution. Instead, lazy evaluation is performed: the first call to a non-timed wait function on the *hpx::future* that async returned to the caller will cause the copy of f to be invoked (as a rvalue) with the copies of ts… (also passed as rvalues) in the current thread (which does not have to be the thread that originally called hpx::async). The result or exception is placed in the shared state associated with the future and only then it is made ready. All further accesses to the same *hpx::future* will return the result immediately.
- If neither hpx::launch::async nor hpx::launch::deferred, nor any implementation-defined policy flag is set in policy, the behavior is undefined.

If more than one flag is set, it is implementation-defined which policy is selected. For the default (both the hpx::launch::async and hpx::launch::deferred flags are set in policy), standard recommends (but doesn't require) utilizing available concurrency, and deferring any additional tasks.

In any case, the call to hpx::async synchronizes-with (as defined in std::memory_order) the call to f, and the completion of f is sequenced-before making the shared state ready. If the async policy is chosen, the associated thread completion synchronizes-with the successful return from the first function that is waiting on the shared state, or with the return of the last function that releases the shared state, whichever comes first. If std::decay<Function>::type or each type in std::decay<Ts>::type is not constructible from its corresponding argument, the program is ill-formed.

Parameters

- `f` – Callable object to call
- `ts` – parameters to pass to f

Returns

hpx::future referring to the shared state created by this call to *hpx::async*.

Warning

doxygenfunction: Unable to resolve function "hpx::async" with arguments (Executor&&, hpx::sycl::experimental::sycl_executor::queue_function_ptr_t<Ts…>&&, Ts&&…) in doxygen xml output for project "hpx" from directory: ../hpx_autodoc. Potential matches:

```
- template<typename Action, typename F, typename ...Ts> auto async(F &&f, Ts&&... ts)␣
↪-> decltype(detail::async_action_dispatch<Action, std::decay_t<F>>
↪::call(std::forward<F>(f), std::forward<Ts>(ts)...))
- template<typename Action, typename Target, typename ...Ts> auto async(Action &&
↪action, Target &&target, Ts&&... ts)
- template<typename Executor, typename ...Ts> decltype(auto) async(Executor &&exec,␣
↪hpx::sycl::experimental::sycl_executor::queue_function_ptr_t<Ts...> &&f, Ts&&... ts)
- template<typename F, typename ...Ts> decltype(auto) async(F &&f, Ts&&... ts)
```

template<typename **Action**, typename **Target**, typename ...**Ts**>
auto *hpx*::**async**(*Action* &&action, *Target* &&target, *Ts*&&... ts)

The distributed implementation of `hpx::async` can be used by giving an action instance as argument instead of a function, and also by providing another argument with the locality ID or the target ID. The action executes asynchronously.

Template Parameters

- **Action** – The type of action instance
- **Target** – The type of target where the action should be executed
- **Ts** – The type of any additional arguments

Parameters

- **action** – The action instance to be executed
- **target** – The target where the action should be executed
- **ts** – Additional arguments

Returns

hpx::future referring to the shared state created by this call to `hpx::async`

hpx/async_distributed/packaged_action.hpp

hpx/checkpoint/checkpoint.hpp

Defined in header hpx/checkpoint/checkpoint.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

This header defines the save_checkpoint and restore_checkpoint functions. These functions are designed to help HPX application developer's checkpoint their applications. Save_checkpoint serializes one or more objects and saves them as a byte stream. Restore_checkpoint converts the byte stream back into instances of the objects.

namespace **hpx**

namespace **util**

Functions

std::ostream &**operator<<**(*std*::ostream &ost, *checkpoint* const &ckp)

Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters

- `ost` – Output stream to write to.
- `ckp` – Checkpoint to copy from.

Returns

Operator<< returns the ostream object.

std::istream &**operator>>**(*std*::istream &ist, *checkpoint* &ckp)

Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

Parameters

- `ist` – Input stream to write from.
- `ckp` – Checkpoint to write to.

Returns

Operator>> returns the ostream object.

template<typename **T**, typename ...**Ts**>
hpx::*future*<*checkpoint*> **save_checkpoint**(*T* &&t, *Ts*&&... ts)

Save_checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- `T` – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts` – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `U` – This parameter is used to make sure that T is not a launch policy or a checkpoint. This forces the compiler to choose the correct overload.

Parameters

- **`t`** – A container to restore.
- **`ts`** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **`T`**, typename ...**`Ts`**>
hpx::*future*<*checkpoint*> **`save_checkpoint`**(*checkpoint* &&c, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Take a pre-initialized checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **`T`** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **`Ts`** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- **`c`** – Takes a pre-initialized checkpoint to copy data into.
- **`t`** – A container to restore.
- **`ts`** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **`T`**, typename ...**`Ts`**>
hpx::*future*<*checkpoint*> **`save_checkpoint`**(*hpx*::*launch* p, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Policy overload

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **`T`** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **`Ts`** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- **`p`** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **`t`** – A container to restore.
- **`ts`** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>
hpx::*future*<*checkpoint*> **save_checkpoint**(*hpx*::*launch* p, *checkpoint* &&c, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Policy overload & pre-initialized checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- **p** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename **T**, typename ...**Ts**>
checkpoint **save_checkpoint**(*hpx*::*launch*::sync_policy sync_p, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Sync_policy overload

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **U** – This parameter is used to make sure that T is not a checkpoint. This forces the compiler to choose the correct overload.

Parameters

- **sync_p** – hpx::launch::sync_policy
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename **T**, typename ...**Ts**>
checkpoint **save_checkpoint**(*hpx*::*launch*::sync_policy sync_p, *checkpoint* &&c, *T* &&t, *Ts*&&... ts)

Save_checkpoint - Sync_policy overload & pre-init. checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters

- **T** – Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts** – More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters

- **sync_p** – hpx::launch::sync_policy
- **c** – Takes a pre-initialized checkpoint to copy data into.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename **T**, typename ...**Ts**>
hpx::*future*<*checkpoint*> **prepare_checkpoint**(*T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **T**, typename ...**Ts**>
hpx::*future*<*checkpoint*> **prepare_checkpoint**(*checkpoint* &&c, *T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- **`T`** – A container to restore.
- **`Ts`** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **`c`** – Takes a pre-initialized checkpoint to prepare
- **`t`** – A container to restore.
- **`ts`** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **`T`**, typename ...**`Ts`**>
hpx::*future*<*checkpoint*> **`prepare_checkpoint`**(*hpx*::*launch* p, *T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- **`T`** – A container to restore.
- **`Ts`** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **`p`** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **`t`** – A container to restore.
- **`ts`** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **`T`**, typename ...**`Ts`**>
hpx::*future*<*checkpoint*> **`prepare_checkpoint`**(*hpx*::*launch* p, *checkpoint* &&c, *T* const &t, *Ts* const&... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Template Parameters

- **`T`** – A container to restore.
- **`Ts`** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **`p`** – Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **`c`** – Takes a pre-initialized checkpoint to prepare
- **`t`** – A container to restore.
- **`ts`** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

template<typename **T**, typename ...**Ts**>
void **restore_checkpoint**(*checkpoint* const &c, *T* &t, *Ts*&... ts)

Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save_checkpoint). Restore_checkpoint can resurrect a stored component in two ways: by passing in an instance of a component's shared_ptr or by passing in an instance of the component's client.

Template Parameters

- **T** – A container to restore.
- **Ts** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **c** – The checkpoint to restore.
- **t** – A container to restore.
- **ts** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Restore_checkpoint returns void.

class **checkpoint**

#include <checkpoint.hpp> Checkpoint Object

Checkpoint is the container object which is produced by save_checkpoint and is consumed by a restore_checkpoint. A checkpoint may be moved into the save_checkpoint object to write the byte stream to the pre-created checkpoint object.

Checkpoints are able to store all containers which are serializable including components.

Friends

friend class hpx::serialization::access

friend *std*::ostream &**operator<<**(*std*::ostream &ost, *checkpoint* const &ckp)

Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint's data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters

- **ost** – Output stream to write to.
- **ckp** – Checkpoint to copy from.

Returns

Operator<< returns the ostream object.

friend *std*::istream &**operator>>**(*std*::istream &ist, *checkpoint* &ckp)

Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint's data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

Parameters

- **ist** – Input stream to write from.
- **ckp** – Checkpoint to write to.

Returns

Operator>> returns the ostream object.

template<typename **T**, typename ...**Ts**>

friend void **`restore_checkpoint`**`(`*checkpoint* const &c, *T* &t, *Ts*&... ts`)`

Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save_checkpoint). Restore_checkpoint can resurrect a stored component in two ways: by passing in an instance of a component's shared_ptr or by passing in an instance of the component's client.

Template Parameters

- **`T`** – A container to restore.
- **`Ts`** – Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters

- **`c`** – The checkpoint to restore.
- **`t`** – A container to restore.
- **`ts`** – Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Returns

Restore_checkpoint returns void.

inline friend bool **`operator==`**`(`*checkpoint* const &lhs, *checkpoint* const &rhs`)` noexcept

- *hpx::collectives::hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

struct **`communicator`**

A communicator instance represents the list of sites that participate in a particular collective operation.

hpx::collectives::create_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_local_communicator*
- *hpx::collectives::create_hierarchical_communicator*
- *hpx::collectives::hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

communicator `hpx::collectives::`**`create_communicator`**(char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Create a new communicator object usable with any collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of the collective operations (such as *all_gather*, *all_reduce*, *all_to_all*, *broadcast*, etc.).

Parameters

- **`basename`** – The base name identifying the collective operation
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **`root_site`** – The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

Throws

`hpx::exception` – with hpx::error::bad_parameter if *basename* is null or empty, if the (resolved) *num_sites* is zero, if the (resolved) *this_site* is not smaller than *num_sites*, or if the (resolved) *root_site* does not designate a participating site.

Returns

This function returns a new communicator object usable with the collective operation.

hpx::collectives::create_local_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*
- *hpx::collectives::create_communicator*
- *hpx::collectives::create_hierarchical_communicator*

- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

communicator `hpx::collectives::`**`create_local_communicator`**(char const *basename, *num_sites_arg* num_sites, *this_site_arg* this_site, *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Create a new communicator object usable with any local collective operation

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of the collective operations (such as *all_gather*, *all_reduce*, *all_to_all*, *broadcast*, etc.).

Parameters

- **`basename`** – The base name identifying the collective operation
- **`num_sites`** – The number of participating sites
- **`this_site`** – The sequence number of this invocation (usually the sequence number of the object participating in the collective operation). This value must be in the range [0, num_sites).
- **`generation`** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **`root_site`** – The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

Throws

`hpx::exception` – with hpx::error::bad_parameter if *basename* is null or empty, if *num_sites* is unspecified or zero, if *this_site* is unspecified or not smaller than *num_sites*, or if the (resolved) *root_site* does not designate a participating site.

Returns

This function returns a new communicator object usable for all local collective operations.

hpx::collectives::create_hierarchical_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::communicator*

- *hpx::collectives::create_local_communicator*
- *hpx::collectives::hierarchical_communicator*
- *hpx::collectives::communicator::set_info*
- *hpx::collectives::communicator::get_info*
- *hpx::collectives::communicator::is_root*

hierarchical_communicator `hpx::collectives::`**`create_hierarchical_communicator`**(char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *arity_arg* arity = *arity_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*(), *flat_fallback_threshold_arg* threshold = *flat_fallback_threshold_arg*())

Create a new hierarchical communicator object usable with collective operations

This functions creates a new *hierarchical_communicator* object that can be called in order to pre-allocate a communicator object usable with multiple invocations of a collective operation (such as *all_gather*, *all_reduce*, *all_to_all*, *broadcast*, etc.).

Note

The sub-communicators of a *hierarchical_communicator* share one generation sequence per registered name. Every hierarchical collective advances each sub-communicator it touches by exactly two internal generations per call (a single-pass collective such as *broadcast*, *gather*, *scatter* or *reduce*, and the inter-group exchange of *all_to_all*, skip the second generation in one step rather than performing a second round-trip). A single *hierarchical_communicator* instance may therefore be shared freely across collective operations, provided every call uses an explicit, strictly consecutive generation number so the shared sequence stays gap-free. Because the two-phase hierarchical collectives (*all_gather*, *all_reduce*, *all_to_all*, *inclusive_scan*, *exclusive_scan* and the hierarchical *barrier*) derive their phase generations from that explicit number, they require it and reject an auto (default) generation. The non-hierarchical (flat) collectives keep supporting the default generation, falling back to the internal per-communicator counter maintained in the and_gate. Once any operation on a communicator has used that default, later operations on the same instance may no longer pass an explicit generation number: the counter's position is no longer reliably known to the caller. The reverse transition, from explicit numbering back to the default, remains valid. All participants of a single operation must use the same generation mode.

Note

Hierarchical collective overloads that return *hpx::future* may still perform internal waits while walking the communicator tree. They should not be treated as fully non-blocking: validation failures are reported through the returned exceptional future, but internal phase hand-offs can throw or block before that future is delivered.

Parameters

- **`basename`** – The base name identifying the collective operation
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`arity`** – The arity of the hierarchical tree of communicators to create for the given endpoint. The default arity is 2 and the value must be at least 2.
- **`generation`** – The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **`root_site`** – The site at the root of the tree of communicators (default: 0). Any site may serve as the root. All sites must pass the same root site. The root site is the only site that may call the root-side operations (broadcast_to, gather_here, reduce_here, scatter_to). In the composite operations that take a *root_site* argument (all_gather, all_reduce, barrier, scans) it must be 0 (the default) or the root of the communicator; an explicit 0 is not checked.
- **`threshold`** – The site-count threshold below which the communicator collapses to a single flat communicator spanning all sites (strict comparison: num_sites < threshold). The default is 16; pass 0 to disable the fallback. The communicator is still a single flat communicator if *arity* is not smaller than the number of sites.

Throws

`hpx::exception` – with hpx::error::bad_parameter if *basename* is null or empty, if the (resolved) *num_sites* is zero, if the (resolved) *this_site* is not smaller than *num_sites*, if the (resolved) *root_site* is not smaller than *num_sites*, or if *arity* is smaller than 2.

Returns

This function returns a new communicator object usable with the collective operation.

hpx::collectives::hierarchical_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::collectives::scatter_from

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::scatter_to*

template<typename **T**>
hpx::*future*<*T*> `hpx::collectives::`**`scatter_from`**(char const *basename, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Parameters

- **`basename`** – The base name identifying the scatter operation
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`root_site`** – The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

template<typename **T**>

hpx::*future*<*T*> hpx::collectives::**scatter_from**(*communicator* comm, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

> **Note**
>
> The generation values from corresponding *scatter_to* and *scatter_from* have to match.

> **Note**
>
> The generation values from corresponding *scatter_to* and *scatter_from* have to match.

Parameters

- **`comm`** – A communicator object returned from *create_communicator*
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`comm`** – A communicator object returned from *create_communicator*
- **`generation`** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

Returns

This function returns a future holding the scattered value. It will become ready once the scatter operation has been completed.

template<typename **T**>
T hpx::collectives::**scatter_from**(*hpx*::*launch*::sync_policy, char const *basename, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Parameters

- **`basename`** – The base name identifying the scatter operation
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`root_site`** – The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

Returns

This function returns the scattered value. It executes synchronously and directly returns the result.

template<typename `T`>
T `hpx::collectives::`**`scatter_from`**(*hpx*::*launch*::sync_policy, *communicator* comm, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Note

The generation values from corresponding *scatter_to* and *scatter_from* have to match.

Note

The generation values from corresponding *scatter_to* and *scatter_from* have to match.

Parameters

- **`comm`** – A communicator object returned from *create_communicator*
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once. hpx::collectives::inclusive_scan

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **F**>
hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::`**`inclusive_scan`**(char const *basename, *T* &&result, *F* &&op, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Parameters

- **`basename`** – The base name identifying the inclusive_scan operation
- **`result`** – The value to transmit to all participating sites from this call site.
- **`op`** – Reduction operation to apply to all values supplied from all participating sites
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

- **generation** – The generational counter identifying the sequence number of the inclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **root_site** – The site that is responsible for creating the inclusive_scan support object. This value is optional and defaults to '0' (zero).

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

template<typename **T**, typename **F**>
hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::`**`inclusive_scan`**(*communicator* comm, *T* &&result, *F* &&op, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Inclusive inclusive_scan a set of values from different call sites

This function performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the inclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

hpx::distributed::latch

Defined in header hpx/latch.hpp[1013].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **latch** : public *hpx*::*components*::*client_base*<*latch*, *hpx*::*lcos*::server::latch>

Latch is an implementation of a synchronization primitive that allows multiple threads to wait for a shared event to occur before proceeding. This latch can be invoked in a distributed application.

For a local only latch

> **See also**
>
> *hpx::latch*.

hpx::collectives::all_to_all

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
hpx::*future*<*std*::vector<*T*>> `hpx::collectives::`**`all_to_all`**(char const *basename, *std*::vector<*T*> &&local_result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*(), pairwise_threshold_arg threshold = pairwise_threshold_arg())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **`basename`** – The base name identifying the all_to_all operation
- **`local_result`** – A vector of values to transmit to all participating sites from this call site.
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`root_site`** – The site that is responsible for creating the all_to_all support object. This value is optional and defaults to ‘0’ (zero).
- **`threshold`** – The fixed row-size threshold, in bytes, at or above which rows are exchanged directly between sites instead of being routed through one communicator site. Automatic selection uses sizeof(T) only for a trivially copyable T; other row types stay routed unless

---

[1013] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/latch.hpp every site passes zero. See *pairwise_threshold_arg* for the default and the remaining direct-exchange requirements. Successive generations using one basename may select different paths. Which path runs affects performance only, never the result.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

template<typename **T**>
hpx::*future*<*std*::vector<*T*>> `hpx::collectives::`**`all_to_all`**(*communicator* fid, *std*::vector<*T*> &&local_result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **`fid`** – A communicator object returned from *create_communicator*
- **`local_result`** – A vector of values to transmit to all participating sites from this call site.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`fid`** – A communicator object returned from *create_communicator*
- **`local_result`** – A vector of values to transmit to all participating sites from this call site.
- **`generation`** – The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

template<typename **T**>

std::vector<*T*> hpx::collectives::**all_to_all**(*hpx*::*launch*::sync_policy policy, char const *basename, *std*::vector<*T*> &&local_result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*(), pairwise_threshold_arg threshold = pairwise_threshold_arg())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **policy** – The execution policy specifying synchronous execution.
- **basename** – The base name identifying the all_to_all operation
- **local_result** – A vector of values to transmit to all participating sites from this call site.
- **num_sites** – The number of participating sites (default: all localities).
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

class **`channel_communicator`**

A handle identifying the communication channel to use for get/set operations

hpx::collectives::create_channel_communicator

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::channel_communicator*
- *hpx::collectives::get*
- *hpx::collectives::set*

hpx::*future*<*channel_communicator*> `hpx::collectives::`**`create_channel_communicator`**(char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*())

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

> **Note**
>
> The caller must ensure that the communicator object returned by this function is kept alive (i.e., does not go out of scope) until all participating sites have successfully connected. Destroying the communicator before all sites have reached the creation point may cause the remaining sites to hang indefinitely. Consider using a barrier or similar synchronization mechanism after creating the communicator to ensure all sites are connected before allowing it to be destroyed.

Parameters

- **`basename`** – The base name identifying the collective operation
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future to a new communicator object usable with the collective operation. The future becomes ready after the local endpoint has been registered. It does not wait for all participating sites to create their communicators.

channel_communicator `hpx::collectives::`**`create_channel_communicator`**(*hpx*::*launch*::sync_policy, char const *basename, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*())

Create a new communicator object usable with peer-to-peer channel-based operations

This functions creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

> **Note**
>
> The caller must ensure that the communicator object returned by this function is kept alive (i.e., does not go out of scope) until all participating sites have successfully connected. Destroying the communicator before all sites have reached the creation point may cause the remaining sites to hang indefinitely. Consider using a barrier or similar synchronization mechanism after creating the communicator to ensure all sites are connected before allowing it to be destroyed.

Parameters

- **`basename`** – The base name identifying the collective operation
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a new communicator object usable with the collective operation. It returns after the local endpoint has been registered and does not wait for all participating sites to create their communicators. It is not a global barrier.

hpx::collectives::get

Defined in header hpx/collectives.hpp.

template<typename **T**>

hpx::*future*<*T*> `hpx::collectives::get`(*channel_communicator* comm, *that_site_arg* site, *tag_arg* tag = *tag_arg*())

Send a value to the given site

This function receives a value from the given site based on the given communicator.

Parameters

- `comm` – The channel communicator object to use for the data transfer
- `site` – The source site
- `tag` – The (optional) tag identifying the concrete operation

Returns

This function returns a future<T> that becomes ready once the data transfer operation has finished. The future will hold the received value.

hpx::collectives::set

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::get*

template<typename **T**>
hpx::*future*<void> `hpx::collectives::set`(*channel_communicator* comm, *that_site_arg* site, *T* &&value, *tag_arg* tag = *tag_arg*())

Send a value to the given site

This function sends a value to the given site based on the given communicator.

Parameters

- `comm` – The channel communicator object to use for the data transfer
- `site` – The destination site
- `value` – The value to send
- `tag` – The (optional) tag identifying the concrete operation

Returns

This function returns a future<void> that becomes ready once the data transfer operation has finished.

hpx::collectives::broadcast_to

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::broadcast_from*

template<typename **T**>
hpx::*future*<*T*> `hpx::collectives::`**`broadcast_to`**(char const *basename, *T* &&local_result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

Parameters

- **`basename`** – The base name identifying the broadcast operation
- **`local_result`** – A value to transmit to all participating sites from this call site.
- **`num_sites`** – The number of participating sites (default: all localities).
- **`generation`** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

template<typename **T**>
hpx::*future*<*T*> `hpx::collectives::`**`broadcast_to`**(*communicator* comm, *T* &&local_result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Broadcast a value to different call sites

This function sends a set of values to all call sites operating on the given base name.

Note

The generation values from corresponding *broadcast_to* and *broadcast_from* have to match.

Parameters

- **`comm`** – A communicator object returned from *create_communicator*
- **`local_result`** – A value to transmit to all participating sites from this call site.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

- **generation** – The generational counter identifying the sequence number of the broadcast operation performed on the given base name. This is optional and needs to be supplied only if the broadcast operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.

Returns

This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

Returns

This function returns a vector with all values send by all participating sites. This function executes synchronously and directly returns the result.

hpx::distributed::barrier

Defined in header hpx/barrier.hpp[1014].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

explicit `hpx::distributed::barrier`(*std*::string const &base_name)

Creates a barrier, rank is locality id, size is number of localities

A barrier *base_name* is created. It expects that *hpx::get_num_localities()* participate and the local rank is *hpx::get_locality_id()*.

Parameters

`base_name` – The name of the barrier

`hpx::distributed::barrier`(*std*::string const &base_name, *std*::size_t num)

Creates a barrier with a given size, rank is locality id

A barrier *base_name* is created. It expects that *num* participate and the local rank is *hpx::get_locality_id()*.

Parameters

- **`base_name`** – The name of the barrier
- **`num`** – The number of participating threads

`hpx::distributed::barrier`(*std*::string const &base_name, *std*::size_t num, *std*::size_t rank)

Creates a barrier with a given size and rank

A barrier *base_name* is created. It expects that *num* participate and the local rank is *rank*.

Parameters

- **`base_name`** – The name of the barrier
- **`num`** – The number of participating threads
- **`rank`** – The rank of the calling site for this invocation

`hpx::distributed::barrier`(*std*::string const &base_name, *std*::vector<*std*::size_t> const &ranks, *std*::size_t rank)

Creates a barrier with a vector of ranks

A barrier *base_name* is created. It expects that ranks.size() and the local rank is *rank* (must be contained in *ranks*).

Parameters

- **`base_name`** – The name of the barrier
- **`ranks`** – Gives a list of participating ranks (this could be derived from a list of locality ids
- **`rank`** – The rank of the calling site for this invocation

---

hpx::collectives::all_gather

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**>
hpx::*future*<*std*::vector<*std*::decay_t<*T*>>> `hpx::collectives::`**`all_gather`**(char const *basename, *T* &&result, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **`basename`** – The base name identifying the all_gather operation
- **`result`** – The value to transmit to all participating sites from this call site.
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the all_gather operation performed on the given base name. This is optional and needs to be supplied only if the all_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`root_site`** – The site that is responsible for creating the all_gather support object. This value is optional and defaults to '0' (zero).

Returns

This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_gather operation has been completed.

template<typename **T**>
hpx::*future*<*std*::vector<*std*::decay_t<*T*>>> `hpx::collectives::`**`all_gather`**(*communicator* comm, *T* &&result, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to all participating sites from this call site.

- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the all_gather operation performed on the given base name. This is optional and needs to be supplied only if the all_gather operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`comm`** – A communicator object returned from *create_communicator*

- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::`**`this_site_arg`** = detail::argument_type<detail::this_site_tag>

The local end of the communication channel.

hpx::collectives::that_site_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::generation_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::`**`that_site_arg`** = detail::argument_type<detail::that_site_tag>

The opposite end of the communication channel.

hpx::collectives::generation_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*
- *hpx::collectives::that_site_arg*
- *hpx::collectives::root_site_arg*
- *hpx::collectives::tag_arg*
- *hpx::collectives::arity_arg*
- *hpx::collectives::flat_fallback_threshold_arg*

using `hpx::collectives::`**`generation_arg`** = detail::argument_type<detail::generation_tag>

The generational counter identifying the sequence number of the operation performed on the given base name. It needs to be supplied only if the operation on the given base name has to be performed more than once. It must be a positive number greater than zero. On any given communicator instance, operations that pass an explicit generation may not follow operations that used the default: the internal counter's position is no longer reliably known to the caller. The reverse transition, from explicit numbering back to the default, remains valid.

hpx::collectives::root_site_arg

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::collectives::num_sites_arg*
- *hpx::collectives::this_site_arg*

- *hpx::collectives::arity_arg*

using `hpx::collectives::`**`flat_fallback_threshold_arg`** = detail::argument_type<detail::flat_fallback_threshold_tag, 16>

> The site-count threshold below which a *hierarchical_communicator* collapses to a single flat communicator spanning all sites. At small site counts, flat collectives outperform hierarchical composition because tree-walking overhead exceeds the synchronization-depth benefit. Pass 0 to disable the fallback. The communicator is still a single flat communicator if the arity is not smaller than the number of sites.

hpx::collectives::exclusive_scan

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **F**>
hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::`**`exclusive_scan`**(char const *basename, *T* &&result, *F* &&op, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

> Exclusive scan a set of values from different call sites
>
> This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

> **Note**
>
> This no-init overload has MPI_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

Parameters

- **`basename`** – The base name identifying the exclusive_scan operation
- **`result`** – The value to transmit to all participating sites from this call site.
- **`op`** – Reduction operation to apply to all values supplied from all participating sites
- **`num_sites`** – The number of participating sites (default: all localities).
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`root_site`** – The site that is responsible for creating the exclusive_scan support object. This value is optional and defaults to '0' (zero).

Returns

For the participating site i this function returns the reduction (calculated according to the function op) of the values passed in by the participating sites 0, …, i-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the exclusive_scan operation has been completed.

template<typename **T**, typename **F**>
hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::`**`exclusive_scan`**(*communicator* comm, *T* &&result, *F* &&op, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

Exclusive scan a set of values from different call sites

This function performs an exclusive scan operation on a set of values received from all call sites operating on the given base name.

> **Note**
>
> This no-init overload has MPI_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

Note

This no-init overload has MPI_Exscan-like semantics, with a deterministic HPX first result: participating site 0 returns a value-initialized result (`std::decay_t<T>{}`, or `false` for `bool`). Use the overload taking an explicit `init` argument for C++ exclusive-scan semantics where site 0 returns `init`.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **generation** – The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **generation** – The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive_scan operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

For the participating site i this function returns the reduction (calculated according to the function op) of the values passed in by the participating sites 0, …, i-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the exclusive_scan operation has been completed.

Returns

For the participating site i this function returns a future the reduction (calculated according to the function op) of the values passed in by the participating sites 0, …, i-1. Participating site 0 returns a value-initialized result. The returned future will become ready once the exclusive_scan operation has been completed.

hpx::lcos::spmd_block

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::lcos::define_spmd_block*

struct **spmd_block**

The class *spmd_block* defines an interface for launching multiple images while giving handles to each image to interact with the remaining images. The *define_spmd_block* function templates create multiple images of a user-defined action and launches them in a possibly separate thread. A temporary spmd block object is created and diffused to each image. The constraint for the action given to the define_spmd_block function is to accept a *spmd_block* as first parameter.

hpx::collectives::all_reduce

Defined in header hpx/collectives.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **T**, typename **F**>
hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::all_reduce`(char const *basename, *T* &&result, *F* &&op, *num_sites_arg* num_sites = *num_sites_arg*(), *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*(), *root_site_arg* root_site = *root_site_arg*())

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **basename** – The base name identifying the all_reduce operation
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites
- **num_sites** – The number of participating sites (default: all localities).
- **generation** – The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **this_site** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **root_site** – The site that is responsible for creating the all_reduce support object. This value is optional and defaults to '0' (zero).

Returns

This function returns a future holding the result of combining the values sent by all participating sites using *op*. It will become ready once the all_reduce operation has been completed.

template<typename **T**, typename **F**>
hpx::*future*<*std*::decay_t<*T*>> `hpx::collectives::all_reduce`(*communicator* comm, *T* &&result, *F* &&op, *this_site_arg* this_site = *this_site_arg*(), *generation_arg* generation = *generation_arg*())

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Parameters

- **comm** – A communicator object returned from *create_communicator*
- **result** – The value to transmit to all participating sites from this call site.
- **op** – Reduction operation to apply to all values supplied from all participating sites

- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.
- **`generation`** – The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`comm`** – A communicator object returned from *create_communicator*
- **`result`** – The value to transmit to all participating sites from this call site.
- **`op`** – Reduction operation to apply to all values supplied from all participating sites
- **`generation`** – The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once. The generation number (if given) must be a positive number greater than zero.
- **`this_site`** – The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever *hpx::get_locality_id()* returns.

Returns

This function returns a future holding the result of combining the values sent by all participating sites using *op*. It will become ready once the all_reduce operation has been completed.

Returns

This function returns a future holding the result of combining the values sent by all participating sites using *op*. It will become ready once the all_reduce operation has been completed.

components

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::components::client_base

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **Derived**, typename **Stub**, typename **Data**>

class **client_base** : public *hpx*::*components*::stub_base<ServerComponent>

This class template serves as a base class for client components, providing common functionality such as managing shared state, ID retrieval, and asynchronous operations.

Template Parameters

- **Derived** – The derived client component type.
- **Stub** – The stub type used for communication.
- **Data** – The extra data type used for additional information.

hpx/components/get_ptr.hpp

Defined in header hpx/components/get_ptr.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

template<typename **Component**>
hpx::*future*<*std*::shared_ptr<*Component*>> **get_ptr**(*hpx*::*id_type* const &id)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

> **Note**
>
> This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise, the function will raise an error.

> **Note**
>
> The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

id – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

Template Parameters

Component – The type of the server side component.

Returns

This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

template<typename **Derived**, typename **Stub**, typename **Data**>
hpx::*future*<*std*::shared_ptr<typename *components*::*client_base*<*Derived*, *Stub*, *Data*>::server_component_type>> **get_ptr**(*con*
Stu
Da
con
&c

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

> **Note**
>
> This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise, the function will raise an error.

> **Note**
>
> The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

`c` – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.

Returns

This function returns a future representing the pointer to the underlying memory for the component instance with the given *id*.

template<typename **`Component`**>
std::shared_ptr<*Component*> **`get_ptr`**(*launch*::sync_policy p, *hpx*::*id_type* const &id, *error_code* &ec = *throws*)

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

> **Note**
>
> This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise, the function will raise and error.

> **Note**
>
> The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **`p`** – [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- **`id`** – [in] The global id of the component for which the pointer to the underlying memory should be retrieved.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Template Parameters

`Component` – The only template parameter has to be the type of the server side component.

Returns

This function returns the pointer to the underlying memory for the component instance with the given *id*.

template<typename **`Derived`**, typename **`Stub`**, typename **`Data`**>

std::shared_ptr<typename *components*::*client_base*<*Derived*, *Stub*, *Data*>::server_component_type> **get_ptr**(*launch*::sync_pol p, *components*::*client_bas* *Stub*, *Data*> const &c, *error_code* &ec = *throws*)

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

Note

This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise, the function will raise and error.

Note

The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Parameters

- **p** – [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- **c** – [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.
- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function returns the pointer to the underlying memory for the component instance with the given *id*.

hpx::components::client

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

template<typename **`Component`**, typename **`Data`** = void>

class **`client`** : public *hpx*::*components*::*client_base*<*client*<*Component*, void>, *Component*, void>

The client class is a wrapper that manages a distributed component. It extends `client_base` with specific `Component` and `Data` types.

Template Parameters

- **`Component`** – The type of the component.
- **`Data`** – The type of the data associated with the client (default is void).

hpx/components/basename_registration_fwd.hpp

Defined in header hpx/components/basename_registration_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

Functions

hpx::*future*<bool> **`register_with_basename`**(*std*::string base_name, *hpx*::*id_type* const &id, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Register the given id using the given base name.

The function registers the given ids using the provided base name.

Note

The operation will fail if the given sequence number is not unique.

Parameters

- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`id`** – [in] The id to register using the given base name.
- **`sequence_nr`** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

Returns

A future representing the result of the registration operation itself.

bool **`register_with_basename`**(*hpx*::*launch*::sync_policy, *std*::string base_name, *hpx*::*id_type* const &id, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0), *error_code* &ec = *throws*) *hpx*::*future*<bool> **`register_with_basename`**(*std*::string base_name, *hpx*::*future*<*hpx*::*id_type*> f, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Register the id wrapped in the given future using the given base name.

The function registers the object the given future refers to using the provided base name.

> **Note**
>
> The operation will fail if the given sequence number is not unique.

Parameters

- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`f`** – [in] The future which should be registered using the given base name.
- **`sequence_nr`** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

Returns

A future representing the result of the registration operation itself.

hpx/components/basename_registration.hpp

Defined in header hpx/components/basename_registration.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

Functions

std::vector<*hpx*::*future*<*hpx*::*id_type*>> **`find_all_from_basename`**(*std*::string base_name, *std*::size_t num_ids)

Return all registered ids from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return all registered clients from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

> **Note**
>
> The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Note

The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters

- `base_name` – [in] The base name for which to retrieve the registered ids.
- `num_ids` – [in] The number of registered ids to expect.
- `base_name` – [in] The base name for which to retrieve the registered ids.
- `num_ids` – [in] The number of registered ids to expect.

Returns

A list of futures representing the ids which were registered using the given base name.

Template Parameters

`Client` – The client type to return

Returns

A list of futures representing the ids which were registered using the given base name.

std::vector<*hpx*::*future*<*hpx*::*id_type*>> **`find_all_from_basename`**(*hpx*::*launch*::sync_policy, *std*::string base_name, *std*::size_t num_ids)

std::vector<*hpx*::*future*<*hpx*::*id_type*>> **`find_from_basename`**(*std*::string base_name, *std*::vector<*std*::size_t> const &ids)

Return registered ids from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Return registered clients from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Note

The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Note

The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters

- **base_name** – [in] The base name for which to retrieve the registered ids.
- **ids** – [in] The sequence numbers of the registered ids.
- **base_name** – [in] The base name for which to retrieve the registered ids.
- **ids** – [in] The sequence numbers of the registered ids.

Returns

A list of futures representing the ids which were registered using the given base name and sequence numbers.

Template Parameters

`Client` – The client type to return

Returns

A list of futures representing the ids which were registered using the given base name and sequence numbers.

std::vector<*hpx*::*future*<*hpx*::*id_type*>> **find_from_basename**(*hpx*::*launch*::sync_policy, *std*::string base_name, *std*::vector<*std*::size_t> const &ids)

hpx::*future*<*hpx*::*id_type*> **find_from_basename**(*std*::string base_name, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Return registered id from the given base name and sequence number.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

Note

The future will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Note

The future embedded in the returned client object will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters

- **base_name** – [in] The base name for which to retrieve the registered ids.
- **sequence_nr** – [in] The sequence number of the registered id.
- **base_name** – [in] The base name for which to retrieve the registered ids.
- **sequence_nr** – [in] The sequence number of the registered id.

Returns
A representing the id which was registered using the given base name and sequence numbers.

Template Parameters
`Client` – The client type to return

Returns
A representing the id which was registered using the given base name and sequence numbers.

hpx::*id_type* **`find_from_basename`**(*hpx*::*launch*::sync_policy, *std*::string base_name, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

hpx::*future*<*hpx*::*id_type*> **`unregister_with_basename`**(*std*::string base_name, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Unregister the given id using the given base name.

The function unregisters the given ids using the provided base name.

Unregister the given base name.

The function unregisters the given ids using the provided base name.

Parameters

- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`sequence_nr`** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register_with_basename* before.
- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`sequence_nr`** – [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with *register_with_basename* before.

Returns
A future representing the result of the un-registration operation itself.

Template Parameters
`Client` – The client type to return

Returns
A future representing the result of the un-registration operation itself.

template<typename **`Client`**, typename **`Stub`**, typename **`Data`**>
hpx::*future*<bool> **`register_with_basename`**(*std*::string base_name, *components*::*client_base*<*Client*, *Stub*, *Data*> &client, *std*::size_t sequence_nr = ~static_cast<*std*::size_t>(0))

Register the id wrapped in the given client using the given base name.

The function registers the object the given client refers to using the provided base name.

Note

The operation will fail if the given sequence number is not unique.

Template Parameters
`Client` – The client type to register

Parameters

- **`base_name`** – [in] The base name for which to retrieve the registered ids.
- **`client`** – [in] The client which should be registered using the given base name.
- **`sequence_nr`** – [in, optional] The sequential number to use for the registration of the id. This number has to be unique system-wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

Returns

A future representing the result of the registration operation itself.

HPX_REGISTER_STARTUP_MODULE

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

HPX_REGISTER_STARTUP_MODULE(startup)

Macro to register a startup module with the HPX runtime.

This macro facilitates the registration of a startup module with the HPX runtime system. A startup module typically contains initialization code that should be executed when the HPX runtime starts.

Parameters

- **startup** – The name of the startup function to be registered.

hpx/components_base/agas_interface.hpp

Defined in header hpx/components_base/agas_interface.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

HPX_REGISTER_COMMANDLINE_MODULE

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

`HPX_REGISTER_COMMANDLINE_MODULE`(add_options_function)

Macro to register a command-line module with the HPX runtime.

This macro facilitates the registration of a command-line module with the HPX runtime system. A command-line module typically provides additional command-line options that can be used to configure the HPX application.

Parameters

- **`add_options_function`** – The function that adds custom command-line options.

hpx::components::component

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::components::component_base*

template<typename **`Component`**>

class **`component`** : public *Component*

The *component* class wraps around a given component type, adding additional type aliases and constructors. It inherits from the specified component type.

hpx::components::component_base

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::components::component*

template<typename **`Component`**>

class **`component_base`** : public *hpx*::*components*::detail::base_component

component_base serves as a base class for components. It provides common functionality needed by components, such as address and ID retrieval. The template parameter *Component* specifies the derived component type.

hpx/components_base/get_lva.hpp

Defined in header hpx/components_base/get_lva.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

template<typename **Component**, typename **Enable** = void>

struct **get_lva**

#include <get_lva.hpp> The get_lva template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function *agas::addressing_service::resolve*) to the address of the component implementing the action.

The default implementation uses the template argument *Component* to deduce the type wrapping the component implementing the action. This is used to get the needed address.

Template Parameters

Component – This is the type of the component implementing the action to execute.

Public Static Functions

static inline constexpr *Component* ***call**(*naming*::address_type lva) noexcept

hpx/components_base/server/managed_component_base.hpp

Defined in header hpx/components_base/server/managed_component_base.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Functions

template<typename **Component**, typename **Derived**>
void **intrusive_ptr_add_ref**(*managed_component*<*Component*, *Derived*> *p) noexcept

template<typename **Component**, typename **Derived**>
void **intrusive_ptr_release**(*managed_component*<*Component*, *Derived*> *p) noexcept

template<typename **Component**, typename **Derived**>

class **managed_component**

#include <managed_component_base.hpp> The *managed_component* template is used as an indirection layer for components allowing to gracefully handle the access to non-existing components.

Additionally, it provides memory management capabilities for the wrapping instances, and it integrates the memory management with the AGAS service. Every instance of a *managed_component* gets assigned a global id. The provided memory management allocates the *managed_component* instances from a special heap, ensuring fast allocation and avoids a full network round trip to the AGAS service for each of the allocated instances.

Template Parameters

- **`Component`** – Component type
- **`Derived`** – Most derived component type

Public Types

using **`derived_type`** = *std*::conditional_t<*std*::is_void_v<*Derived*>, *managed_component*, *Derived*>

using **`wrapped_type`** = *Component*

using **`type_holder`** = *Component*

using **`base_type_holder`** = typename *Component*::base_type_holder

using **`heap_type`** = detail::wrapper_heap_list<detail::fixed_wrapper_heap<*derived_type*>>

managed_component &**`operator=`**`(`*managed_component*&&`)` = delete

inline explicit **`managed_component`**`(`*Component* *comp`)`

Construct a *managed_component* instance holding a wrapped instance. This constructor takes ownership of the passed pointer.

Parameters

`comp` – [in] The pointer to the wrapped instance. The *managed_component* takes ownership of this pointer.

inline **`managed_component`**`()`

template<typename **`T`**, typename ...**`Ts`**, typename **`Enable`** = *std*::enable_if_t<!*std*::is_same_v<*std*::decay_t<*T*>, *managed_component*>>>
inline explicit **`managed_component`**`(`*T* &&t, *Ts*&&... ts`)`

inline **`~managed_component`**`()`

inline constexpr *Component* ***`get`**`()` noexcept

Return a pointer to the wrapped instance.

Note

Caller must check validity of returned pointer

Public Types

using **type** = typename *traits*::promise_local_result<typename *hpx*::*traits*::extract_action<*Action*>::remote_result_type>::type

hpx/distribution_policies/colocating_distribution_policy.hpp

Defined in header hpx/distribution_policies/colocating_distribution_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`components`**

Variables

colocating_distribution_policy const **`colocated`**

A predefined instance of the co-locating *distribution_policy*. It will represent the local locality and will place all items to create here.

struct **`colocating_distribution_policy`**

#include <colocating_distribution_policy.hpp> This class specifies the parameters for a distribution policy to use for creating a given number of items on the locality where a given object is currently placed.

Public Functions

constexpr **`colocating_distribution_policy`**`()` = default

Default-construct a new instance of a colocating_distribution_policy. This policy will represent the local locality.

inline *colocating_distribution_policy* **`operator()`**`(`*id_type* const &id`)` const

Create a new colocating_distribution_policy representing the locality where the given object is current located

Parameters

`id` – [in] The global address of the object with which the new instances should be colocated on

template<typename **`Client`**, typename **`Stub`**, typename **`Data`**>
inline *colocating_distribution_policy* **`operator()`**`(`*client_base*<*Client*, *Stub*, *Data*> const &client`)` const

Create a new colocating_distribution_policy representing the locality where the given object is current located

Parameters

`client` – [in] The client side representation of the object with which the new instances should be colocated on

template<typename **`Component`**, typename ...**`Ts`**>
inline *hpx*::*future*<*hpx*::*id_type*> **`create`**`(`*Ts*&&... vs`)` const

Create one object on the locality of the object this distribution policy instance is associated with

Note

This function is part of the placement policy implemented by this class

Parameters
`vs` – [in] The arguments which will be forwarded to the constructor of the new object.

Returns
A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>
inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t count, *Ts*&&... vs) const

Create multiple objects colocated with the object represented by this policy instance

> **Note**
>
> This function is part of the placement policy implemented by this class

Parameters
- `count` – [in] The number of objects to create
- `vs` – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns
A future holding the list of global addresses which represent the newly created objects

template<typename **Action**, typename ...**Ts**>
inline *async_result*<*Action*>::type **async**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Callback**, typename ...**Ts**>
inline *async_result*<*Action*>::type **async_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

> **Note**
>
> This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Continuation**, typename ...**Ts**>
inline bool **apply**(*Continuation* &&c, *launch* policy, *Ts*&&... vs) const

> **Note**
>

template<typename **Action**, typename ...**Ts**>
inline bool **apply**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Continuation**, typename **Callback**, typename ...**Ts**>
inline bool **apply_cb**(*Continuation* &&c, *launch* policy, *Callback* &&cb, *Ts*&&... vs) const

> **Note**
>
> This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Callback**, typename ...**Ts**>
inline bool **apply_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

inline *hpx*::*id_type* **`get_next_target`**`()` const

Returns the locality which is anticipated to be used for the next async operation

Public Static Functions

static inline *std*::size_t **`get_num_localities`**`()`

Returns the number of associated localities for this distribution policy

Note

This function is part of the creation policy implemented by this class

Private Functions

inline *hpx*::*id_type* **`resolve_direct_target`**`()` const

template<typename **`Action`**>

struct **`async_result`**

#include <colocating_distribution_policy.hpp>

Note

This function is part of the invocation policy implemented by this class

Public Types

hpx/distribution_policies/default_distribution_policy.hpp

Defined in header hpx/distribution_policies/default_distribution_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`components`**

Variables

default_distribution_policy const **`default_layout`**

A predefined instance of the default *distribution_policy*. It will represent the local locality and will place all items to create here.

struct **`default_distribution_policy`**

#include <default_distribution_policy.hpp> This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

constexpr **`default_distribution_policy`**`()` = default

Default-construct a new instance of a default_distribution_policy. This policy will represent one locality (the local locality).

inline *default_distribution_policy* **`operator()`**`(`*std*::vector<*id_type*> locs`)` const

Create a new *default_distribution* policy representing the given set of localities.

Parameters

`locs` – [in] The list of localities the new instance should represent

inline *default_distribution_policy* **`operator()`**`(`*id_type* loc`)` const

Create a new *default_distribution* policy representing the given locality

Parameters

`loc` – [in] The locality the new instance should represent

template<typename **`Component`**, typename ...**`Ts`**>
inline *hpx*::*future*<*hpx*::*id_type*> **`create`**`(`*Ts*&&... vs`)` const

Create one object on one of the localities associated by this policy instance

> **Note**
>
> This function is part of the placement policy implemented by this class

Parameters

`vs` – [in] The arguments which will be forwarded to the constructor of the new object.

Returns

A future holding the global address which represents the newly created object

template<bool **`WithCount`**, typename **`Component`**, typename ...**`Ts`**>
inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **`bulk_create`**`(`*std*::size_t count, *Ts*&&... vs`)` const

Create multiple objects on the localities associated by this policy instance

> **Note**
>
> This function is part of the placement policy implemented by this class

Parameters

- **`count`** – [in] The number of objects to create

- `vs` – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns

A future holding the list of global addresses that represent the newly created objects

template<typename **`Action`**, typename ...**`Ts`**>
inline *async_result*<*Action*>::type **`async`**(*launch* policy, *Ts*&&... vs) const

template<typename **`Action`**, typename **`Callback`**, typename ...**`Ts`**>
inline *async_result*<*Action*>::type **`async_cb`**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

Note

This function is part of the invocation policy implemented by this class

template<typename **`Action`**, typename **`Continuation`**, typename ...**`Ts`**>
inline bool **`apply`**(*Continuation* &&c, *launch* policy, *Ts*&&... vs) const

Note

This function is part of the invocation policy implemented by this class

template<typename **`Action`**, typename ...**`Ts`**>
inline bool **`apply`**(*threads*::*thread_priority* priority, *Ts*&&... vs) const

template<typename **`Action`**, typename **`Continuation`**, typename **`Callback`**, typename ...**`Ts`**>
inline bool **`apply_cb`**(*Continuation* &&c, *launch* policy, *Callback* &&cb, *Ts*&&... vs) const

Note

This function is part of the invocation policy implemented by this class

template<typename **`Action`**, typename **`Callback`**, typename ...**`Ts`**>
inline bool **`apply_cb`**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

inline *std*::size_t **`get_num_localities`**() const

Returns the number of associated localities for this distribution policy

Note

This function is part of the creation policy implemented by this class

inline *hpx*::*id_type* **`get_next_target`**() const

Returns the locality which is anticipated to be used for the next async operation

template<typename **`Action`**>

struct **`async_result`**

#include <default_distribution_policy.hpp>

> **Note**

Public Types

using **type** = *hpx*::*future*<typename *traits*::promise_local_result<typename *hpx*::*traits*::extract_action<*Action*>::remote_result_type>::type>

hpx/distribution_policies/binpacking_distribution_policy.hpp

Defined in header hpx/distribution_policies/binpacking_distribution_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Variables

constexpr char const *const **default_binpacking_counter_name** = "/runtime{locality/total}/count/component@"

binpacking_distribution_policy const **binpacked**

A predefined instance of the binpacking *distribution_policy*. It will represent the local locality and will place all items to create here.

struct **binpacking_distribution_policy**

#include <binpacking_distribution_policy.hpp> This class specifies the parameters for a binpacking distribution policy to use for creating a given number of items on a given set of localities. The binpacking policy will distribute the new objects in a way such that each of the localities will equalize the number of overall objects of this type based on a given criteria (by default this criteria is the overall number of objects of this type).

Public Functions

inline **binpacking_distribution_policy**()

Default-construct a new instance of a binpacking_distribution_policy. This policy will represent one locality (the local locality).

inline *binpacking_distribution_policy* **operator()**(*std*::vector<*id_type*> const &locs, char const *perf_counter_name = *default_binpacking_counter_name*) const

Create a new *default_distribution* policy representing the given set of localities.

Parameters

- **`locs`** – [in] The list of localities the new instance should represent
- **`perf_counter_name`** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

inline *binpacking_distribution_policy* **`operator()`**(*std*::vector<*id_type*> &&locs, char const *perf_counter_name = *default_binpacking_counter_name*) const

Create a new *default_distribution* policy representing the given set of localities.

Parameters

- **`locs`** – [in] The list of localities the new instance should represent
- **`perf_counter_name`** – [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

inline *binpacking_distribution_policy* **`operator()`**(*id_type* const &loc, char const *perf_counter_name = *default_binpacking_counter_name*) const

Create a new *default_distribution* policy representing the given locality

Parameters

- **`loc`** – [in] The locality the new instance should represent
- **`perf_counter_name`** – [in] The name of the performance counter that should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

template<typename **`Component`**, typename ...**`Ts`**>
inline *hpx*::*future*<*hpx*::*id_type*> **`create`**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

Parameters

`vs` – [in] The arguments which will be forwarded to the constructor of the new object.

Returns

A future holding the global address which represents the newly created object

template<bool **`WithCount`**, typename **`Component`**, typename ...**`Ts`**>
inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **`bulk_create`**(*std*::size_t count, *Ts*&&... vs) const

Create multiple objects on the localities associated by this policy instance

Parameters

- **`count`** – [in] The number of objects to create
- **`vs`** – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns

A future holding the list of global addresses which represent the newly created objects

inline *std*::string const &**`get_counter_name`**() const

Returns the name of the performance counter associated with this policy instance.

inline *std*::size_t **`get_num_localities`**() const

Returns the number of associated localities for this distribution policy

> **Note**
>
> This function is part of the creation policy implemented by this class

hpx/distribution_policies/target_distribution_policy.hpp

Defined in header hpx/distribution_policies/target_distribution_policy.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Variables

target_distribution_policy const **target**

A predefined instance of the target_distribution_policy. It will represent the local locality and will place all items to create here.

struct **target_distribution_policy**

#include <target_distribution_policy.hpp> This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

target_distribution_policy() = default

Default-construct a new instance of a target_distribution_policy. This policy will represent one locality (the local locality).

inline *target_distribution_policy* **operator()**(*id_type* const &id) const

Create a new target_distribution_policy representing the given locality

Parameters

id – [in] The locality the new instance should represent

template<typename **Component**, typename ...**Ts**>
inline *hpx*::*future*<*hpx*::*id_type*> **create**(*Ts*&&... vs) const

Create one object on one of the localities associated by this policy instance

Note

This function is part of the placement policy implemented by this class

Parameters

vs – [in] The arguments which will be forwarded to the constructor of the new object.

Returns

A future holding the global address which represents the newly created object

template<bool **WithCount**, typename **Component**, typename ...**Ts**>
inline *hpx*::*future*<*std*::vector<bulk_locality_result>> **bulk_create**(*std*::size_t count, *Ts*&&... vs) const

Create multiple objects on the localities associated by this policy instance

Note

This function is part of the placement policy implemented by this class

Parameters

- **`count`** – [in] The number of objects to create
- **`vs`** – [in] The arguments which will be forwarded to the constructors of the new objects.

Returns

A future holding the list of global addresses which represent the newly created objects

template<typename **Action**, typename ...**Ts**>
inline *async_result*<*Action*>::type **async**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Callback**, typename ...**Ts**>
inline *async_result*<*Action*>::type **async_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

Note

This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Continuation**, typename ...**Ts**>
inline bool **apply**(*Continuation* &&c, *launch* policy, *Ts*&&... vs) const

Note

This function is part of the invocation policy implemented by this class

template<typename **Action**, typename ...**Ts**>
inline bool **apply**(*launch* policy, *Ts*&&... vs) const

template<typename **Action**, typename **Continuation**, typename **Callback**, typename ...**Ts**>
inline bool **apply_cb**(*Continuation* &&c, *launch* policy, *Callback* &&cb, *Ts*&&... vs) const

Note

This function is part of the invocation policy implemented by this class

template<typename **Action**, typename **Callback**, typename ...**Ts**>
inline bool **apply_cb**(*launch* policy, *Callback* &&cb, *Ts*&&... vs) const

inline *std*::size_t **get_num_localities**() const

Returns the number of associated localities for this distribution policy

Note

This function is part of the creation policy implemented by this class

inline *hpx*::*id_type* **get_next_target**() const

Returns the locality which is anticipated to be used for the next async operation template<typename **Action**>

struct **async_result**

#include <target_distribution_policy.hpp>

Note

This function is part of the invocation policy implemented by this class

Public Types

using **type** = *hpx*::*future*<typename *traits*::promise_local_result<typename *hpx*::*traits*::extract_action<*Action*>::remote_result_type>::type>

execution_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/execution_distributed/distributed_scheduler.hpp

Defined in header hpx/execution_distributed/distributed_scheduler.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

P2300-compliant scheduler for cross-locality execution.

Provides a scheduler that dispatches work to a remote HPX locality via the parcelport, bridging the hpx::future completion back into the P2300 set_value / set_error receiver protocol.

Usage:

```
hpx::id_type remote = hpx::find_all_localities()[1];
auto sched = hpx::distributed::distributed_scheduler{remote};
auto result = ex::just(42)
    | ex::continues_on(sched)
    | ex::then([](int x){ return x * 2; })
    | tt::sync_wait();
```

hpx/execution_distributed/distributed_then_sender.hpp

Defined in header hpx/execution_distributed/distributed_then_sender.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Placeholder for the distributed then sender adaptor.

A proper component-based receiver marshalling system (nvexec-style) will be implemented here in a future phase.

hpx/execution_distributed/distributed_bulk_sender.hpp

Defined in header hpx/execution_distributed/distributed_bulk_sender.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

P2300-compliant distributed bulk sender adaptor.

Provides a bulk sender that executes data-parallel work on a remote HPX locality via the distributed_scheduler. The sender intercepts ex::bulk() when the upstream sender's completion scheduler is a distributed_scheduler, and dispatches a shape-indexed invocation across the parcelport.

Architecture: upstream_sender | v ex::bulk(shape, f) | (completion scheduler == distributed_scheduler) v distributed_bulk_sender<Sender, Shape, F> | v (connect + start) local_receiver wraps downstream_receiver | set_value(Ts…) | => for each index in shape: invoke f(index, ts…) | => forward set_value(ts…) to downstream v downstream_receiver

Note

Current status: local-only stub. The bulk loop executes sequentially on the calling locality. Remote parcelport dispatch will be added once the component-based receiver marshalling infrastructure (nvexec-style) is complete.

hpx/execution_distributed/distributed_continues_on_sender.hpp

Defined in header hpx/execution_distributed/distributed_continues_on_sender.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

Placeholder for the distributed continues_on sender adaptor.

A proper component-based receiver marshalling system (nvexec-style) will be implemented here in a future phase.

executors_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/executors_distributed/distribution_policy_executor.hpp

Defined in header hpx/executors_distributed/distribution_policy_executor.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **execution**

namespace **experimental**

Functions

template<typename **DistPolicy**>
distribution_policy_executor(*DistPolicy*&&) -> *distribution_policy_executor*<*std*::decay_t<*DistPolicy*>>

template<typename **DistPolicy**>
distribution_policy_executor<*std*::decay_t<*DistPolicy*>> **make_distribution_policy_executor**(*DistPolicy* &&policy)

Create a new *distribution_policy_executor* from the given distribution_policy.

Parameters

policy – The distribution_policy to create an executor from

template<typename **DistPolicy**>

class **distribution_policy_executor**

#include <distribution_policy_executor.hpp> A distribution_policy_executor creates groups of parallel execution agents that execute in threads implicitly created by the executor and placed on any of the associated localities.

Template Parameters

DistPolicy – The distribution policy type for which an executor should be created. The expression *hpx::traits::is_distribution_policy_v<DistPolicy>* must evaluate to true.

init_runtime

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/hpx_init.hpp

Defined in header hpx/hpx_init.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

hpx/hpx_start.hpp

Defined in header hpx/hpx_start.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

hpx::init_params

Defined in header hpx/init.hpp[1015].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

struct **`init_params`**

Parameters used to initialize the HPX runtime through hpx::init and hpx::start.

hpx::init

Defined in header hpx/init.hpp[1016].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

inline int *`hpx`*`::`**`init`**(*std*::function<int(*hpx*::program_options::variables_map&)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **`f`** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **`argc`** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **`argv`** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **`params`** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from the user supplied `f`.

[1015] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/init_runtime/include/hpx/init.hpp

[1016] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/init_runtime/include/hpx/init.hpp

inline int *hpx*::**init**(*std*::function<int(int, char**)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **`f`** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **`argc`** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **`argv`** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **`params`** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from the user supplied `f`.

inline int *hpx*::**init**(int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads) should be called from the users `main()` function. This overload expects a user-defined function named `hpx_main` at global scope, which will be used as the entry point for the HPX application.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

> **Note**
>
> If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **`argc`** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **`argv`** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **`params`** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from `hpx_main` (or 0 when executed in worker mode).

inline int *hpx*::**init**(*std*::nullptr_t f, int argc, char **argv, *init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

Note

If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **`f`** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **`argc`** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **`argv`** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **`params`** – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from the user supplied `f`.

inline int *hpx*::**init**(*init_params* const &params = *init_params*())

Main entry point for launching the HPX runtime system.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings). This overload expects a user-defined function named `hpx_main` at global scope, which will be used as the entry point for the HPX application.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

> **Note**
>
> The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. If not command line arguments are passed, console mode is assumed.

> **Note**
>
> If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

Parameters

`params` – [in] The parameters to the hpx::init function (See documentation of hpx::init_params)

Returns

The function returns the value, which has been returned from `hpx_main` (or 0 when executed in worker mode).

hpx::suspend

Defined in header hpx/init.hpp[1017].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::resume*

int `hpx::`**`suspend`**(*error_code* &ec = *throws*)

Suspend the runtime system.

The function hpx::suspend is used to suspend the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be empty. This function only be called when the runtime is running, or already suspended in which case this function will do nothing.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

[1017] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/init_runtime/include/hpx/init.hpp

hpx::resume

Defined in header hpx/init.hpp[1018].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::suspend*

int **hpx::resume**(*error_code* &ec = *throws*)

Resume the HPX runtime system.

The function hpx::resume is used to resume the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be resumed. This function only be called when the runtime suspended, or already running in which case this function will do nothing.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

hpx::start

Defined in header hpx/init.hpp[1019].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

inline bool **hpx::start**(*std*::function<int(*hpx*::program_options::variables_map&)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system's execution. This overload will not call `hpx_main`.

Note

If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc`/`argv`. Otherwise, it will be executed as specified by the parameter`mode`.

Parameters

- **`f`** – [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- **`argc`** – [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- **`argv`** – [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- **`params`** – [in] The parameters to the hpx::start function (See documentation of hpx::init_params)

Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

inline bool `hpx::start`(*std*::function<int(int, char**)> f, int argc, char **argv, *init_params* const &params = *init_params*())

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. It will return immediately after that. > **Note**
>
> If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

Parameters

`params` – [in] The parameters to the hpx::start function (See documentation of hpx::init_params)

Returns

The function returns *true* if command line processing succeeded and the runtime system was started successfully. It will return *false* otherwise.

hpx::finalize

Defined in header hpx/init.hpp[1020].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::disconnect*

int `hpx::finalize`(double shutdown_timeout, double local_wait, *hpx*::*error_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function hpx::finalize is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on all localities.

The value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter `hpx.shutdown_timeout`), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The value (`-1.0`) will try to find a globally set wait time value (can be set as the configuration parameter "hpx.finalize_wait_time"), and if this is not set or `-1.0` as well, it will disable any addition local wait time before proceeding.

This function will not wait for all connected localities to exit, rather it informs all connected localities that they should exit whenever there is no more work to be done.

Using this function is an alternative to hpx::disconnect, these functions do not need to be called both.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

> **Note**
>
> This overload is deprecated, use the overload taking *hpx::chrono::steady_duration* arguments instead.

[1020] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/init_runtime/include/hpx/init.hpp

Parameters

- **`shutdown_timeout`** – This parameter allows to specify a timeout (in seconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **`local_wait`** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

int *hpx*::**finalize**(double shutdown_timeout, *hpx*::*error_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function hpx::finalize is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on all localities.

The value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter `hpx.shutdown_timeout`), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

This function will not wait for all connected localities to exit, rather it informs all connected localities that they should exit whenever there is no more work to be done.

Using this function is an alternative to hpx::disconnect, these functions do not need to be called both.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Note

This overload is deprecated, use the overload taking *hpx::chrono::steady_duration* arguments instead.

Parameters

- **`shutdown_timeout`** – This parameter allows to specify a timeout (in seconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

int `hpx::finalize`(*hpx*::*error_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function hpx::finalize is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on all localities.

This function will not wait for all connected localities to exit, rather it informs all connected localities that they should exit whenever there is no more work to be done.

Using this function is an alternative to hpx::disconnect, these functions do not need to be called both.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

int `hpx::finalize`(*hpx*::chrono::*steady_duration* shutdown_timeout, *hpx*::*error_code* &ec = *throws*)

Main function to gracefully terminate the HPX runtime system.

The function hpx::finalize is the main way to (gracefully) exit any HPX application. It must be called at least once, but can be called multiple times as well. However, only the first invocation will have effect. It will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on all localities.

Any std::chrono::duration is implicitly convertible to *hpx::chrono::steady_duration*, e.g. `hpx::finalize(std::chrono::seconds(60))`. Pass the timeout explicitly to use it; call the overload taking no arguments to use the globally configured default (see configuration parameter `hpx.shutdown_timeout`).

This function will not wait for all connected localities to exit, rather it informs all connected localities that they should exit whenever there is no more work to be done.

Using this function is an alternative to hpx::disconnect, these functions do not need to be called both.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

- `shutdown_timeout` – This parameter allows to specify a timeout, specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

hpx::disconnect

Defined in header hpx/init.hpp[1021].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::finalize*

int `hpx::disconnect`(double shutdown_timeout, double localwait, *hpx*::*error_code* &ec = *throws*)

Disconnect this locality from the application.

The function hpx::disconnect can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on this locality.

The value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter "hpx.shutdown_timeout"), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

The value (`-1.0`) will try to find a globally set wait time value (can be set as the configuration parameter `hpx.finalize_wait_time`), and if this is not set or `-1.0` as well, it will disable any addition local wait time before proceeding.

This function will not wait for this locality to finish executing, rather it informs this locality that it should disconnect whenever there is no more work to be done.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

[1021] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/init_runtime/include/hpx/init.hpp

> **Note**
>
> This overload is deprecated, use the overload taking *hpx::chrono::steady_duration* arguments instead.

Parameters

- **`shutdown_timeout`** – This parameter allows to specify a timeout (in seconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **`localwait`** – This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

int `hpx::`**`disconnect`**(double shutdown_timeout, *hpx*::*error_code* &ec = *throws*)

Disconnect this locality from the application.

The function hpx::disconnect can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on this locality.

The value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter "hpx.shutdown_timeout"), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

This function will not wait for this locality to finish executing, rather it informs this locality that it should disconnect whenever there is no more work to be done.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

> **Note**
>
> This overload is deprecated, use the overload taking *hpx::chrono::steady_duration* arguments instead.

Parameters

- **`shutdown_timeout`** – This parameter allows to specify a timeout (in seconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero if successful, -1 otherwise.

int `hpx::disconnect`(*hpx*::*error_code* &ec = *throws*)

Disconnect this locality from the application.

The function hpx::disconnect can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on this locality.

This function will not wait for this locality to finish executing, rather it informs this locality that it should disconnect whenever there is no more work to be done.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero if successful, -1 otherwise.

int `hpx::disconnect`(*hpx*::chrono::*steady_duration* shutdown_timeout, *hpx*::*error_code* &ec = *throws*)

Disconnect this locality from the application.

The function hpx::disconnect can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on this locality.

Any std::chrono::duration is implicitly convertible to *hpx::chrono::steady_duration*, e.g. `hpx::disconnect(std::chrono::seconds(60))`. Pass the timeout explicitly to use it; call the overload taking no arguments to use the globally configured default (see configuration parameter `hpx.shutdown_timeout`).

This function will not wait for this locality to finish executing, rather it informs this locality that it should disconnect whenever there is no more work to be done.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of *hpx::exception*.

Parameters

- **`shutdown_timeout`** – This parameter allows to specify a timeout, specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

This function will always return zero.

naming_base

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/naming_base/unmanaged.hpp

Defined in header hpx/naming_base/unmanaged.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

Functions

hpx::*id_type* **`unmanaged`**(*hpx*::*id_type* const &id)

The helper function *hpx::unmanaged* can be used to generate a global identifier which does not participate in the automatic garbage collection.

Note

This function allows to apply certain optimizations to the process of memory management in HPX. It however requires the user to take full responsibility for keeping the referenced objects alive long enough.

Parameters

`id` – [in] The id to generated the unmanaged global id from This parameter can be itself a managed or a unmanaged global id.

Returns

This function returns a new global id referencing the same object as the parameter *id*. The only difference is that the returned global identifier does not participate in the automatic garbage collection.

namespace **`hpx`**

namespace **`plugins`**

template<typename **`BinaryFilter`**>

struct **`binary_filter_factory`** : public binary_filter_factory_base

#include <binary_filter_factory.hpp> The *message_handler_factory* provides a minimal implementation of a message handler's factory. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a message handler's factory instance.

Template Parameters

`BinaryFilter` – The message handler type this factory should be responsible for.

Public Functions

inline **binary_filter_factory**(*util*::section const *global, *util*::section const *local, bool isenabled)

Construct a new factory instance.

> **Note**
>
> The contents of both sections has to be cloned in order to save the configuration setting for later use.

Parameters
- **global** – [in] The pointer to a *hpx::util::section* instance referencing the settings read from the [settings] section of the global configuration file (hpx.ini) This pointer may be nullptr if no such section has been found.
- **local** – [in] The pointer to a *hpx::util::section* instance referencing the settings read from the section describing this component type: [hpx.components.<name>], where <name> is the instance name of the component as given in the configuration files.
- **isenabled** –

~binary_filter_factory() override = default

inline *serialization*::binary_filter ***create**(bool compress, *serialization*::binary_filter *next_filter = nullptr) override

Create a new instance of a message handler

return Returns the newly created instance of the message handler supported by this factory

Protected Attributes

util::section **global_settings_**

util::section **local_settings_**

bool **isenabled_**

hpx/plugin_factories/message_handler_factory.hpp

Defined in header hpx/plugin_factories/message_handler_factory.hpp.

hpx/plugin_factories/plugin_registry.hpp

Defined in header hpx/plugin_factories/plugin_registry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **plugins**

template<typename **Plugin**, char const *const **Name**, char const *const **Section**, char const *const **Suffix**>
struct **plugin_registry** : public *plugin_registry_base*

#include <plugin_registry.hpp> The plugin_registry provides a minimal implementation of a plugin's registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a plugin's registry instance.

Template Parameters

Plugin – The plugin type this registry should be responsible for.

Public Functions

inline bool **get_plugin_info**(*std*::vector<*std*::string> &fillini) override

Return the ini-information for all contained components.

Parameters

fillini – [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

resiliency_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/resiliency_distributed/async_replicate_distributed.hpp

Defined in header hpx/resiliency_distributed/async_replicate_distributed.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **resiliency**

namespace **experimental**

Functions

template<typename **Vote**, typename **Pred**, typename **Action**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replicate_vote_validate_t*, *std*::vector<*hpx*::*id_type*> const &ids, *Vote* &&vote, *Pred* &&pred, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate_vote_validate CPO.

Asynchronously launches *action* on each locality in *ids*, validates results with *pred*, then runs valid results through *vote*.

The CPO tag is `async_replicate_vote_validate_t`.

Parameters

- **ids** – Target localities (one invocation per locality).
- **vote** – Voting function selecting among valid results.
- **pred** – Predicate validating each invocation result.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the voted-upon result.

template<typename **Vote**, typename **Action**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replicate_vote_t*, *std*::vector<*hpx*::*id_type*> const &ids, *Vote* &&vote, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate_vote CPO.

Asynchronously launches *action* on each locality in *ids*, runs valid results through *vote*. Validation uses the default exception check.

The CPO tag is `async_replicate_vote_t`.

Parameters

- **ids** – Target localities (one invocation per locality).
- **vote** – Voting function selecting among valid results.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the voted-upon result.

template<typename **Pred**, typename **Action**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replicate_validate_t*, *std*::vector<*hpx*::*id_type*> const &ids, *Pred* &&pred, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate_validate CPO.

Asynchronously launches *action* on each locality in *ids*, validates results with *pred*. Returns the first valid result.

The CPO tag is `async_replicate_validate_t`.

Parameters

- **ids** – Target localities (one invocation per locality).
- **pred** – Predicate validating each invocation result.
- **action** – Action to invoke on each locality.
- **ts** – Arguments forwarded to *action*.

Returns

future with the first valid result.

template<typename **Action**, typename ...**Ts**>
decltype(auto) **hpx_invoke**(*async_replicate_t*, *std*::vector<*hpx*::*id_type*> const &ids, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replicate CPO.

Asynchronously launches *action* on each locality in *ids*. Validates by checking for exceptions. Returns the first valid result.

The CPO tag is `async_replicate_t`.

Parameters

- **`ids`** – Target localities (one invocation per locality).
- **`action`** – Action to invoke on each locality.
- **`ts`** – Arguments forwarded to *action*.

Returns

future with the first non-throwing result.

hpx/resiliency_distributed/async_replay_distributed.hpp

Defined in header hpx/resiliency_distributed/async_replay_distributed.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`resiliency`**

namespace **`experimental`**

Functions

template<typename **`Action`**, typename ...**`Ts`**>
hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*Action*, *hpx*::*id_type*, *Ts*...>> **`hpx_invoke`**(*async_replay_t*, *std*::vector<*hpx*::*id_* const &ids, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replay CPO.

Asynchronously launches *action* on localities in *ids*, replaying on the next locality on error (aborts on abort_replay_exception).

The CPO tag is `async_replay_t`.

Parameters

- **`ids`** – Target localities to try in order.
- **`action`** – Action to invoke on each locality.
- **`ts`** – Arguments forwarded to *action*.

Returns

future with the first successful result.

template<typename **`Pred`**, typename **`Action`**, typename ...**`Ts`**>

hpx::*future*<*hpx*::*util*::detail::invoke_deferred_result_t<*Action*, *hpx*::*id_type*, *Ts*...>> **`hpx_invoke`**(*async_replay_valid* *std*::vector<*hpx*::*id_* const &ids, *Pred* &&pred, *Action* &&action, *Ts*&&... ts)

ADL hook for distributed async_replay_validate CPO.

Asynchronously launches *action* on localities in *ids*, validating results with *pred*. Replays on the next locality on error (aborts on abort_replay_exception).

The CPO tag is `async_replay_validate_t`.

Parameters

- **`ids`** – Target localities to try in order.
- **`pred`** – Predicate validating each invocation result.
- **`action`** – Action to invoke on each locality.
- **`ts`** – Arguments forwarded to *action*.

Returns

future with the first valid result.

namespace **components**

hpx::new_

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *local_new*

template<typename **Component**, typename ...**Ts**>
auto *hpx*::**new_**(*id_type* const &locality, *Ts*&&... vs)

Create one or more new instances of the given Component type on the specified locality.

This function creates one or more new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
   hpx::new_<some_component>(hpx::find_here(), ...);
hpx::id_type id = f.get();
```

Parameters

- **locality** – [in] The global address of the locality where the new instance should be created on.

- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

template<typename **Component**, typename ...**Ts**>
auto *hpx*::**new_**(*id_type* const &locality, *std*::size_t count, *Ts*&&... vs)

Create multiple new instances of the given Component type on the specified locality.

This function creates multiple new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type> > f =
   hpx::new_<some_component[]>(hpx::find_here(), 10, ...);
hpx::id_type id = f.get();
```

Parameters

- **locality** – [in] The global address of the locality where the new instance should be created on.
- **count** – [in] The number of component instances to create
- **vs** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. *Component*[], where `traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument *Component* represents an array of a client side object type (i.e. *Component*[], where `traits::is_client<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

template<typename **Component**, typename **DistPolicy**, typename ...**Ts**>

auto *hpx*::**new_**(*DistPolicy* const &policy, *Ts*&&... vs)

Create one or more new instances of the given Component type based on the given distribution policy.

This function creates one or more new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for global address which can be used to reference the new component instance(s).

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
   hpx::new_<some_component>(hpx::default_layout, ...);
hpx::id_type id = f.get();
```

Parameters

- **`policy`** – [in] The distribution policy used to decide where to place the newly created.
- **`vs`** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

template<typename **Component**, typename **DistPolicy**, typename ...**Ts**>
auto *hpx*::**new_**(*DistPolicy* const &policy, *std*::size_t count, *Ts*&&... vs)

Create multiple new instances of the given Component type on the localities as defined by the given distribution policy.

This function creates multiple new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for the global address which can be used to reference the new component instance.

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<std::vector<hpx::id_type> > f =
   hpx::new_<some_component[]>(hpx::default_layout, 10, ...);
hpx::id_type id = f.get();
```

Parameters

- **`policy`** – [in] The distribution policy used to decide where to place the newly created.
- **`count`** – [in] The number of component instances to create
- **`vs`** – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents an array of a component type (i.e. *Component*[], where `traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument *Component* represents an array of a client side object type (i.e. *Component*[], where `traits::is_client<Component>::value` evaluates to true), the function will return an hpx::future object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

local_new

Defined in header hpx/components.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::new_*

template<typename **Component**, typename ...**Ts**>
auto *hpx*::**local_new**(*Ts*&&... vs)

Create one new instance of the given Component type on the current locality.

This function creates one new instance of the given Component type on the current locality and returns a future object for the global address which can be used to reference the new component instance.

Note

This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```
hpx::future<hpx::id_type> f =
   hpx::local_new<some_component>(...);
hpx::id_type id = f.get();
```

Note

The difference of this function to hpx::new_ is that it can be used in cases where the supplied arguments are non-copyable and non-movable. All operations are guaranteed to be local only.

Parameters

`vs` – [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Returns

The function returns different types depending on its use:

- If the explicit template argument *Component* represents a component type (`traits::is_component<Component>::value` evaluates to true), the function will return an hpx::future object instance which can be used to retrieve the global address of the newly created component. If the first argument is `hpx::launch::sync` the function will directly return an *`hpx::id_type`*.
- If the explicit template argument *Component* represents a client side object (`traits::is_client<Component>::value` evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

hpx/runtime_components/component_registry.hpp

Defined in header hpx/runtime_components/component_registry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`components`**

template<typename **`Component`**, *factory_state* **`state`**>

struct **`component_registry`** : public *component_registry_base*

#include <component_registry.hpp> The component_registry provides a minimal implementation of a component's registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a component's registry instance.

Template Parameters

`Component` – The component type this registry should be responsible for.

Public Functions

inline bool **`get_component_info`**(*std*::vector<*std*::string> &fillini, *std*::string const &filepath, bool is_static = false) override

Return the ini-information for all contained components.

Parameters

- **`fillini`** – [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.
- **`filepath`** –
- **`is_static`** –

Returns

Returns *true* if the parameter *fillini* has been successfully initialized with the registry data of all implemented in this module.

inline void **`register_component_type`**() override

Enables this type of registry and sets its destroy mechanism.

hpx/runtime_components/macros.hpp

Defined in header hpx/runtime_components/macros.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

runtime_distributed

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/runtime_distributed.hpp

Defined in header hpx/runtime_distributed.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

class **`runtime_distributed`** : public *runtime*

#include <runtime_distributed.hpp> The *runtime* class encapsulates the HPX runtime system in a simple to use way. It makes sure all required parts of the HPX runtime system are properly initialized.

Public Functions

explicit **`runtime_distributed`**(*util*::*runtime_configuration* &rtcfg, int (*pre_main)(*runtime_mode*) = nullptr, void (*post_main)() = nullptr)

Construct a new HPX runtime instance

Parameters

- **`rtcfg`** – Runtime configuration for this instance
- **`pre_main`** – Function to be called before running the main action of this instance
- **`post_main`** – Function to be called after running the main action of this instance

`~runtime_distributed`()

The destructor makes sure all HPX runtime services are properly shut down before exiting.

int **`start`**(*hpx*::*function*<hpx_main_function_type> const &func, bool blocking = false) override

Start the runtime system.

Parameters

- **`func`** – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*.
- **`blocking`** – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally.

Returns

If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

int **`start`**(bool blocking = false) override

Start the runtime system.

Parameters

`blocking` – [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is *true* the function *runtime::start* will call *runtime::wait* internally .

Returns

If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

int **`wait`**() override

Wait for the shutdown action to be executed.

Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

void **stop**(bool blocking = true) override

Initiate termination of the runtime system.

Parameters

blocking – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.

int **finalize**(double shutdown_timeout) override

void **stop_helper**(bool blocking, *std*::condition_variable &cond, *std*::mutex &mtx)

Stop the runtime system, wait for termination.

Parameters

- **blocking** – [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is *false* then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to *true* to wait for all internal work to be completed.
- **cond** – Condition used to update all thread when done
- **mtx** – Mutex used by this function to sync all threads

int **suspend**() override

Suspend the runtime system.

int **resume**() override

Resume the runtime system.

bool **report_error**(*std*::size_t num_thread, *std*::exception_ptr const &e, bool terminate_all = true) override

Report a non-recoverable error to the runtime system.

Parameters

- **num_thread** – [in] The number of the operating system thread the error has been detected in.
- **e** – [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate_all** – [in] Kill all localities attached to the currently running application (default: true)

bool **report_error**(*std*::exception_ptr const &e, bool terminate_all = true) override

Report a non-recoverable error to the runtime system.

Note

This function will retrieve the number of the current shepherd thread and forward to the report_error function above.

Parameters

- **e** – [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate_all** – [in] Kill all localities attached to the currently running application (default: true)

int **run**(*hpx*::*function*<hpx_main_function_type> const &func) override

Run the HPX runtime system, use the given function for the main *thread* and block waiting for all threads to finish.

Note

The parameter *func* is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

Parameters

`func` – [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef *hpx_main_function_type*. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

Returns

This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

int **run**() override

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

Returns

This function will always return 0 (zero).

bool **is_networking_enabled**() override

template<typename **F**>
inline *components*::*server*::console_error_dispatcher::sink_type **set_error_sink**(*F* &&sink)

performance_counters::registry &**get_counter_registry**()

Allow access to the registry counter registry instance used by the HPX runtime.

performance_counters::registry const &**get_counter_registry**() const

Allow access to the registry counter registry instance used by the HPX runtime.

void **register_query_counters**(*std*::shared_ptr<*util*::query_counters> const &active_counters)

void **start_active_counters**(*error_code* &ec = *throws*) const

void **stop_active_counters**(*error_code* &ec = *throws*) const

void **reset_active_counters**(*error_code* &ec = *throws*) const

void **reinit_active_counters**(bool reset = true, *error_code* &ec = *throws*) const

void **evaluate_active_counters**(bool reset = false, char const *description = nullptr, *error_code* &ec = *throws*) const

void **stop_evaluating_counters**(bool terminate = false) const

agas::*addressing_service* &**get_agas_client**()

Allow access to the AGAS client instance used by the HPX runtime.

hpx::*threads*::*threadmanager* &**get_thread_manager**() override

Allow access to the thread manager instance used by the HPX runtime.

applier::*applier* &**get_applier**()

Allow access to the applier instance used by the HPX runtime.

std::string **`here`**`()` const override

Returns a string of the locality endpoints (usable in debug output)

naming::address_type **`get_runtime_support_lva`**`()` const

naming::*gid_type* **`get_next_id`**`(`*std*::size_t count = 1`)`

void **`init_id_pool_range`**`()`

util::unique_id_ranges &**`get_id_pool`**`()`

void **`initialize_agas`**`()`

Initialize AGAS operation.

void **`add_pre_startup_function`**`(`*startup_function_type* `f)` override

Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with *add_startup_function*.

> **Note**
>
> The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

Parameters

`f` – The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void **`add_startup_function`**`(`*startup_function_type* `f)` override

Add a function to be executed inside a HPX thread before hpx_main

Parameters

`f` – The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void **`add_pre_shutdown_function`**`(`*shutdown_function_type* `f)` override

Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

> **Note**
>
> The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

Parameters

`f` – The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

void **`add_shutdown_function`**`(`*shutdown_function_type* `f)` override

Add a function to be executed inside a HPX thread during hpx::finalize

Parameters

`f` – The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

hpx::*util*::*io_service_pool* ***get_thread_pool**(char const *name) override

Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks. The three possible values for the argument `name` are "main_pool", "io_pool", "parcel_pool", and "timer_pool". For any other argument value the function will return zero.

bool **register_thread**(char const *name, *std*::size_t num = 0, bool service_thread = true, *error_code* &ec = *throws*) override

Register an external OS-thread with HPX.

notification_policy_type **get_notification_policy**(char const *prefix, runtime_local::os_thread_type type) override

Generate a new notification policy instance for the given thread name prefix

std::uint32_t **get_locality_id**(*error_code* &ec) const override

std::size_t **get_num_worker_threads**() const override

std::uint32_t **get_num_localities**(*hpx*::*launch*::sync_policy, *error_code* &ec) const override

std::uint32_t **get_initial_num_localities**() const override

hpx::*future*<*std*::uint32_t> **get_num_localities**() const override

std::string **get_locality_name**() const override

std::uint32_t **get_num_localities**(*hpx*::*launch*::sync_policy, *components*::*component_type* type, *error_code* &ec) const

hpx::*future*<*std*::uint32_t> **get_num_localities**(*components*::*component_type* type) const

std::uint32_t **assign_cores**(*std*::string const &locality_basename, *std*::uint32_t num_threads) override

std::uint32_t **assign_cores**() override

hpx/runtime_distributed/migrate_component.hpp

Defined in header hpx/runtime_distributed/migrate_component.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Functions

template<typename **Component**, typename **DistPolicy**>
future<*hpx*::*id_type*> **migrate**(*hpx*::*id_type* const &to_migrate, [[maybe_unused]] *DistPolicy* const &policy)

Migrate the given component to the specified target locality

The function *migrate<Component>* will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The client side representation of the component to migrate.
- **policy** – [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- **Component** – Specifies the component type of the component to migrate.
- **DistPolicy** – Specifies the distribution policy to use to determine the destination locality.

Returns

A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

template<typename **Derived**, typename **Stub**, typename **Data**, typename **DistPolicy**>
Derived **migrate**(*client_base*<*Derived*, *Stub*, *Data*> const &to_migrate, *DistPolicy* const &policy)

Migrate the given component to the specified target locality

The function *migrate<Component>* will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The client side representation of the component to migrate.
- **policy** – [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- **Derived** – Specifies the component type of the component to migrate.
- **DistPolicy** – Specifies the distribution policy to use to determine the destination locality.

Returns

A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

template<typename **Component**>
future<*hpx*::*id_type*> **migrate**(*hpx*::*id_type* const &to_migrate, *hpx*::*id_type* const &target_locality)

Migrate the component with the given id to the specified target locality

The function *migrate<Component>* will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The global id of the component to migrate.
- **target_locality** – [in] The locality where the component should be migrated to.

Template Parameters

Component – Specifies the component type of the component to migrate.

Returns

A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

template<typename **Derived**, typename **Stub**, typename **Data**>
Derived **migrate**(*client_base*<*Derived*, *Stub*, *Data*> const &to_migrate, *hpx*::*id_type* const &target_locality)

Migrate the given component to the specified target locality

The function *migrate<Component>* will migrate the component referenced by *to_migrate* to the locality specified with *target_locality*. It returns a future referring to the migrated component instance.

Parameters

- **`to_migrate`** – [in] The client side representation of the component to migrate.
- **`target_locality`** – [in] The id of the locality to migrate this object to.

Template Parameters

`Derived` – Specifies the component type of the component to migrate.

Returns

A client side representation of representing of the migrated component instance. This should be the same as *migrate_to*.

hpx/runtime_distributed/big_boot_barrier.hpp

Defined in header hpx/runtime_distributed/big_boot_barrier.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/runtime_distributed/get_num_localities.hpp

Defined in header hpx/runtime_distributed/get_num_localities.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

Functions

hpx::*future*<*std*::uint32_t> **`get_num_localities`**(*components*::*component_type* t)

Asynchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* asynchronously returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

See also

hpx::find_all_localities, *hpx::get_num_localities*

Note

This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Parameters

`t` – The component type for which the number of connected localities should be retrieved.

std::uint32_t **`get_num_localities`**(*launch*::sync_policy, *components*::*component_type* t, *error_code* &ec = *throws*)

Synchronously return the number of localities which are currently registered for the running application.

The function *get_num_localities* returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

See also

hpx::find_all_localities, *hpx::get_num_localities*

Note

This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

Parameters

- **`t`** – The component type for which the number of connected localities should be retrieved.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx::find_root_locality

Defined in header hpx/runtime.hpp[1022].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_all_localities*
- *hpx::find_remote_localities*

hpx::*id_type* `hpx::`**`find_root_locality`**(*error_code* &ec = *throws*)

Return the global id representing the root locality.

The function find_root_locality() can be used to retrieve the global id usable to refer to the root locality. The root locality is the locality where the main AGAS service is hosted.

See also

hpx::find_all_localities(), hpx::find_locality()

[1022] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id representing the root locality for this application.

hpx::find_all_localities

Defined in header hpx/runtime.hpp[1023].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_root_locality*
- *hpx::find_remote_localities*

std::vector<*hpx*::*id_type*> `hpx::find_all_localities`(*error_code* &ec = *throws*)

Return the list of global ids representing all localities available to this application.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application.

See also

hpx::find_here(), hpx::find_locality()

[1023] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the localities currently available to this application.

std::vector<*hpx*::*id_type*> `hpx::find_all_localities`(*components*::*component_type* type, *error_code* &ec = *throws*)

Return the list of global ids representing all localities available to this application which support the given component type.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application which support the creation of instances of the given component type.

See also

hpx::find_here(), hpx::find_locality()

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

- **`type`** – [in] The type of the components for which the function should return the available localities.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the localities currently available to this application which support the creation of instances of the given component type. If no localities supporting the given component type are currently available, this function will return an empty vector.

hpx::find_remote_localities

Defined in header hpx/runtime.hpp[1024].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::find_root_locality*
- *hpx::find_all_localities*

std::vector<*hpx*::*id_type*> `hpx::`**`find_remote_localities`**(*error_code* &ec = *throws*)

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one).

See also

hpx::find_here(), hpx::find_locality()

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

[1024] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the remote localities currently available to this application.

std::vector<*hpx*::*id_type*> `hpx::find_remote_localities`(*components*::*component_type* type, *error_code* &ec = *throws*)

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one) which support the creation of instances of the given component type.

See also

hpx::find_here(), hpx::find_locality()

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

Note

This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

Parameters

- **`type`** – [in] The type of the components for which the function should return the available remote localities.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global ids representing the remote localities currently available to this application.

hpx/runtime_distributed/find_here.hpp

Defined in header hpx/runtime_distributed/find_here.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

hpx::*id_type* **`find_here`**(*error_code* &ec = *throws*)

Return the global id representing this locality.

The function find_here() can be used to retrieve the global id usable to refer to the current locality.

See also

hpx::find_all_localities(), *hpx::find_locality()*

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise, it throws an instance of hpx::exception.

Note

This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns
The global id representing the locality this function has been called on.

hpx/runtime_distributed/get_locality_name.hpp

Defined in header hpx/runtime_distributed/get_locality_name.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

Functions

future<*std*::string> **`get_locality_name`**(*hpx*::*id_type* const &id)

Return the name of the referenced locality.

This function returns a future referring to the name for the locality of the given id.

> **See also**
>
> *std::string get_locality_name()*

Parameters
`id` – [in] The global id of the locality for which the name should be retrieved

Returns
This function returns the name for the locality of the given id. The name is retrieved from the underlying networking layer and may be different for different parcel ports.

hpx/runtime_distributed/copy_component.hpp

Defined in header hpx/runtime_distributed/copy_component.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`components`**

Functions

template<typename **Component**>
future<*hpx*::*id_type*> **copy**(*hpx*::*id_type* const &to_copy)

Copy given component to the specified target locality.

The function *copy<Component>* will create a copy of the component referenced by *to_copy* on the locality specified with *target_locality*. It returns a future referring to the newly created component instance.

> **Note**
>
> The new component instance is created on the locality of the component instance which is to be copied.

Parameters
`to_copy` – [in] The global id of the component to copy

Template Parameters
`The` – only template argument specifies the component type to create.

Returns
A future representing the global id of the newly (copied) component instance.

template<typename **Component**>
future<*hpx*::*id_type*> **copy**(*hpx*::*id_type* const &to_copy, *hpx*::*id_type* const &target_locality)

Copy given component to the specified target locality.

The function *copy<Component>* will create a copy of the component referenced by *to_copy* on the locality specified with *target_locality*. It returns a future referring to the newly created component instance.

Parameters

- `to_copy` – [in] The global id of the component to copy
- `target_locality` – [in] The locality where the copy should be created.

Template Parameters
`The` – only template argument specifies the component type to create.

Returns
A future representing the global id of the newly (copied) component instance.

template<typename **Derived**, typename **Stub**, typename **Data**>
Derived **copy**(*client_base*<*Derived*, *Stub*, *Data*> const &to_copy, *hpx*::*id_type* const &target_locality = *hpx*::invalid_id)

Copy given component to the specified target locality.

The function *copy* will create a copy of the component referenced by the client side object *to_copy* on the locality specified with *target_locality*. It returns a new client side object future referring to the newly created component instance.

> **Note**
>
> If the second argument is omitted (or is invalid_id) the new component instance is created on the locality of the component instance which is to be copied.

Parameters

- `to_copy` – [in] The client side object representing the component to copy
- `target_locality` – [in, optional] The locality where the copy should be created (default is same locality as source).

Template Parameters

The – only template argument specifies the component type to create.

Returns

A future representing the global id of the newly (copied) component instance.

hpx/runtime_distributed/applier_fwd.hpp

Defined in header hpx/runtime_distributed/applier_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **applier**

Functions

applier &**get_applier**()

The function *get_applier* returns a reference to the (thread specific) applier instance.

applier ***get_applier_ptr**()

The function *get_applier* returns a pointer to the (thread specific) applier instance. The returned pointer is NULL if the current thread is not known to HPX or if the runtime system is not active.

namespace **applier**

The namespace *applier* contains all definitions needed for the class hpx::applier::applier and its related functionality. This namespace is part of the HPX core module.

hpx/runtime_distributed/runtime_fwd.hpp

Defined in header hpx/runtime_distributed/runtime_fwd.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

Functions

runtime_distributed &**get_runtime_distributed**()

runtime_distributed *&**get_runtime_distributed_ptr**()

naming::*gid_type* const &**get_locality**()

The function *get_locality* returns a reference to the locality prefix.

void **start_active_counters**(*error_code* &ec = *throws*)

Start all active performance counters, optionally naming the section of code.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note

The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`reset_active_counters`**(*error_code* &ec = *throws*)

Resets all active performance counters.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note

The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`reinit_active_counters`**(bool reset = true, *error_code* &ec = *throws*)

Re-initialize all active performance counters.

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Note

The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

- **`reset`** – [in] Reset the current values before re-initializing counters (default: true)
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`stop_active_counters`**(*error_code* &ec = *throws*)

Stop all active performance counters.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

`ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

void **`evaluate_active_counters`**(bool reset = false, char const *description = nullptr, *error_code* &ec = *throws*)

Evaluate and output all active performance counters, optionally naming the point in code marked by this function.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

> **Note**
>
> The output generated by this function is redirected to the destination specified by the corresponding command line options (see –hpx:print-counter-destination).

> **Note**
>
> The active counters are those which have been specified on the command line while executing the application (see command line option –hpx:print-counter)

Parameters

- **`reset`** – [in] this is an optional flag allowing to reset the counter value after it has been evaluated.

- **`description`** – [in] this is an optional value naming the point in the code marked by the call to this function.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

serialization::binary_filter ***`create_binary_filter`**(char const *binary_filter_type, bool compress, *serialization*::binary_filter *next_filter = nullptr, *error_code* &ec = *throws*)

Create an instance of a binary filter plugin.

> **Note**
>
> As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of hpx::exception.

Parameters

- **`binary_filter_type`** – [in] The type of the binary filter to create
- **`compress`** – [in] The created filter should support compression
- **`next_filter`** – [in] Use this as the filter to dispatch the invocation into.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

hpx/runtime_distributed/applier.hpp

Defined in header hpx/runtime_distributed/applier.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`applier`**

class **`applier`**

#include <applier.hpp> The *applier* class is used to decide whether a particular action has to be issued on a local or a remote resource. If the target component is local a new *thread* will be created, if the target is remote a parcel will be sent.

Public Functions

`applier`(*applier* const&) = delete

`applier`(*applier*&&) = delete

applier &**`operator=`**(*applier* const&) = delete

applier &**`operator=`**(*applier*&&) = delete

applier()

void **init**(*threads*::*threadmanager* &tm)

~applier() = default

void **initialize**(*std*::uint64_t rts)

threads::*threadmanager* &**get_thread_manager**()

Access the *thread-manager* instance associated with this *applier*.

This function returns a reference to the thread manager this applier instance has been created with.

naming::*gid_type* const &**get_raw_locality**(*error_code* &ec = *throws*) const

Allow access to the locality of the locality this applier instance is associated with.

This function returns a reference to the locality this applier instance is associated with.

std::uint32_t **get_locality_id**(*error_code* &ec = *throws*) const

Allow access to the id of the locality this applier instance is associated with.

This function returns a reference to the id of the locality this applier instance is associated with.

bool **get_raw_remote_localities**(*std*::vector<*naming*::*gid_type*> &locality_ids, *components*::*component_type* type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*), *error_code* &ec = *throws*) const

Return list of localities of all remote localities registered with the AGAS service for a specific component type.

This function returns a list of all remote localities (all localities known to AGAS except the local one) supporting the given component type.

Parameters

- **locality_ids** – [out] The reference to a vector of id_types filled by the function.
- **type** – [in] The type of the component which needs to exist on the returned localities.
- **ec** – [in,out] The error code to report failures through.

Returns

The function returns *true* if there is at least one remote locality known to the AGAS service (!prefixes.empty()).

bool **get_remote_localities**(*std*::vector<*hpx*::*id_type*> &locality_ids, *components*::*component_type* type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*), *error_code* &ec = *throws*) const

bool **get_raw_localities**(*std*::vector<*naming*::*gid_type*> &locality_ids, *components*::*component_type* type = to_int(*hpx*::*components*::*component_enum_type*::*invalid*)) const

Return list of locality_ids of all localities registered with the AGAS service for a specific component type.

This function returns a list of all localities (all localities known to AGAS except the local one) supporting the given component type.

Parameters

- **locality_ids** – [out] The reference to a vector of id_types filled by the function.
- **type** – [in] The type of the component which needs to exist on the returned localities.

Returns

The function returns *true* if there is at least one remote locality known to the AGAS service (!prefixes.empty()).

bool **get_localities**(*std*::vector<*hpx*::*id_type*> &locality_ids, *error_code* &ec = *throws*) const

bool **get_localities**(*std*::vector<*hpx*::*id_type*> &locality_ids, *components*::*component_type* type, *error_code* &ec = *throws*) const

inline *naming*::*gid_type* const &**get_runtime_support_raw_gid**() const

By convention the runtime_support has a gid identical to the prefix of the locality the runtime_support is responsible for

inline *hpx*::*id_type* const &**get_runtime_support_gid**() const

By convention the runtime_support has a gid identical to the prefix of the locality the runtime_support is responsible for

Private Members

threads::*threadmanager* ***thread_manager_**

hpx::*id_type* **runtime_support_id_**

hpx::find_locality

Defined in header hpx/runtime.hpp[1025].

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::*id_type* **hpx::find_locality**(*components*::*component_type* type, *error_code* &ec = *throws*)

Return the global id representing an arbitrary locality which supports the given component type.

The function find_locality() can be used to retrieve the global id of an arbitrary locality currently available to this application which supports the creation of instances of the given component type.

See also

hpx::find_here(), hpx::find_all_localities()

Note

Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Note

As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

[1025] http://github.com/TheHPXProject/hpx/blob/bd84353a6b82edd184958b97f4e7f199897b9807/libs/full/include/include/hpx/runtime.hpp

> **Note**
>
> This function will return meaningful results only if called from an HPX-thread. It will return *hpx::invalid_id* otherwise.

Parameters

- `type` – [in] The type of the components for which the function should return any available locality.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Returns

The global id representing an arbitrary locality currently available to this application which supports the creation of instances of the given component type. If no locality supporting the given component type is currently available, this function will return *hpx::invalid_id*.

hpx/runtime_distributed/runtime_support.hpp

Defined in header hpx/runtime_distributed/runtime_support.hpp.

Create the given performance counter instance.

void **remove_from_connection_cache**(*naming*::*gid_type* const &gid, *parcelset*::endpoints_type const &eps)

Remove the given locality from our connection cache.

HPX_DEFINE_COMPONENT_ACTION (runtime_support, terminate_act, terminate_action) HPX_DEFINE_COMPONENT_ACTION(runtime_support

termination detection

terminate_all_action HPX_DEFINE_COMPONENT_ACTION (runtime_support, remove_from_connection_cache) void run()

Start the *runtime_support* component.

void **wait**()

Wait for the *runtime_support* component to notify the calling thread.

This function will be called from the main thread, causing it to block while the HPX functionality is executed. The main thread will block until the shutdown_action is executed, which in turn notifies all waiting threads.

void **stop**(double timeout, *hpx*::*id_type* const &respond_to, bool remove_from_remote_caches, bool force_disconnect)

Notify all waiting (blocking) threads allowing the system to be properly stopped.

> **Note**
>
> This function can be called from any thread.

bool **`remove_locality`**(*hpx*::*id_type* const &locality, *error_code* &ec = *hpx*::*throws*)

Remove the given locality from this locality's runtime support component.

> **Note**
>
> This function must be called locally only; it is not exposed as a component action.

Parameters

- **`locality`** – The locality to be removed.
- **`ec`** – Used to hold error code value originating from the AGAS operations invoked by this function.

void **`stopped`**()

void **`notify_waiting_main`**()

static void **`remove_locality_from_connection_cache`**(*hpx*::*naming*::*gid_type* const &locality, bool skip_current = false)

Broadcast a request to remove the given locality from the connection caches of all remote, non-console localities.

Parameters

- **`locality`** – The locality to remove from the remote connection caches.
- **`skip_current`** – If true, omits the locality identified by *locality* from this broadcast (that locality will not receive a removal request for itself).

static void **remove_locality_from_console_connection_cache**(*hpx*::*naming*::*gid_type* const &locality)

Remove the given locality from the console's connection cache.

Parameters

locality – The locality to remove from the console's connection cache.

supervision

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::supervision::testing::set_register_observer_snapshot_hook

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

void *hpx*::*supervision*::testing::**set_register_observer_snapshot_hook**(*std*::function<void()> hook)

Set the hook invoked after an observer snapshot is captured.

> **Note**
>
> Used for testing purposes only.

Parameters

hook – Hook to invoke. An empty function clears the hook.

hpx::supervision::publish_event

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*

hpx::*future*<publish_result> `hpx::supervision::`**`publish_event`**(*hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0)

Publish a lifecycle event for a target actor on a possibly remote locality.

The function publish_event() asynchronously notifies the supervision manager running on *locality* that *target* has reached the lifecycle state *ev*. Registered observers of *target* are notified as a result.

> **Note**
>
> Publishing is not idempotent: publishing the same event twice creates two distinct records with different timestamps.

> **Note**
>
> Events are immediately visible to observers on the same locality as *target*; remote observers become aware of the event within about 1-2 parcel round-trips to the AGAS authority managing the actor's registration.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) for which the event is published.
- **`ev`** – [in] The lifecycle event to publish for *target*.
- **`epoch`** – [in] The epoch this publication belongs to. Publications are compared against the target's current epoch: publications for a lower epoch are rejected as stale no-ops, publications for a higher epoch reset the target's sequence number and become the new current epoch, and publications for the current epoch are applied normally (subject to terminal-state latching).

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once the event has been recorded by the supervision manager on *locality*, holding `publish_result::applied`, `publish_result::already_terminal` if *target* had already reached a terminal event (`completed` or `failed`) within *epoch*, or `publish_result::stale_epoch` if *epoch* is lower than the target's current epoch.

publish_result `hpx::supervision::`**`publish_event`**(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *hpx*::*throws*)

Publish a lifecycle event for a target actor on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of *publish_event(hpx::id_type const&, hpx::id_type const&, event)*.

Note

Publishing non-terminal events is not idempotent: publishing the same event twice creates two distinct records with different timestamps. `event::completed` and `event::failed` are latched: the first terminal publication for a target wins, and every later terminal publication for that target is a no-op that returns `publish_result::already_terminal`.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) for which the event is published.
- **`ev`** – [in] The lifecycle event to publish for *target*.
- **`epoch`** – [in] The epoch this publication belongs to. See the asynchronous remote overload for the epoch-scoped semantics.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*. As long as *ec* is not pre-initialized to *hpx::throws* this function doesn't throw but returns the result code using the parameter *ec*.

Returns

`publish_result::applied`, `publish_result::already_terminal` if *target* had already reached a terminal event (`completed` or `failed`) within *epoch*, or `publish_result::stale_epoch` if *epoch* is lower than the target's current epoch.

publish_result `hpx::supervision::`**`publish_event`**(*hpx*::*id_type* const &target, *hpx*::*supervision*::event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *throws*)

Publish a lifecycle event for a target actor on the local locality.

This overload publishes *ev* directly through the local supervision manager without going through AGAS or a remote parcel. It is intended to be called from within an actor or action running on the same locality as *target*.

Note

Publishing non-terminal events is not idempotent: publishing the same event twice creates two distinct records with different timestamps. `event::completed` and `event::failed` are latched: the first terminal publication for a target wins, and every later terminal publication for that target is a no-op that returns `publish_result::already_terminal`.

Note

Local observers of *target* are notified synchronously as part of this call.

Parameters

- **`target`** – [in] The actor (or component) for which the event is published. Must be local to the calling locality.

- **`ev`** – [in] The lifecycle event to publish for *target*.
- **`epoch`** – [in] The epoch this publication belongs to. See the asynchronous remote overload for the epoch-scoped semantics.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

`publish_result::applied`, `publish_result::already_terminal` if *target* had already reached a terminal event (`completed` or `failed`) within *epoch*, or `publish_result::stale_epoch` if *epoch* is lower than the target's current epoch.

hpx::*future*<publish_result> `hpx::supervision::`**`publish_event`**(*registry* const &handle, event ev, *std*::uint64_t epoch = 0)

Publish a lifecycle event for the local locality tracked by *handle*.

Convenience overload of hpx::supervision::publish_event(*hpx::id_type* const&, *hpx::id_type* const&, event, std::uint64_t) that resolves both locality and target to *hpx::find_here()* instead of requiring the caller to name them explicitly. Forwards to `hpx::supervision::publish_event( hpx::find_here(), hpx::find_here(), ev, epoch)`.

Parameters

- **`handle`** – [in] The registry (typically returned by *init()*) whose locality the event is published for.
- **`ev`** – [in] The lifecycle event to publish.
- **`epoch`** – [in] The epoch this publication belongs to. Typically obtained from a prior `query_state(hpx::launch::sync, handle).epoch` call. See the raw-id overload for the epoch-scoped semantics.

Returns

A future that becomes ready once the event has been recorded, holding the same *publish_result* values as the raw-id overload.

publish_result `hpx::supervision::`**`publish_event`**(*hpx*::*launch*::sync_policy policy, *registry* const &handle, event ev, *std*::uint64_t epoch = 0, *hpx*::*error_code* &ec = *hpx*::*throws*)

Publish a lifecycle event for the local locality tracked by *handle*, blocking until the operation has completed.

This is the synchronous equivalent of publish_event(registry const&, event, std::uint64_t).

Parameters

- **`policy`** – [in] Tag selecting the blocking overload of *publish_event()*.
- **`handle`** – [in] The registry whose locality the event is published for.
- **`ev`** – [in] The lifecycle event to publish.
- **`epoch`** – [in] The epoch this publication belongs to. See the asynchronous overload.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *handle* does not hold a valid registry client, unless *ec* was pre-initialized to something other than *hpx::throws*.

Returns

The same *publish_result* values as the raw-id overload.

hpx::supervision::query_state

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<lifecycle_state> `hpx::supervision::`**`query_state`**(*hpx*::*id_type* const &locality, *hpx*::*id_type* const &target)

Query the last known lifecycle state of a target actor on a possibly remote locality.

The function query_state() asynchronously retrieves the most recently published lifecycle event for *target*, as observed by the supervision manager running on *locality*.

Note

If *target* is not local to *locality*, the query is forwarded to the actor's home locality, adding about one parcel round-trip of latency.

Note

The returned *lifecycle_state::ec* may carry a staleness error code, indicating that the returned state may be stale if a preceding observer parcel has not yet been delivered.

Note

The *lifecycle_state::event_sequence_number* allows clients to detect gaps, e.g. if an observer callback was skipped due to a network failure.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) whose state is queried.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future holding the last event recorded for *target* (i.e., the most recent value in the runtime's event log), together with its timestamp and sequence number.

lifecycle_state `hpx::supervision::`**`query_state`**(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the last known lifecycle state of a target actor on a possibly remote locality, blocking until the result is available.

This is the synchronous equivalent of query_state(hpx::id_type const&, hpx::id_type const&).

Note

The returned *lifecycle_state::ec* may carry a staleness error code, indicating that the returned state may be stale if a preceding observer parcel has not yet been delivered.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) whose state is queried.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

The last event recorded for *target*, together with its timestamp and sequence number.

lifecycle_state `hpx::supervision::`**`query_state`**(*hpx*::*id_type* const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the last known lifecycle state of a target actor on the local locality.

Parameters

- **`target`** – [in] The actor (or component) whose state is queried. Must be local to the calling locality.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns
The last event recorded locally for *target*, together with its timestamp and sequence number.

hpx::*future*<lifecycle_state> `hpx::supervision::`**`query_state`**`(`*registry* const &handle`)`

Query the last known lifecycle state of the local locality, as tracked by *handle*.

Convenience overload of hpx::supervision::query_state(*hpx::id_type* const&, *hpx::id_type* const&) that resolves both the locality and the target to *hpx::find_here()* instead of requiring the caller to name them explicitly. Forwards to `hpx::supervision::query_state(hpx::find_here(), hpx::find_here())`.

Parameters
`handle` – [in] The registry (typically returned by *init()*) whose locality's state is queried.

Returns
A future holding the last event recorded for the local locality, together with its timestamp, sequence number, and epoch (see *lifecycle_state::epoch* &#8212; in particular, useful for recovering the epoch init() started this locality's lifecycle tracking at, for use with *publish_event()*).

lifecycle_state `hpx::supervision::`**`query_state`**`(`*hpx*::*launch*::sync_policy policy, *registry* const &handle, *hpx*::*error_code* &ec = *hpx*::*throws*`)`

Query the last known lifecycle state of the local locality, as tracked by *handle*, blocking until the result is available.

This is the synchronous equivalent of query_state(registry const&).

Parameters

- **`policy`** – Tag selecting the blocking overload of *query_state()*.
- **`handle`** – [in] The registry whose locality's state is queried.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws
`hpx::exception` – if *handle* does not hold a valid registry client, unless *ec* was pre-initialized to something other than *hpx::throws*.

Returns
The last event recorded for the local locality.

hpx::*future*<lifecycle_state> `hpx::supervision::`**`query_state`**`(`*registry* const &handle, *discovered_peer* const &peer`)`

Query the last known lifecycle state of a discovered peer's locality.

Convenience overload of hpx::supervision::query_state(*hpx::id_type* const&, *hpx::id_type* const&) that resolves both the locality and the target to *peer.locality* instead of requiring the caller to name them explicitly &#8212; mirroring the self-query overload above, but issued against *peer.locality's* own supervision manager instead of the local one. Forwards to `hpx::supervision::query_state(peer.locality, peer.locality)`.

Parameters

- **`handle`** – [in] Unused beyond overload resolution and symmetry with the self-query overload above; *peer* alone carries everything this call needs.
- **`peer`** – [in] The peer (typically returned by *discover_peers()*/ *discover_and_join()*) whose state is queried.

Returns
A future holding the last event recorded for *peer.locality*, as observed by the supervision manager running on *peer.locality*.

lifecycle_state *hpx*::*supervision*::**query_state**(*hpx*::*launch*::sync_policy policy, *registry* const &handle, *discovered_peer* const &peer, *hpx*::*error_code* &ec = *hpx*::*throws*)

Query the last known lifecycle state of a discovered peer's locality, blocking until the result is available.

This is the synchronous equivalent of query_state(registry const&, discovered_peer const&).

Parameters

- `policy` – Tag selecting the blocking overload of *query_state()*.
- `handle` – [in] Unused beyond overload resolution; see the asynchronous overload.
- `peer` – [in] The peer whose state is queried.
- `ec` – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *peer.locality* does not hold a valid registry client, unless *ec* was pre-initialized to something other than *hpx::throws*.

Returns

The last event recorded for *peer.locality*.

hpx::supervision::register_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<*hpx*::*id_type*> *hpx*::*supervision*::**register_observer**(*hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt)

Register a callback to observe lifecycle events published by a target actor running on a possibly remote locality.

Note

If *locality* is the locality *target* is running on, the callback is invoked synchronously from within the publish call (best effort; the callback must not block indefinitely).

Note

If *locality* differs from the locality *target* is running on, the callback is invoked asynchronously via a dedicated parcel, with retry semantics (e.g., 3 attempts over 500 ms before logging failure).

Note

The callback must not throw. An exception thrown from it does not unregister the observer, but it is recorded as *target* having failed (see below).

Note

If *locality* differs from the locality the callback lives on, and sending a notification to the callback fails with `hpx::error::locality_was_disconnected` (e.g. its locality was killed), the observer is unregistered. Such a failure does not change the lifecycle state recorded for *target*. Any other delivery failure, including an exception thrown by the callback itself, is recorded as *target* having failed.

Note

A failed send is told apart from an exception thrown by the callback by the locality the error was raised on. A callback that rethrows a `hpx::error::locality_was_disconnected` error raised on *locality* (e.g. by a call it made back to *locality*) is therefore taken for a failed send, and the observer is unregistered although it is still reachable.

Parameters

- **`locality`** – [in] The locality on which the callback should be registered.
- **`target`** – [in] The actor (or component) to observe.
- **`callback`** – [in] The callback invoked whenever *target* publishes a lifecycle event.
- **`epoch_filter`** – [in] If set, restricts notifications to events published under this epoch; events published under any other epoch are silently skipped for this observer. If `std::nullopt` (the default), the observer is notified regardless of epoch.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future holding the global id of the observer handle. This handle must be passed to unregister_observer() in order to stop receiving notifications.

hpx::*id_type* `hpx::supervision::`**`register_observer`**(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe lifecycle events published by a target actor running on a possibly remote locality, blocking until the registration has completed.

This is the synchronous equivalent of *register_observer*(*hpx::id_type* const&, *hpx::id_type* const&, lifecycle_callback const&).

Parameters

- **`locality`** – [in] The locality on which the callback should be registered.
- **`target`** – [in] The actor (or component) to observe.
- **`callback`** – [in] The callback invoked whenever *target* publishes a lifecycle event.
- **`epoch_filter`** – [in] If set, restricts notifications to events published under this epoch; see the asynchronous overload for details.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_observer() in order to stop receiving notifications.

hpx::*id_type* `hpx::supervision::`**`register_observer`**(*hpx*::*id_type* const &target, lifecycle_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe lifecycle events published by a target actor on the local locality.

Note

The callback is invoked synchronously from within the publish call (best effort; the callback must not block indefinitely) and must not throw. An exception thrown from it does not unregister the observer, but it is recorded as *target* having failed.

Parameters

- **`target`** – [in] The actor (or component) to observe. Must be local to the calling locality.
- **`callback`** – [in] The callback invoked whenever *target* publishes a lifecycle event.
- **`epoch_filter`** – [in] If set, restricts notifications to events published under this epoch; events published under any other epoch are silently skipped for this observer. If `std::nullopt` (the default), the observer is notified regardless of epoch.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *target* does not represent a valid target, unless *ec* was initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_observer() in order to stop receiving notifications.

hpx::supervision::unregister_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<void> `hpx::supervision::`**`unregister_observer`**(*hpx*::*id_type* const &locality, *hpx*::*id_type* const &observer_handle)

Unregister a previously registered observer on a possibly remote locality.

> **Note**
>
> Once the returned future has become ready, no orphaned callbacks fire after unregistration completes.

Parameters

- **`locality`** – [in] The locality on which the observer was registered.
- **`observer_handle`** – [in] The handle returned by a prior call to register_observer(). Only handles returned from that function are accepted; passing a handle obtained from register_activity_observer() (or any foreign handle) is rejected.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid observer handle. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once the observer has been unregistered.

void `hpx::supervision::`**`unregister_observer`**(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, *hpx*::*id_type* const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered observer on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of unregister_observer(hpx::id_type const&, hpx::id_type const&).

Note

No orphaned callbacks fire after unregistration completes.

Parameters

- **`locality`** – [in] The locality on which the observer was registered.
- **`observer_handle`** – [in] The handle returned by a prior call to register_observer(). See the asynchronous overload regarding foreign handles.
- **`ec`** – [in,out] this represents the error status on exit, if this pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid observer handle, unless *ec* was initialized not to *hpx::throws*.

void `hpx::supervision::`**`unregister_observer`**(*hpx*::*id_type* const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered observer on the local locality.

Note

No orphaned callbacks fire after unregistration completes.

Parameters

- **`observer_handle`** – [in] The handle returned by a prior call to register_observer(). Must be local to the calling locality. See the remote overload regarding foreign handles.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *observer_handle* does not represent a valid observer handle, unless *ec* was not pre-initialized to *hpx::throws*.

hpx::supervision::remove_target

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*

- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<void> `hpx::supervision::remove_target`(*hpx*::*id_type* const &locality, *hpx*::*id_type* const &target)

Clear all locally tracked state for a target on a possibly remote locality.

Unlike unregister_observer(), which removes a single previously registered observer handle, remove_target() unconditionally forgets every piece of local state held for *target* - its recorded lifecycle state (see publish_event() / query_state()) and any observers still registered for it (see register_observer()) - regardless of any specific observer handle.

> **Note**
>
> This is intended for callers that know *target* will never be queried or observed again locally (e.g. after a failed registration that seeded some state for it, or once a peer has been evicted), so that local state does not accumulate indefinitely. It is not itself a lifecycle event and does not affect *target's* state on any other locality.

Parameters

- **`locality`** – [in] The locality on which *target's* state is tracked.
- **`target`** – [in] The actor (or component) whose locally tracked state should be removed.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once *target's* state has been removed.

void `hpx::supervision::remove_target`(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Clear all locally tracked state for a target on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of remove_target(hpx::id_type const&, hpx::id_type const&).

Parameters

- **`locality`** – [in] The locality on which *target's* state is tracked.
- **`target`** – [in] The actor (or component) whose locally tracked state should be removed.
- **`ec`** – [in,out] this represents the error status on exit, if this pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was initialized not to *hpx::throws*.

void `hpx::supervision::remove_target`(*hpx*::*id_type* const &target, *hpx*::*error_code* &ec = *hpx*::*throws*)

Clear all locally tracked state for a target on the local locality.

Parameters

- **`target`** – [in] The actor (or component) whose locally tracked state should be removed. Must be local to the calling locality.

- **ec** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*.

hpx::supervision::register_activity_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

hpx::*future*<*hpx*::*id_type*> `hpx::supervision::`**`register_activity_observer`**(*hpx*::*id_type* const &locality, activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt)

Register a callback to observe activity-state transitions of all targets tracked on a possibly remote locality.

Note

For every target tracked on *locality* that is already `activity_state::active` at registration time, the new observer synchronously receives one replay notification (carrying `activity_transition::already_active`) as part of registration, taken under the same lock that serializes activity-state transitions. This guarantees the observer sees exactly one notification for each such target's current activity state: either the replay, or a live transition that raced with registration, but never both and never neither.

Note

If *locality* is the local locality, callbacks (including the registration-time replay) are invoked synchronously from within the call that triggered the transition (best effort; the callback must not block indefinitely).

Note

If *locality* is remote, callbacks are invoked asynchronously via a dedicated parcel, with retry semantics (e.g., 3 attempts over 500 ms before logging failure).

Note

The callback must not throw; exceptions thrown from it are logged and do not affect the observer registration.

Parameters

- **`locality`** – [in] The locality on which the callback should be registered.
- **`callback`** – [in] The callback invoked whenever any target tracked on *locality* transitions between *activity_state::inactive* and *activity_state::active*.
- **`epoch_filter`** – [in] If set, restricts notifications to transitions recorded under this epoch; transitions recorded under any other epoch are silently skipped for this observer. This also applies to the registration-time replay described below. If `std::nullopt` (the default), the observer is notified regardless of epoch.

Throws

`hpx::exception` – if *locality* does not represent a locality. The returned future becomes exceptional if the operation fails.

Returns

A future holding the global id of the observer handle. This handle must be passed to unregister_activity_observer() in order to stop receiving notifications.

hpx::*id_type* `hpx::supervision::`**`register_activity_observer`**(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe activity-state transitions of all targets tracked on a possibly remote locality, blocking until the registration has completed.

This is the synchronous equivalent of *register_activity_observer*(*hpx::id_type* const&, activity_callback const&, std::optional<std::uint64_t>).

Parameters

- **`locality`** – [in] The locality on which the callback should be registered.
- **`callback`** – [in] The callback invoked whenever any target tracked on *locality* transitions between *activity_state::inactive* and *activity_state::active*.
- **`epoch_filter`** – [in] If set, restricts notifications to transitions recorded under this epoch; see the asynchronous overload for details, including how this applies to the registration-time replay.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, unless *ec* was not pre-initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_activity_observer() in order to stop receiving notifications.

hpx::*id_type* `hpx::supervision::`**`register_activity_observer`**(activity_callback const &callback, *std*::optional<*std*::uint64_t> epoch_filter = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Register a callback to observe activity-state transitions of all targets tracked on the local locality.

> **Note**
>
> As for the remote overloads, for every target on the local locality that is already `activity_state::active` at registration time, one `activity_transition::` already_active replay notification is delivered synchronously as part of this call, taken under the same lock that serializes activity-state transitions, so the observer can neither miss nor double-receive any active target's current activity state.

Parameters

- **`callback`** – [in] The callback invoked whenever any target tracked on the local locality transitions between *activity_state::inactive* and *activity_state::active*.
- **`epoch_filter`** – [in] If set, restricts notifications to transitions recorded under this epoch, including the registration-time replay; see the remote overload for details. If `std::nullopt` (the default), the observer is notified regardless of epoch.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if the operation fails, unless *ec* was initialized to *hpx::throws*.

Returns

The global id of the observer handle. This handle must be passed to unregister_activity_observer() in order to stop receiving notifications.

hpx::supervision::unregister_activity_observer

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*

- *hpx::supervision::is_valid_transition*

hpx::*future*<void> `hpx::supervision::unregister_activity_observer`(*hpx*::*id_type* const &locality, *hpx*::*id_type* const &observer_handle)

Unregister a previously registered activity observer on a possibly remote locality.

> **Note**
>
> Once the returned future has become ready, no orphaned callbacks fire after unregistration completes.

Parameters

- **`locality`** – [in] The locality on which the observer was registered.
- **`observer_handle`** – [in] The handle returned by a prior call to register_activity_observer(). Only handles returned from that function are accepted; passing a handle obtained from register_observer() (or any foreign handle) is rejected.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid activity-observer handle. The returned future becomes exceptional if the operation fails.

Returns

A future that becomes ready once the observer has been unregistered.

void `hpx::supervision::unregister_activity_observer`(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, *hpx*::*id_type* const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered activity observer on a possibly remote locality, blocking until the operation has completed.

This is the synchronous equivalent of *unregister_activity_observer*(*hpx::id_type* const&, *hpx::id_type* const&).

> **Note**
>
> No orphaned callbacks fire after unregistration completes.

Parameters

- **`locality`** – [in] The locality on which the observer was registered.
- **`observer_handle`** – [in] The handle returned by a prior call to register_activity_observer(). See the asynchronous overload regarding foreign handles.
- **`ec`** – [in,out] this represents the error status on exit, if this pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *observer_handle* does not represent a valid activity-observer handle, unless *ec* was initialized not to *hpx::throws*.

void `hpx::supervision::unregister_activity_observer`(*hpx*::*id_type* const &observer_handle, *hpx*::*error_code* &ec = *hpx*::*throws*)

Unregister a previously registered activity observer on the local locality.

> **Note**
>
> No orphaned callbacks fire after unregistration completes.

Parameters

- **`observer_handle`** – [in] The handle returned by a prior call to register_activity_observer(). Must be local to the calling locality. See the remote overload regarding foreign handles.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *observer_handle* does not represent a valid activity-observer handle, unless *ec* was not pre-initialized to *hpx::throws*.

hpx::supervision::check_admission

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::await_terminal*
- *hpx::supervision::is_valid_transition*

dispatch_outcome `hpx::supervision::`**`check_admission`**`(`*hpx*::*id_type* const &target, *std*::uint64_t epoch = 0)

Check whether *target* currently admits new dispatch under *epoch*.

Queries the local supervision manager's terminal-latch state for *target* within *epoch*, i.e. the same state maintained by publish_event() and consulted by await_terminal(). Does not publish, mutate state, or notify observers.

> **Note**
>
> This is a pure local read of already-resident latch state, not a query that can fail the way a remote publish_event() call can; it never throws and carries no hpx::error_code out-parameter.

Note

The terminal latch consulted here is populated only by publish_event() calls delivered to *this* locality's supervision manager for *target*. It is not synchronized across localities: a terminal event published to a different locality's manager for the same logical target/epoch is invisible here and does not affect this call's outcome. `register_observer` / `unregister_observer` notifications do not feed this state either. Any locality other than the one hosting *target's* supervision manager that needs to gate its own dispatch decisions on *target's* terminal state must build that cross-locality propagation itself (e.g. registering an observer with the owning locality and re-publishing locally, or routing the admission decision to the owning locality); this API provides no such mechanism.

Parameters

- **`target`** – [in] The actor (or component) to check. Must be local to the calling locality.
- **`epoch`** – [in] The epoch dispatch would occur under.

Returns

`dispatch_outcome::rejected_fenced` if *target* has already latched a terminal event (`completed` or `failed`) under *epoch*, `dispatch_outcome::admitted` otherwise (including when *target* is unknown locally or invalid).

hpx::supervision::await_terminal

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::publish_event*
- *hpx::supervision::query_state*
- *hpx::supervision::register_observer*
- *hpx::supervision::unregister_observer*
- *hpx::supervision::remove_target*
- *hpx::supervision::register_activity_observer*
- *hpx::supervision::unregister_activity_observer*
- *hpx::supervision::check_admission*
- *hpx::supervision::is_valid_transition*

hpx::*future*<lifecycle_state> `hpx::supervision::`**`await_terminal`**(*hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, *std*::uint64_t epoch = 0, *std*::optional<*std*::chrono::steady_clock::duration> timeout = *std*::nullopt)

Asynchronously wait for a target actor on a possibly remote locality to reach a terminal lifecycle event (`completed` or `failed`) within a given epoch.

The function await_terminal() is a one-shot, blocking-free counterpart to register_observer() for the specific case of waiting on the terminal transition: unlike an observer, it does not need to be explicitly unregistered, but it also only ever resolves once, for the exact (*target*, *epoch*) pair passed in.

Note

below for this call only. If `std::nullopt` (the default), *locality's* current default timeout is used instead.

Note

below), and with a *hpx::error::invalid_status* exception if the runtime on *locality* starts shutting down first: all of its pending waiters are invalidated as a pre-shutdown step, and any call made afterwards that would have to wait is rejected the same way.

Note

locality bounds the lifetime of every waiter it registers on behalf of an outstanding call, so dropping the returned future without *target* ever reaching a terminal event under *epoch* does not leak the corresponding waiter entry indefinitely: it is swept and invalidated at or after *timeout* elapses, enforced by a background timer on *locality* independently of any further activity for *target*, so an idle target's waiter is not left to accumulate until some later, unrelated call happens to sweep it. Callers that need a tighter bound than *timeout* should still race the returned future against an external timeout.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) to wait on.
- **`epoch`** – [in] The epoch *target* must reach a terminal event under for the returned future to resolve. If *target's* epoch is later superseded by a higher epoch (see the epoch semantics of *publish_event*) before it reaches a terminal event under *epoch*, the returned future becomes exceptional (see
- **`timeout`** – [in] Overrides the server-enforced timeout described in

Throws

- `below)` – instead of ever resolving with a value.
- `hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target. The returned future becomes exceptional with a *hpx::error::stale_state* exception, naming *target*, *epoch*, and the epoch that superseded it, if *target's* epoch advances past *epoch* before reaching a terminal event under it. It also becomes exceptional with a *hpx::error::future_cancelled* exception if neither of the above happens before *timeout* elapses (see

Returns

A future that becomes ready, holding the *lifecycle_state* recorded for *target*, as soon as *target* reaches a terminal event under *epoch*. If *target* has already reached a terminal event under *epoch* at the time of the call, the returned future is ready immediately.

lifecycle_state `hpx::supervision::`**`await_terminal`**(*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &locality, *hpx*::*id_type* const &target, *std*::uint64_t epoch = 0, *std*::optional<*std*::chrono::steady_clock::duration> timeout = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*)

Wait for a target actor on a possibly remote locality to reach a terminal lifecycle event, blocking until it does.

This is the synchronous equivalent of *await_terminal*(*hpx::id_type* const&, *hpx::id_type* const&, std::uint64_t).

> **Note**
>
> This call blocks until *target* reaches a terminal event, its epoch is superseded, *timeout* elapses, or the runtime on *locality* starts shutting down.

Parameters

- **`locality`** – [in] The locality on which the supervision manager responsible for *target* is running.
- **`target`** – [in] The actor (or component) to wait on.
- **`epoch`** – [in] The epoch *target* must reach a terminal event under. See the asynchronous overload for details.
- **`timeout`** – [in] Overrides the server-enforced timeout described in the asynchronous overload for this call only. If `std::nullopt` (the default), *locality's* current default timeout is used instead.
- **`ec`** – [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

Throws

`hpx::exception` – if *locality* does not represent a locality, or if *target* does not represent a valid target, unless *ec* was not pre-initialized to *hpx::throws*. Also throws (or sets *ec* to) a *hpx::error::stale_state* exception, naming *target*, *epoch*, and the epoch that superseded it, if *target's* epoch advances past *epoch* before reaching a terminal event under it. Also throws (or sets *ec* to) a *hpx::error::future_cancelled* exception if neither of the above happens before *timeout* elapses, or a *hpx::error::invalid_status* exception if the runtime on *locality* starts shutting down first (see the asynchronous overload).

Returns

The *lifecycle_state* recorded for *target* once it reaches a terminal event under *epoch*.

hpx::*future*<lifecycle_state> `hpx::supervision::`**`await_terminal`**(*hpx*::*id_type* const &target, *std*::uint64_t epoch = 0, *std*::optional<*std*::chrono::steady_clock::duration> timeout = *std*::nullopt)

Asynchronously wait for a target actor on the local locality to reach a terminal lifecycle event within a given epoch.

> **Note**
>
> As for the remote overloads, the returned future becomes exceptional with *hpx::error::stale_state* if *epoch* is superseded, with *hpx::error::future_cancelled* if *timeout* elapses first, or with *hpx::error::invalid_status* if the local runtime starts shutting down first.

Parameters

- **`target`** – [in] The actor (or component) to wait on. Must be local to the calling locality.

- **`epoch`** – [in] The epoch *target* must reach a terminal event under. See the remote overload for details.
- **`timeout`** – [in] Overrides the server-enforced timeout described in the asynchronous overload for this call only. If `std::nullopt` (the default), the local locality's default timeout is used instead.

Returns

A future that becomes ready, holding the *lifecycle_state* recorded for *target*, as soon as *target* reaches a terminal event under *epoch*. See the remote overload for how the returned future behaves if *target's* epoch is superseded before reaching a terminal event under *epoch*.

lifecycle_state *`hpx`*`::`*`supervision`*`::`**`await_terminal`**`(`*hpx*::*launch*::sync_policy, *hpx*::*id_type* const &target, *std*::uint64_t epoch = 0, *std*::optional<*std*::chrono::steady_clock::duration> timeout = *std*::nullopt, *hpx*::*error_code* &ec = *hpx*::*throws*`)`

Synchronously wait for a local supervised target to reach a terminal lifecycle state (`completed` or `failed`).

This overload is restricted to targets that are guaranteed to be local to the calling locality. Because no dispatch/AGAS round-trip is required, it is cheaper than the remote `hpx::launch::sync_policy` overload and simply blocks the calling thread on the underlying local future.

Parameters

- **`target`** – The id of the supervised entity to wait on. Must refer to a component that is local to this locality.
- **`epoch`** – The join/generation epoch the caller expects `target` to still be part of. Passing an epoch that no longer matches the target's current epoch may cause the wait to resolve immediately with a mismatch-related error.
- **`timeout`** – Optional upper bound on how long to wait before giving up. If not supplied, uses the local supervision manager's default timeout.
- **`ec`** – Used to report errors instead of throwing an exception. When `target` does not represent a valid id, `hpx::error::bad_parameter` is reported. If the wait is cancelled due to `timeout` elapsing without a terminal state being reached, `hpx::error::future_cancelled` is reported, and if the local runtime starts shutting down first, `hpx::error::invalid_status` is reported.

Throws

`hpx``::`*`exception`* – if `ec` is `hpx::throws` (the default) and an error is encountered; otherwise sets `ec` to reflect the error and returns.

Returns

The terminal `lifecycle_state` observed for `target`, or a default-constructed `lifecycle_state` if an error occurred and `ec` was used to report it.

hpx::supervision::is_valid_transition

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

- *hpx::supervision::check_admission*
- *hpx::supervision::await_terminal*

bool `hpx::supervision::`**`is_valid_transition`**(event from, event to) noexcept

Determine whether transitioning from lifecycle event *from* to lifecycle event *to* is permitted by the supervision lifecycle state machine.

event::completed and *event::failed* are terminal states and have no outgoing transitions. *event::losing_locality* is only reachable from *event::started*, *event::running*, or *event::suspending*, and may only transition to *failed*. A missing prior event is represented as *event::unknown*, from which the only valid transition is to *event::started*.

hpx::supervision::supervision_manager

Defined in header hpx/supervision.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **`supervision_manager`**

hpx/supervision/server/supervision_manager.hpp

Defined in header hpx/supervision/server/supervision_manager.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

void **`unregister_server_instance`**(*error_code* &ec = *throws*) const

publish_result **`publish_event`**(*hpx*::*id_type* const &target, event ev, *std*::uint64_t epoch)

Applies epoch/terminal-latch state-mutation rules, resolves any await_terminal() waiters affected by the transition, and invokes registered per-target lifecycle observers and activity observers for this call.

Parameters

- **`target`** – Target whose supervision state is updated. Must live on this locality.
- **`ev`** – Lifecycle event to apply.
- **`epoch`** – Epoch associated with `ev`.

Returns

The result of applying `ev` to target's state.

lifecycle_state **`query_state`**(*hpx*::*id_type* const &target)

hpx::*id_type* **`register_observer`**(*hpx*::*id_type* const &target, *hpx*::*id_type* const &agent, *std*::uint64_t epoch_filter = static_cast<*std*::uint64_t>(-1))

void **`unregister_observer`**(*hpx*::*id_type* const &observer_handle)

void **`remove_target`**(*hpx*::*id_type* const &target)

Clears all locally tracked state for `target`.

Unlike unregister_observer(), which removes a single previously registered observer handle (and leaves any recorded lifecycle state for its target(s) intact), *remove_target()* unconditionally forgets every piece of local bookkeeping this supervision manager holds for `target` - its recorded lifecycle state and current epoch (see *publish_event()*), and any per-target observers still registered for it (see register_observer()) - regardless of any specific observer handle. Intended for callers that know `target` will never be queried or observed again locally (e.g. after a failed registration that seeded some state for it, or once a peer has been evicted) and want to reclaim that local state instead of letting it accumulate indefinitely.

void **`tidy`**()

Unconditionally clears all locally tracked state.

Snapshots every target currently present in states_ or observers_ under mtx_, releases the lock, then calls *remove_target()* for each one in turn, reusing its existing per-target teardown (waiter invalidation, activity-observer notifications, agent/state cleanup) instead of duplicating that logic here. Targets added concurrently with (or after) the snapshot are left untouched. If states_ and observers_ are empty at snapshot time, this is a no-op: *tidy()* never reports an error and never fires any notification of its own for the "nothing to do" case. Local-only: unlike *remove_target()*, this is not exposed as a remote action.

> **Note**
>
> This is meant for teardown of this locality's supervision state at shutdown. After *tidy()* has been called, remote activity agents are no longer waited for or notified.

void **`cancel_all_waiters`**()

Invalidates every pending await_terminal() waiter.

Drains all of waiters_, regardless of target or epoch, and sets each drained promise to an hpx::error::invalid_status exception. Unlike *tidy()*, this also reaches waiters registered for targets this manager has no recorded state for (e.g. a peer locality polled by a failure detector). Any await_terminal() call made afterwards that would have to register a new waiter fails right away with the same error. Run as a pre-shutdown function, so the continuations attached to the drained futures still execute while the runtime is active, instead of from this object's destructor once it has stopped. Local-only, not exposed as a remote action. Meant for runtime shutdown only, applications must not call it.

hpx::*id_type* **`register_activity_observer`**(*hpx*::*id_type* const &agent, *std*::uint64_t epoch_filter = static_cast<*std*::uint64_t>(-1))

Registers a locality-scoped activity observer.

Replays targets that are already active when registration takes its snapshot.

The snapshot of the target's tracked state and the insertion of the observer into the tracked set happen atomically under `mtx_`, which guarantees the observer receives exactly one notification for the target's current state: either the replay (if already active at registration time) or a live transition that raced with registration, but never both and never neither.

Delivery of that notification (replay or live) happens after `mtx_` is released and is therefore not ordered relative to any other concurrent live notification for the same target; callers must not assume replay is delivered before or after a racing live event.

void **`unregister_activity_observer`**(*hpx*::*id_type* const &observer_handle)

Unregisters an activity observer.

The handle must have been returned by *register_activity_observer()*. As with unregister_observer(), no orphaned callbacks fire after this call completes. `observer_handle` must have been returned by *register_activity_observer()*; a handle returned by register_observer() instead (i.e. found in agents_ rather than activity_observers_) is rejected.

hpx::*future*<lifecycle_state> **`await_terminal`**(*hpx*::*id_type* const &target, *std*::uint64_t epoch = 0, *std*::chrono::steady_clock::duration timeout = (*std*::chrono::steady_clock::duration::max)())

component_storage

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/components/component_storage/migrate_to_storage.hpp

Defined in header hpx/components/component_storage/migrate_to_storage.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Functions

template<typename **Component**>
future<*hpx*::*id_type*> **migrate_to_storage**(*hpx*::*id_type* const &to_migrate, *hpx*::*id_type* const &target_storage)

Migrate the component with the given id to the specified target storage

The function *migrate_to_storage<Component>* will migrate the component referenced by *to_migrate* to the storage facility specified with *target_storage*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The global id of the component to migrate.
- **target_storage** – [in] The id of the storage facility to migrate this object to.

Template Parameters

The – only template argument specifies the component type of the component to migrate to the given storage facility.

Returns

A future representing the global id of the migrated component instance. This should be the same as *migrate_to*.

template<typename **Derived**, typename **Stub**, typename **Data**>
inline *Derived* **migrate_to_storage**(*client_base*<*Derived*, *Stub*, *Data*> const &to_migrate, *hpx*::*components*::component_storage const &target_storage)

Migrate the given component to the specified target storage

The function *migrate_to_storage* will migrate the component referenced by *to_migrate* to the storage facility specified with *target_storage*. It returns a future referring to the migrated component instance.

Parameters

- **to_migrate** – [in] The client side representation of the component to migrate.
- **target_storage** – [in] The id of the storage facility to migrate this object to.

Returns

A client side representation of representing of the migrated component instance. This should be the same as *migrate_to*.

hpx/components/component_storage/migrate_from_storage.hpp

Defined in header hpx/components/component_storage/migrate_from_storage.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

Functions

template<typename **Component**>
future<*hpx*::*id_type*> **migrate_from_storage**(*hpx*::*id_type* const &to_resurrect, *hpx*::*id_type* const &target = *hpx*::invalid_id)

Migrate the component with the given id from the specified target storage (resurrect the object)

The function *migrate_from_storage<Component>* will migrate the component referenced by *to_resurrect* from the storage facility specified where the object is currently stored on. It returns a future referring to the migrated component instance. The component instance is resurrected on the locality specified by *target_locality*.

Parameters

- **to_resurrect** – [in] The global id of the component to migrate.
- **target** – [in] The optional locality to resurrect the object on. By default the object is resurrected on the locality it was located on last.

Template Parameters

The – only template argument specifies the component type of the component to migrate from the given storage facility.

Returns

A future representing the global id of the migrated component instance. This should be the same as *to_resurrect*.

process

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx/components/process/process.hpp

Defined in header hpx/components/process/process.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **components**

namespace **process**

Functions

template<typename ...**Ts**>
child **execute**(*hpx*::*id_type* const &id, *Ts*&&... ts)

HPX_PROCESS_EXPORT child launch_connecting_locality (std::string const &to_launch, std::vector< std::string > const &outer_args={}, std::vector< std::string > const &outer_env={}, std::optional< std::uint64_t > spawn_id=nullopt)

Launch an executable as a new HPX locality that connects to the currently running (bootstrap) locality via TCP.

This function spawns `to_launch` as a child process configured to join the calling HPX runtime as an additional, connecting locality. It forces the TCP parcelport for bootstrapping, forwards AGAS server address/port information from the current runtime's configuration, lets the operating system pick an ephemeral parcel port for the new locality, and blocks the caller until the spawned locality signals that it has finished starting up (via a named latch derived from the executable name and, optionally, `spawn_id`).

> **Note**
>
> The following environment variables are set (overriding any inherited values) before launching:
>
> - `HPX_AGAS_SERVER_ADDRESS` / `HPX_AGAS_SERVER_PORT` ? taken from the current runtime's `hpx.agas.address` / `hpx.agas.port` configuration entries.
> - `HPX_PARCEL_SERVER_ADDRESS` ? same address as the AGAS server.
> - `HPX_PARCEL_SERVER_PORT` ? set to `"0"` so the OS assigns an ephemeral port.
> - `HPX_ON_STARTUP_WAIT_ON_LATCH` ? the startup latch name described above, used to synchronize with the caller.

Parameters

- **`to_launch`** – Path to the executable to launch as the connecting locality.
- **`outer_args`** – Additional command-line arguments appended after the mandatory HPX bootstrap arguments (`--hpx:ignore-batch-env`, `--hpx:ini=hpx.parcel.tcp.priority=1000`, `--hpx:ini=hpx.parcel.bootstrap=tcp`). Defaults to an empty list.

- **`outer_env`** – Additional environment variable entries in `"NAME=value"` form (or just `"NAME"` to set an empty value) that are merged into (and override) the inherited environment before launching the child process. Defaults to an empty list.
- **`spawn_id`** – Optional identifier used to disambiguate the startup latch name when multiple instances of the same executable are launched concurrently. When present, the latch name is `"<exe-stem>/<spawn_id>"`; otherwise it is just `"<exe-stem>"`.

Throws

`hpx::exception` – (or a derived type) if the child process could not be started (`process::throw_on_error()` is used).

Returns

A `child` object representing the launched connecting-locality process, once it has signaled startup completion.

supervision_dispatch

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::supervision::testing::local_snapshot_peers

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::testing::set_failure_detection_poll_timeout_for_testing*
- *hpx::supervision::testing::last_join_locality*
- *hpx::supervision::testing::suspend_heartbeat_for_testing*
- *hpx::supervision::testing::failure_detection_sweep_in_flight_for_testing*
- *hpx::supervision::testing::stop_background_loops*

std::vector<*server*::*peer_snapshot*> `hpx::supervision::testing::`**`local_snapshot_peers`**`()`

Returns a snapshot of this locality's currently-joined, ready peers, as tracked by the local registry. Not part of the public dispatch API - exists so tests can inspect registry state directly.

hpx::supervision::testing::set_failure_detection_poll_timeout_for_testing

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::testing::local_snapshot_peers*
- *hpx::supervision::testing::last_join_locality*
- *hpx::supervision::testing::suspend_heartbeat_for_testing*
- *hpx::supervision::testing::failure_detection_sweep_in_flight_for_testing*
- *hpx::supervision::testing::stop_background_loops*

void *hpx*::*supervision*::testing::**set_failure_detection_poll_timeout_for_testing**(*hpx*::chrono::*steady_duration* const &timeout)

Overrides the timeout failure_detection_loop() passes to *await_terminal()* on each sweep. Must be called before *init()* starts the loop to take effect for that lifecycle; has no effect on a sweep already in flight. Not part of the public dispatch API - exists only to make failure-detection tests deterministic and fast instead of bound by the real 60s default_discovery_timeout.

Parameters

timeout – The new poll timeout.

hpx::supervision::testing::last_join_locality

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::testing::local_snapshot_peers*
- *hpx::supervision::testing::set_failure_detection_poll_timeout_for_testing*
- *hpx::supervision::testing::suspend_heartbeat_for_testing*
- *hpx::supervision::testing::failure_detection_sweep_in_flight_for_testing*
- *hpx::supervision::testing::stop_background_loops*

hpx::*id_type* *hpx*::*supervision*::testing::**last_join_locality**()

Returns the locality most recently returned by join(), regardless of whether the register_observers() call that followed it went on to succeed or fail. Lets tests verify that a failed join() does not leak that locality's local supervision state (see registry::register_observers()'s catch block).

hpx::supervision::testing::suspend_heartbeat_for_testing

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::testing::local_snapshot_peers*
- *hpx::supervision::testing::set_failure_detection_poll_timeout_for_testing*
- *hpx::supervision::testing::last_join_locality*
- *hpx::supervision::testing::failure_detection_sweep_in_flight_for_testing*
- *hpx::supervision::testing::stop_background_loops*

void *hpx*::*supervision*::testing::**suspend_heartbeat_for_testing**()

Stops this locality's own heartbeat_loop() without finalizing the dispatcher, simulating a hard crash (all lifecycle activity ceases, including the periodic event::running pulse) while staying joined in peers' registries. Idempotent; no-op if *init()* was never called or the loop is already stopped. Not part of the public dispatch API - exists only so failure-detection tests can deterministically simulate silence instead of relying on the absence of explicit calls, which no longer implies silence now that heartbeats are mirrored onto observers' local supervision state.

hpx::supervision::testing::failure_detection_sweep_in_flight_for_testing

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::testing::local_snapshot_peers*
- *hpx::supervision::testing::set_failure_detection_poll_timeout_for_testing*
- *hpx::supervision::testing::last_join_locality*
- *hpx::supervision::testing::suspend_heartbeat_for_testing*
- *hpx::supervision::testing::stop_background_loops*

bool `hpx::supervision::testing::`**`failure_detection_sweep_in_flight_for_testing`**`()`

> Reports whether failure_detection_loop() currently has one or more *await_terminal()* calls outstanding against unresponsive peers (i.e. a sweep is mid-flight). Returns false before *init()* is called, between sweeps, and after *finalize()*. Not part of the public dispatch API - exists only so tests can deterministically synchronize on a real in-flight sweep instead of sleeping and hoping the loop got there first.

hpx::supervision::testing::stop_background_loops

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::testing::local_snapshot_peers*
- *hpx::supervision::testing::set_failure_detection_poll_timeout_for_testing*
- *hpx::supervision::testing::last_join_locality*
- *hpx::supervision::testing::suspend_heartbeat_for_testing*
- *hpx::supervision::testing::failure_detection_sweep_in_flight_for_testing*

void `hpx::supervision::testing::`**`stop_background_loops`**`()`

> Stops this locality's failure_detection_loop() and heartbeat_loop() background tasks (joining both) without otherwise finalizing the dispatcher: unlike *finalize()*, this never publishes event::completed, never unregisters the registry symbol name, and never resets the lifecycle state back to uninitialized, so the sentinel's last published event stays stale and peers' failure_detection_loop() still eventually times out and observes target_fenced/rejected_fenced against this locality. Lets a caller depart the HPX runtime cleanly (e.g. via *hpx::disconnect()*) afterwards without leaving either background hpx::async task still running - simulating a worker that dies mid-epoch without corrupting AGAS or hanging runtime shutdown, as opposed to a true crash (no call at all) or a fully graceful departure (*finalize()*). Idempotent; no-op if *init()* was never called or the loops are already stopped. Not part of the public dispatch API - exists only for examples/tests that need to simulate this exact scenario deterministically.

hpx::supervision::init

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::finalize*
- *hpx::supervision::is_initialized*

hpx::*shared_future*<*registry*> `hpx::supervision::init`(*hpx*::chrono::*steady_duration* const &discovery_timeout = *default_discovery_timeout*)

Performs one-shot, idempotent initialization of the supervision-dispatch runtime for this locality. On the first successful call, this function atomically transitions the internal lifecycle state from *uninitialized* to *initializing*, after incrementing the internal epoch, then owns the entire startup sequence: it creates a local *registry* for hpx::find_here(), publishes *event::started* for this locality *before* the registry's symbol name is registered (so that no peer can discover and join a not-yet-started locality), registers that symbol name, and finally performs a single *discover_and_join()* pass to join every currently reachable peer registry. On success the state transitions to *active*; if any step throws, all partial state is rolled back and the lifecycle reverts to *uninitialized* so that a subsequent call can retry from scratch.

Calling init() while already *active* is a no-op that resolves immediately without repeating any side effect. Calling it while another call is still *initializing* attaches the caller to the in-flight operation's outcome rather than racing it, so concurrent callers never create more than one registry. Calling it while *finalizing* is in progress is rejected; callers should wait for *finalize()* to complete before re-initializing.

> **Note**
>
> This function has no effect on any state that has not yet been created by a successful call - in particular, no symbol name is ever registered and no event is ever published unless this function (or a concurrent call it is attached to) actually runs the initialization sequence.

Parameters

`discovery_timeout` – The maximum duration to wait, across all discovery candidates combined, for peer registry symbol names to resolve during the *discover_and_join()* step (see *discover_peers()*).

Returns

A shared future that becomes ready, holding the *registry* owned by this *init()* cycle, once the supervision runtime has reached the *active* state, or that becomes exceptional if initialization fails.

registry `hpx::supervision::init`(*hpx*::*launch*::sync_policy policy, *hpx*::chrono::*steady_duration* const &discovery_timeout = *default_discovery_timeout*)

Performs one-shot, idempotent initialization of the supervision-dispatch runtime for this locality, blocking the calling thread until the operation completes. This is the synchronous counterpart of init(hpx::chrono::steady_duration const&): it carries out the exact same lifecycle transition and startup sequence (registry creation, *event::started* publication, symbol name registration, and a single *discover_and_join()* pass), but waits for the resulting future to become ready (or exceptional) before returning, rather than handing the future back to the caller.

Note

As with the asynchronous overload, no symbol name is registered and no event is published unless this call (or a concurrent call it attaches to) actually performs the initialization sequence.

Parameters

- `policy` – Tag selecting the blocking overload of init().
- `discovery_timeout` – The maximum duration to wait, across all discovery candidates combined, for peer registry symbol names to resolve during the *discover_and_join()* step (see *discover_peers()*).

Throws

`hpx::exception` – if initialization could not complete (e.g. due to a concurrent *finalize()* still in progress). Calling this while already *active* is a no-op that returns immediately.

Returns

The *registry* owned by this *init()* cycle.

hpx::supervision::finalize

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::init*
- *hpx::supervision::is_initialized*

void `hpx::supervision::`**`finalize`**`()`

Performs one-shot, idempotent teardown of the supervision-dispatch runtime previously started by *init()*. On the first call observing the *active* state, this function atomically transitions the lifecycle to *finalizing*, publishes *event::completed* for the local locality at the current epoch, unregisters the registry's symbol name, and then releases ownership of the registry (relying on *client_base's* default lifetime management to destroy it once no other references remain) before resetting the lifecycle back to *uninitialized*, allowing a subsequent *init()* call to re-arm the runtime from scratch.

Calling finalize() when the runtime is *uninitialized*, still *initializing*, or already *finalizing* is a documented no-op: it resolves immediately without publishing any event, unregistering any symbol name, or otherwise touching component state.

Note

Because finalize() is a no-op unless the runtime is currently *active*, it is always safe to call speculatively, e.g. during shutdown, without first checking *is_initialized()*.

hpx::supervision::is_initialized

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::init*
- *hpx::supervision::finalize*

bool *hpx*::*supervision*::**is_initialized**() noexcept

Returns whether the supervision-dispatch runtime for this locality is currently *active*, i.e. has completed *init()* and has not yet been torn down by *finalize()*.

> **Note**
>
> This function never blocks and performs a single atomic load; it is safe to call from any thread, including while *init()* or *finalize()* is concurrently in flight.

Returns

true if the lifecycle state is *active*, *false* if it is *uninitialized*, *initializing*, or *finalizing*.

hpx::supervision::registry

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

class **registry** : public *hpx*::*components*::*client_base*<*registry*, *server*::*registry*>

A registry is a lightweight, self-supervising handle for pairing with peer localities. It mirrors a peer's lifecycle state locally via join(), and can itself be discovered by name in AGAS like other supervision_dispatch components.

hpx::supervision::dispatch_work

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

hpx::supervision::invoke_fenced_action

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::dispatch_work*

template<typename **`Action`**, typename **`IdType`**, typename **`Epoch`**, typename ...**`Ts`**>
decltype(auto) `hpx::supervision::`**`invoke_fenced_action`**(*Action* act, *IdType* target, *Epoch* const epoch, *Ts*... ts)

Remote dispatch point that performs the authoritative admission re-check and invokes the wrapped action.

This is the function body that actually runs as the action on the *destination* locality (the target’s own locality, reached via hpx::colocated in dispatch_work()). It is invoked by fenced_action once the action has been dispatched.

The admission check performed here runs on the same locality/thread that owns the target’s *supervision_manager* state, so there is no suspension point between this check and the actual invocation below. This is what closes the client-side/dispatch race: even if the client’s own (non-authoritative) *check_admission()* in dispatch_work() returned `admitted`, the target may have latched a terminal event for this epoch in the meantime, and this re-check will catch it.

This re-check is authoritative only because a joining registry (see components/supervision_dispatch/src/server/registry_server.cpp) dual-publishes lifecycle mirrors for a joined peer onto that peer's own locality, in addition to the joining registry's local copy: `target` must resolve to that same peer locality for this guarantee to hold. Dispatching `target` against an unrelated third locality - one that never received the dual-published mirror for this target - remains out of contract; the re-check performed there consults a *supervision_manager* state that was never seeded for `target` and so cannot detect fencing.

Template Parameters

- **`Action`** – The wrapped HPX action type to invoke on admission.
- **`IdType`** – Type of the target identifier forwarded to `act` (this type is always *`hpx::id_type`*).
- **`Epoch`** – Type of the fencing epoch value (this type is always `std::uint64_t`).
- **`Ts`** – Types of the additional arguments forwarded to `act`.

Parameters

- **`act`** – The action instance to invoke once admission succeeds.
- **`target`** – Identifier of the component instance being dispatched to; forwarded to `act` (the epoch is fencing metadata only and is not part of `act's` argument list).
- **`epoch`** – The fencing epoch to check admission for.
- **`ts`** – Additional arguments forwarded to `act`.

Throws

`hpx``::`*`exception`* – with hpx::error::target_fenced if the target has latched a terminal event for `epoch` since the client's own admission check, in which case the wrapped action is not invoked.

Returns

The result of invoking `act`, obtained via hpx::sync (run directly/locally, without an extra parcel hop, since this function already executes on the target's locality).

hpx::supervision::discover_peers

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::fan_out_join*
- *hpx::supervision::discover_and_join*

std::vector<*discovered_peer*> `hpx::supervision::`**`discover_peers`**(chrono::*steady_duration* const &timeout = *default_discovery_timeout*)

Performs a one-time discovery pull for supervision_dispatch peers: concurrently resolves the pinned registry name (see register_name()) of every remote locality (*hpx::find_remote_localities()*, which already excludes this locality), bounded by a single wait for *timeout* across all candidates.

Because constructing a registry client from a symbolic name (see client_base's symbolic-name constructor) waits/resolves once the symbol is bound rather than failing fast on one that is not (yet) registered, localities that never called register_name() (e.g. because they have not run init_supervision() yet) would otherwise hang this call indefinitely. Instead, once *timeout* elapses, only the candidates whose registry client was resolved by then (checked via the non-blocking is_ready()) are returned; every other candidate is simply excluded as not currently participating in supervision - *discover_peers()* itself never fails or throws on their account.

Parameters

`timeout` – The maximum duration to wait, across all candidates combined, for their registry names to resolve.

Returns

The peers whose registry client was resolved within *timeout*, as discovered_peer values carrying the *hpx::id_type* locality it is pinned to.

hpx::supervision::fan_out_join

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::discover_peers*
- *hpx::supervision::discover_and_join*

std::vector<*discovered_peer*> `hpx::supervision::`**`fan_out_join`**(*registry* const &local_registry, *std*::vector<*discovered_peer*> const &peers, chrono::*steady_duration* const &timeout = *default_discovery_timeout*)

Reactively fans out join() calls from *local_registry* to every peer in *peers* (typically the result of a prior *discover_peers()* call): for each entry, this calls `local_registry.join(peer.locality)`.

This reuses registry::join()'s existing reservation/idempotency machinery unchanged (see server::registry::reserve_ownership()) rather than duplicating any of it, so calling *fan_out_join()* more than once with (partially) overlapping peer lists - or racing with an inbound join() call from one of those same peers, e.g. because that peer is concurrently running its own *fan_out_join()* against this locality - is safe and never creates more than one registry entry per peer locality.

fan_out_join() itself is reactive only: it performs exactly one round of join() calls for the given *peers* and starts no background/polling activity of its own.

Parameters

- `local_registry` – The registry to join every peer in *peers* to.
- `peers` – The peers to join, typically returned by a prior *discover_peers()* call.
- `timeout` – The maximum duration to wait, across all peers combined, for their join() calls to settle. Peers whose join() has not settled (or failed) within this bound are silently dropped from the result, rather than hanging or throwing.

Returns

The discovered_peer values (locality + join_epoch) for peers whose join() calls settled successfully within *timeout*, in the same relative order as *peers* (with unsuccessful/ timed-out peers omitted, rather than left as gaps). Each returned discovered_peer::join_epoch is populated from the corresponding join() call, so callers can dispatch against `{peer.locality, peer.join_epoch}` directly, without needing a separate join() call to obtain it.

hpx::supervision::discover_and_join

Defined in header hpx/supervision_dispatch.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

See also:

- *hpx::supervision::discover_peers*
- *hpx::supervision::fan_out_join*

std::vector<*discovered_peer*> `hpx::supervision::`**`discover_and_join`**(*registry* const &local_registry, chrono::*steady_duration* const &timeout = *default_discovery_timeout*)

Composes a single reactive discovery-and-join pass for supervision_dispatch peers: performs exactly one *discover_peers()* pull to resolve the pinned registry name of every remote locality (*hpx::find_remote_localities()* already excludes this locality, so no separate self-exclusion is needed here), then fans the resulting peer list out to *local_registry* via a single *fan_out_join()* pass.

discover_and_join() introduces no state, polling thread, timer, or repeated broadcast of its own - it is a pure composition of *discover_peers()* and *fan_out_join()*, each of which is itself bounded to a single round of resolution/join calls. Because *fan_out_join()* reuses registry::join()'s existing reservation/idempotency machinery unchanged (see server::registry::reserve_ownership()), calling *discover_and_join()* more than once - whether to pick up newly started peers or purely by accident - is safe and never creates more than one registry entry per peer locality; repeated invocations simply return the (stable) join epochs already owned for peers that were previously joined.

Parameters

- **`local_registry`** – The registry to join every discovered peer to.
- **`timeout`** – The maximum duration to wait, across all discovery candidates combined, for their registry name to resolve (see *discover_peers()*).

Returns

The discovered_peer value that *local_registry* created (or already had) for each peer discovered and successfully joined within *timeout*, in the same relative order as returned by *discover_peers()*.

hpx/supervision_dispatch/server/registry.hpp

Defined in header hpx/supervision_dispatch/server/registry.hpp.

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **`hpx`**

namespace **`supervision`**

Fenced action dispatch for the supervision subsystem.

This header provides the machinery to dispatch an HPX action to a target component while enforcing supervision "fencing" semantics: once a target has latched a terminal event for a given epoch, no further actions for that epoch may execute against it. Dispatch performs a cheap, non-authoritative admission check on the caller's locality and an authoritative re-check on the target's own locality (via hpx::colocated), immediately before invoking the wrapped action, closing the race between admission and invocation.

Types and functions implementing HPX's supervision and fenced dispatch facilities.

Functions

inline bool **`operator==`**(*joined_peer* const &lhs, *joined_peer* const &rhs) noexcept

inline bool **`operator!=`**(*joined_peer* const &lhs, *joined_peer* const &rhs) noexcept

std::ostream &**`operator<<`**(*std*::ostream &strm, *joined_peer* const &peer)

struct **`joined_peer`**

#include <registry.hpp> Pairs the two values a caller obtains from a successful `registry::join()` and needs to perform a fenced dispatch.

See also

dispatch_work()

See also

server::registry::join()

Public Members

hpx::*id_type* **`target`**

The real, colocatable destination for the wrapped action.

The peer's locality id (i.e. `peer_locality`, the value originally passed into `registry::join()`). Forwarded to `hpx::colocated()` and used as the destination of `hpx::sync(act, target, ts...)` inside `dispatch_work()`.

std::uint64_t **`join_epoch`** = 0

The epoch at which this peer was joined.

Recorded by `registry::join()` and used to identify which registry entry a later `registry::leave()` call refers to - so that a racing re-join of the same peer locality (which mints a fresh `join_epoch` of its own) cannot be mistaken for the join this `joined_peer` was returned from.

namespace **`server`**

struct **`peer_snapshot`**

#include <registry.hpp> Plain-data view of a single joined peer, safe to hand out to callers outside the registry (unlike peer_entry, does not expose the ready/evict_pending bookkeeping used internally to coordinate concurrent join()/evict_peer() calls).

Public Members

hpx::*id_type* **`peer_locality`**

The peer locality this entry was joined against.

std::uint64_t **`join_epoch`**

The epoch at which `peer_locality` was joined.

std::uint64_t **`generation`**

Identifies this particular registry entry. A peer that is left and joined again gets a new one, even if its `join_epoch` is the same. See *registry::evict_fenced()*.

class **`registry`** : public *hpx*::*components*::*component_base*<*registry*>

Public Functions

`registry`()

joined_peer **`join`**(*hpx*::*id_type* const &peer_locality)

Joins a peer locality and creates or reuses its local supervision state.

Parameters

`peer_locality` – The peer locality to observe.

std::vector<*peer_snapshot*> **`snapshot_peers`**() const

Returns a point-in-time snapshot of all fully joined, non-evicting peers.

Intended for a future failure-detection poller (or other local consumers) that needs a stable, lock-safe list of peers to iterate over without reaching into `peers_` directly. Entries mid-join (ready == false) or already scheduled for eviction (evict_pending == true) are excluded, so a poller never observes a half-registered or torn-down peer.

Returns

A snapshot of every peer entry with `ready` == true and `evict_pending` == false at the time of the call.

void **`leave`**(*hpx*::*id_type* const &peer_locality, *std*::uint64_t join_epoch)

Removes a previously joined peer.

Parameters

- **`peer_locality`** – The peer locality to leave.
- **`join_epoch`** – Must match the join epoch currently recorded for `peer_locality` (i.e. the epoch returned by the corresponding *join()*). If `peer_locality` has since been re-joined (fresh epoch) or already evicted, this call is a no-op.

void **`evict_fenced`**(*hpx*::*id_type* const &peer_locality, *std*::uint64_t generation)

Removes a joined peer whose local supervision state has latched a terminal event without the peer itself reporting one, i.e. one that failure detection fenced. The terminal state is left in place as a tombstone (see *cleanup_peer()*), so the peer stays fenced.

Parameters

- **`peer_locality`** – The peer locality to remove.
- **`generation`** – The *peer_snapshot::generation* of the entry to remove. If `peer_locality` has since been evicted, or left and joined again (which creates a new entry, even if its join epoch is the same), or its local supervision state is no longer terminal, this call is a no-op.

Protected Functions

std::tuple<*hpx*::*id_type*, *std*::uint64_t, bool> **reserve_ownership**(*hpx*::*id_type* const &peer_locality)

std::pair<*hpx*::*id_type*, *hpx*::*id_type*> **register_observers**(*hpx*::*id_type* const &peer_locality, *std*::uint64_t join_epoch)

void **evict_peer**(*hpx*::*id_type* const &peer_locality, *std*::uint64_t join_epoch, *hpx*::*id_type* keep_alive, bool preserve_terminal_state)

Protected Static Functions

static void **cleanup_peer**(*hpx*::*id_type* const &peer_locality, *hpx*::*id_type* const &lifecycle_observer, *hpx*::*id_type* const &activity_observer, bool preserve_terminal_state)

Unregisters a peer's observers and, unless `preserve_terminal_state` is set, removes its locally tracked supervision state.

Performs the actual peer teardown deferred by evict_peer(): unregisters `lifecycle_observer` and `activity_observer` on `peer_locality`, and removes `peer_locality's` locally tracked supervision state unless `preserve_terminal_state` is true, in which case that state - which was last set to the peer's terminal event by register_observers()'s lifecycle callback - is left in place as a tombstone rather than reset to "unknown". This lets any admission check still in flight against `peer_locality` (e.g. check_admission()) keep observing the fenced/terminal outcome after eviction has run, instead of racing against it. A subsequent *join()* re-seeding this locality with a fresh epoch naturally overwrites the tombstone. Kept separate from evict_peer() because evict_peer() only posts this work as a task (via hpx::post()) rather than performing it inline.

Parameters

- **`peer_locality`** – The locality that owns the observers, and whose local supervision state is removed.
- **`lifecycle_observer`** – The lifecycle observer id to unregister.
- **`activity_observer`** – The activity observer id to unregister.
- **`preserve_terminal_state`** – If true, leave peer_locality's local supervision state in place instead of removing it.

Private Members

mutable *hpx*::*spinlock* **mtx_**

hpx::*lcos*::*local*::detail::condition_variable **cond_**

std::map<*hpx*::*id_type*, *peer_entry*> **peers_**

std::uint64_t **next_generation_** = 0 struct **peer_entry**

Internal bookkeeping for a single joined (or joining) peer.

Not exposed outside the registry; see *peer_snapshot* for the plain-data subset safe to hand to external callers.

Public Functions

inline explicit **peer_entry**(*hpx*::*id_type* const &peer_locality)

Public Members

hpx::*id_type* const **peer_locality**

The locality that owns this peer's. Surfaced read-only via *peer_snapshot::peer_locality*.

hpx::*id_type* **lifecycle_observer**

The observer id registered on peer_locality to receive this peer's terminal lifecycle notification (drives evict_peer() via hpx::post()).

hpx::*id_type* **activity_observer**

The observer id registered on peer_locality to receive this peer's activity notifications (used to keep peer_locality's local state current between terminal events).

std::uint64_t **join_epoch** = 0

The epoch at which this peer was joined, recorded by *join()* and used by evict_peer() (instead of shadow) to identify and used by evict_peer() to identify which entry a deferred eviction refers to.

bool **ready** = false

False while a *join()* call has reserved ownership of this peer's locality (i.e. is in the process of performing the remote observer registrations) but has not yet filled in the rest of the entry. Concurrent *join()* calls for the same peer wait on cond_ instead of racing to register duplicate observers.

bool **evict_pending** = false

True once a terminal notification has been observed for this peer but eviction has not yet completed (deferred via hpx::post() to evict_peer()). Ensures a terminal notification racing ahead of *join()* completion is deferred instead of dropped, and lets *snapshot_peers()* exclude a peer that is already tearing down.

std::uint64_t **generation** = 0

Unique for each entry this registry creates, surfaced via *peer_snapshot::generation*. Lets *evict_fenced()* tell the entry it was asked to remove apart from a later one for the same peer locality.

bool **`evict_preserve_terminal_state`** = false

The preserve_terminal_state argument evict_peer() was called with when it set evict_pending above, remembered so that *join()*'s deferred *cleanup_peer()* call (once the join in progress completes) preserves or drops peer_locality's local supervision state consistently with what the racing terminal notification requested.

2.10 Contributing to *HPX*

HPX development happens on Github. The following sections are a collection of useful information related to *HPX* development.

2.10.1 Contributing to *HPX*

The main source of information to understand the process of how to contribute to HPX can be found in this document[1026]. This is a living document that is constantly updated with relevant information.

2.10.2 *HPX* governance model

The *HPX* project is a meritocratic, consensus-based community project. Anyone with an interest in the project can join the community, contribute to the project design and participate in the decision making process. This document[1027] describes how that participation takes place and how to set about earning merit within the project community.

2.10.3 Release procedure for *HPX*

Below is a step by step procedure for making an *HPX* release. We aim to produce two releases per year: one in March-April, and one in September-October.

This is a living document and may not be totally current or accurate. It is an attempt to capture current practices in making an *HPX* release. Please update it as appropriate.

One way to use this procedure is to print a copy and check off the lines as they are completed to avoid confusion.

1. Notify developers that a release is imminent.
2. For minor and major releases: create and check out a new branch at an appropriate point on `master` with the name `release-major.minor.X`. `major` and `minor` should be the major and minor versions of the release. For patch releases: check out the corresponding `release-major.minor.X` branch.
3. Write release notes in `docs/sphinx/releases/whats_new_$VERSION.rst`. Keep adding merged PRs and closed issues to this until just before the release is made. From a checkout with complete history, run `tools/generate_issue_pr_list.sh BASE_REF RELEASE_REF` to generate the lists. Choose and record the previous release or maintenance revision as `BASE_REF` and pin `RELEASE_REF` to the release commit (defaults to `HEAD`). The generator includes merged PRs present only in the release history, even outside the milestone. Review cherry-picked or rebased PRs separately and record their landed commits. Closed milestone issues are listed independently and are not evidence that a feature was implemented. Use `--limit` to print the newest 50 entries after reconciliation. Add the new release notes to the table of contents in `docs/sphinx/releases.rst`.
4. Build the docs, and proof-read them. Update any documentation that may have changed, and correct any typos. Pay special attention to:

[1026] https://github.com/TheHPXProject/hpx/blob/master/.github/CONTRIBUTING.md

[1027] http://hpx.dev/documents/governance/

   - `$HPX_SOURCE/README.rst`
      - Update grant information
   - `docs/sphinx/releases/whats_new_$VERSION.rst`
   - `docs/sphinx/about_hpx/people.rst`
      - Update collaborators
      - Update grant information

5. Make sure `HPX_VERSION_MAJOR/MINOR/SUBMINOR` in `CMakeLists.txt` contain the correct values. Change them if needed.
6. Change version references in CITATION.cff. There are two occurrences. Change year in the copyright file under `/libs/core/version/src/version.cpp`.
7. This step does not apply to patch releases. Remove features which have been deprecated for at least 2 releases. This involves removing build options which enable those features from the main CMakeLists.txt and also deleting all related code and tests from the main source tree.

   The general deprecation policy involves a three-step process we have to go through in order to introduce a breaking change:

   a. First release cycle: add a build option that allows for explicitly disabling any old (now deprecated) code.
   b. Second release cycle: turn this build option OFF by default.
   c. Third release cycle: completely remove the old code.

   The main CMakeLists.txt contains a comment indicating for which version the breaking change was introduced first. In the case of deprecated features which don't have a replacement yet, we keep them around in case (like Vc for example).
8. Update the minimum required versions if necessary (compilers, dependencies, etc.) in `prerequisites.rst`. Update latest tested versions.
9. Verify that the Jenkins setups for the release branch on Rostam are running and do not display any errors.
10. Repeat the following steps until satisfied with the release.
    1. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to `-rcN`, where `N` is the current iteration of this step. Start with `-rc1`.
    2. Create a pre-release on GitHub using the script `tools/roll_release.sh`. This script automatically tag with the corresponding release number. The script requires that you have the STE||AR Group signing key.
    3. This step is not necessary for patch releases. Notify `hpx-users@stellar-group.org` of the availability of the release candidate. Ask users to test the candidate by checking out the release candidate tag.
    4. Allow at least a week for testing of the release candidate.
       - Use `git merge` when possible, and fall back to `git cherry-pick` when needed. For patch releases `git cherry-pick` is most likely your only choice if there have been significant unrelated changes on master since the previous release.
       - Go back to the first step when enough patches have been added.
       - If there are no more patches, continue to make the final release.
11. Update any occurrences of the latest stable release to refer to the version about to be released. For example, `quickstart.rst` contains instructions to check out the latest stable tag. Make sure that refers to the new version.
12. Add a new entry to the RPM changelog (`cmake/packaging/rpm/Changelog.txt`) with the new version number and a link to the corresponding changelog.

13. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to an empty string.
14. Add the release date to the caption of the current "What's New" section in the docs, and change the value of `HPX_VERSION_DATE` in `CMakeLists.txt`.
15. Create a release on GitHub using the script `tools/roll_release.sh`. This script automatically tag the with the corresponding release number. The script requires that you have the STE||AR Group signing key.
16. Update the website (hpx.dev[1028]). You can login on wordpress through *this page <https://hpx.dev/wp-login.php>*. You can update the pages with the following:
    - Update links on the downloads page. Link to the release on GitHub.
    - Documentation links on the docs page (link to generated documentation on GitHub Pages). Follow the style of previous releases.
    - A new blog post announcing the release, which links to downloads and the "What's New" section in the documentation (see previous releases for examples).
17. Merge release branch into master.
18. Post-release cleanup. Create a new pull request against master with the following changes:
    1. Modify the release procedure if necessary.
    2. Change `HPX_VERSION_TAG` in `CMakeLists.txt` back to `-trunk`.
    3. Increment `HPX_VERSION_MINOR` in `CMakeLists.txt`.
19. Update Vcpkg (`https://github.com/Microsoft/vcpkg`) to pull from latest release.
    - Update version number in CONTROL
    - Update tag and SHA512 to that of the new release
20. Update spack (`https://github.com/spack/spack`) with the latest HPX package.
    - Update version number in `hpx/package.py` and SHA256 to that of the new release
21. Announce the release on hpx-users@stellar-group.org, stellar@cct.lsu.edu, allcct@cct.lsu.edu, faculty@csc.lsu.edu, faculty@ece.lsu.edu, the *HPX* Slack channel, the STEllAR-GROUP Discord channel, our list of external collaborators, isocpp.org, reddit.com, HPC Wire, Inside HPC, Heise Online, and a CCT press release.
22. Beer and pizza.

2.10.4 Testing *HPX*

To ensure correctness of *HPX*, we ship a large variety of unit and regression tests. The tests are driven by the CTest[1029] tool and are executed automatically on each commit to the *HPX* Github[1030] repository. In addition, it is encouraged to run the test suite manually to ensure proper operation on your target system. If a test fails for your platform, we highly recommend submitting an issue on our *HPX* Issues[1031] tracker with detailed information about the target system.

[1028] https://hpx.dev

[1029] https://gitlab.kitware.com/cmake/community/wikis/doc/ctest/Testing-With-CTest

[1030] https://github.com/TheHPXProject/hpx/

[1031] https://github.com/TheHPXProject/hpx/issues

Running tests manually

Running the tests manually is as easy as typing `make tests && make test`. This will build all tests and run them once the tests are built successfully. After the tests have been built, you can invoke separate tests with the help of the `ctest` command. You can list all available test targets using `make help | grep tests`. Please see the CTest Documentation[1032] for further details.

Running performance tests

For each pull request, Jenkins runs the performance tests on Rostam (see `.jenkins/lsu-perftests`) and posts a comparison with the reference results on the pull request. To run a performance test yourself, configure *HPX* with `-DHPX_WITH_TESTS_RUN_BENCHMARKS=ON` (and `-DHPX_WITH_NANOBENCH=ON`, as the CI does) and build the target `<name>_perftest`, e.g. `benchmark_merge_perftest`. It runs the benchmark 30 times (or as often as the `N_EXECUTIONS` argument of `add_hpx_performance_report_test` says) and writes the results to `tools/perftests_ci/results/<name>.json` in the build directory. Then build the target `perftests_plot`, which compares all results found there with the reference results, and writes the measurements and their plots to `tools/perftests_ci/index.html`.

Adding new performance tests

To add a new performance test, wrap the portion of code to benchmark with `hpx::util::perftests_report`, passing the test name, the executor name, the number of repetitions and the function to time (can be a lambda). Add the command line options of this facility with `hpx::util::perftests_cfg` in `main`, call `hpx::util::perftests_init(vm, "<name>")` at the beginning of `hpx_main`, using the name of the test, and call `hpx::util::perftests_print_times` at the end to print the results in the json format used for the comparison. See `future_overhead_report.cpp` for an example.

To add the test to the CI report, register it with `add_hpx_performance_report_test` if `HPX_WITH_TESTS_RUN_BENCHMARKS` is enabled (see `libs/core/algorithms/tests/performance/CMakeLists.txt`); the CI builds and runs all registered performance tests. Finally, add the reference results. The timings differ between the nodes the CI may run on, so each node has its own reference results in `tools/perftests_ci/perftest/references/<node>.tar.gz`, and the comparison uses the ones of the node the benchmarks ran on. If a benchmark has no reference on that node, because it is new or its measurements changed, the CI makes new references of all benchmarks of the node from the run, so that they are measured together, and always uploads them, packed, to `TheHPXProject/hpx-perftest-images` (`pr/<pull request>/<build>/references` or `branch/<branch>/<build>/references`); the report links to them. Copy the archive to `tools/perftests_ci/perftest/references` to use them. To update a single reference by hand, build the `<name>_perftest` target on that node, copy `tools/perftests_ci/results/<name>.json` from the build directory to the unpacked reference results of the node, and pack them again with `tools/perftests_ci/pack_references.sh` (see the comment at the top of the script). The CI comments on a pull request only about measurements that got more than 5% faster or slower; the pull request comment `retest lsu perf full` starts a run that reports all measurements. Every CI run also keeps all of its results packed as references of its node (`perftests-reports/references/<node>.tar.gz` in the Jenkins artifacts).

The performance tests also run for the commits of the master branch, always on the same node (`configuration_slurm_history_node` in `.jenkins/lsu-perftests/slurm-constraint-perftests.sh`, a node the build matrix doesn't use) and always reporting all measurements. Each of these runs is added to the performance history in hpx-performance[1033] (`.jenkins/lsu-perftests/upload_history.sh`): a directory `<year>/<node>/<commit date>-<commit>-b<build>` with all results, their medians, the comparison with the references (without the plots, which `perftests_plot.py` can draw again from the results), and the commit (hash, dates, pull request), when the benchmarks ran, the Jenkins build and the configuration in `metadata.json`. `runs.tsv` lists all runs, and `timeline.csv` the medians of all measurements of all runs, which the README of the repository shows as a graph per benchmark over time (drawn by `tools/perftests_ci/perftests_timeline.py` with every new run). `tools/perftests_ci/perftests_history.py` rebuilds `timeline.csv` from the run directories of a clone of the repository, optionally for one node, one benchmark or a range of dates.

Issue tracker

If you stumble over a bug or missing feature in *HPX*, please submit an issue to our *HPX* Issues[1034] page. For more information on how to submit support requests or other means of getting in contact with the developers, please see the Support Website[1035] page.

Continuous testing

In addition to manual testing, we run automated tests on various platforms. We also run tests on all pull requests using both Github[1036]. You can see the dashboards CDash HPX dashboard[1037] .

2.10.5 Using docker for development

Although it can often be useful to set up a local development environment with system-provided or self-built dependencies, Docker[1038] provides a convenient alternative to quickly get all the dependencies needed to start development of *HPX*. Our testing setup on Github[1039] uses a docker image to run all tests.

To get started you need to install Docker[1040] using whatever means is most convenient on your system. Once you have Docker[1041] installed, you can pull or directly run the docker image. The image is based on Debian and Clang, and can be found on Docker Hub[1042]. To start a container using the *HPX* build environment, run:

```
$ docker run --interactive --tty stellargroup/build_env:latest bash
```

You are now in an environment where all the *HPX* build and runtime dependencies are present. You can install additional packages according to your own needs. Please see the Docker Documentation[1043] for more information on using Docker[1044].

> **Warning**
>
> All changes made within the container are lost when the container is closed. If you want files to persist (e.g., the *HPX* source tree) after closing the container, you can bind directories from the host system into the container (see Docker Documentation (Bind mounts)[1045]).

2.10.6 Documentation

This documentation is built using Sphinx[1046], and an automatically generated API reference using Doxygen[1047] and Breathe[1048].

We always welcome suggestions on how to improve our documentation, as well as pull requests with corrections and additions.

Prerequisites

To build the *HPX* documentation, you need recent versions of the following packages:

- `python3` (3.9 or later)
- `sphinx` 7.2 or later (Python package)
- `sphinx-book-theme` (Python package)
- `breathe` 4.36.0 or later (Python package)
- `doxygen`
- `sphinxcontrib-bibtex`
- `sphinx-copybutton`

If the Python[1049] dependencies are not available through your system package manager, you can install them using the Python package manager `pip`. We recommend using a virtual environment:

```
mkdir -p build
python3 -m venv build/.venv
source build/.venv/bin/activate
pip install \
   "sphinx>=7.2" "breathe>=4.36.0" \
   sphinx-book-theme sphinxcontrib-bibtex \
   sphinx-copybutton
```

You may need to set the following CMake variables to make sure CMake can find the required dependencies.

`Doxygen_ROOT:PATH`

Specifies where to look for the installation of the Doxygen[1050] tool.

`Sphinx_ROOT:PATH`

Specifies where to look for the installation of the Sphinx[1051] tool.

`Breathe_APIDOC_ROOT:PATH`

Specifies where to look for the installation of the Breathe[1052] tool.

Building documentation

Enable building of the documentation by setting `HPX_WITH_DOCUMENTATION=ON` during CMake[1053] configuration. To build the documentation, build the `docs` target using your build tool. The default output format is HTML documentation. You can choose alternative output formats (single-page HTML, PDF, and man) with the `HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS` CMake option.

Note

If you add new source files to the Sphinx documentation, you have to run CMake again to have the files included in the build.

Style guide

The documentation is written using reStructuredText. These are the conventions used for formatting the documentation:

- Use, at most, 80 characters per line.
- Top-level headings use over- and underlines with `=`.
- Sub-headings use only underlines with characters in decreasing level of importance: `=`, `-` and `.`.
- Use sentence case in headings.
- Refer to common terminology using ``:term:`Component` ``.
- Indent content of directives (`.. directive::`) by three spaces.
- For C++ code samples at the end of paragraphs, use `::` and indent the code sample by 4 spaces.
  - For other languages (or if you don't want a colon at the end of the paragraph), use `.. code-block:: language` and indent by three spaces as with other directives.
- Use `.. list-table::` to wrap tables with a lot of text in cells.

API documentation

The source code is documented using Doxygen. If you add new API documentation either to existing or new source files, make sure that you add the documented source files to the `doxygen_dependencies` variable in `docs/CMakeLists.txt`.

Adding new API documentation

When you add new public APIs to *HPX*, follow these guidelines to ensure the documentation is correctly generated and easy to use.

[1053] https://www.cmake.org

Documenting headers

At the top of a new header file, include the standard Doxygen documentation block. For example, if the new feature is called *my_new_feature*, you should:

- List the name of the new file under `\file`.
- Specify the page name with `\page` (e.g., `hpx::my_new_feature`).
- Reference the existing header that will include your new file under `\headerfile`.

```
/// \file my_new_feature.hpp
/// \page hpx::my_new_feature
/// \headerfile hpx/existing_header_of_new_feature.hpp
```

Adding to the public API reference

For the documentation to appear in the generated API reference, add your new API to `docs/sphinx/api/public_api.rst` under the appropriate table (usually "Functions") for the relevant header (for example, `hpx/existing_header_of_new_feature.hpp`).

Including examples

Do **not** inline examples in the API reference. If you want to provide an example of how to use the new API, there are two recommended options:

1. **Documentation page option** Edit an existing relevant manual page to explain the new functionality and include a code example. Use this option if you want to provide additional context about how the API works.
2. **Standalone examples option** Create a separate example under `docs/sphinx/examples/`. Examples in this directory are typically more comprehensive and executable, making them suitable for richer or more complex scenarios.

2.10.7 Module structure

This section explains the structure of an *HPX* module.

The tool create_library_skeleton.py[1054] can be used to generate a basic skeleton. To create a library skeleton, run the tool in the `libs` subdirectory with the module name as an argument:

```
